EDITORIAL

T. A. RICKARD, Editor

SELF-SUFFICINGNESS of the mineral resources of this country is emphasized by the Secretary of the Interior in a recent report. He points to the fact that a battleship or an automobile can be built entirely from the products of American mines. The tires of the automobile are excepted, for rubber is not an indigenous product, and will not be until the synthetic article can be manufactured. For the rest, this country produces 55% of the world's copper, 40% of the coal and iron, 32% of the lead and zinc, but no tin or nickel worthy of mention. However, neither need be used in the construction of either the battleship or the automobile, for tungsten, manganese, and vanadium can be substituted for the nickel, and zinc for the tin. Thus Mr. Franklin K. Lane's boast is justified.

THIS PAPER is devoted to the technology of mining and to the advancement of the mining profession, therefore it rejoices in the progress of the one and the prosperity of the other, yet we regret often in these history-making days that the scope of our function restricts us from touching upon wider and more acutely controversial subjects, of far greater importance to the world at large. To dwell upon the prospects of good business in this tragic time does indeed bear the look of gross materialism. We must accept our limitations, otherwise these pages might become filled with non-technical discussion. May we be permitted to quote just this from Mr. E. S. Martin: "Whether there are more people in the world or less, whether they are fat or lean, whether they are Fords or oxen, makes no vital difference; but whether men shall be willing to die for what they believe makes all the difference between a pigsty and Paradise. Not by bread alone, Henry, shall men live." And is it not also true, as the Colonel of Rough Riders has said, that "the man who is too proud to fight is in practice always treated as just proud enough to be kicked." In other words, we wish that our national prosperity were better deserved. It is the old and iterative question that like Banquo's ghost rises to chill the gladness of the feast: can we industrialize our lives without commercializing our souls? That is the problem of American democracy.

AMONG the best features of the recent Exposition was the co-operative metallurgical exhibit made under the management of the U. S. Bureau of Mines. In connection with this exhibit a number of investigations into definite metallurgical problems were started under the auspices of a special committee organized by Mr. Charles E. van Barneveld, the chief of the Mines and Metallurgy department of the Exposition. By a happy coincidence Mr. van Barneveld was appointed professor of mining in the University of California while still responsible for the work above mentioned, so that he was able, aided by the gentlemen of the Bureau of Mines, to arrange for a continuance of the research at the University. Among the problems to be studied are (1) the chemistry of roasting sulphide ores in the presence of water vapors, (2) the absorption of sulphur dioxide in various absorbents, (3) the distillation of sulphur from sulphide ores, (4) the thiogen process, (5) the loss of copper in reverberatory-furnace slags. The chemical work is being done by Mr. L. H. Duschak and the pyro-metallurgy by Mr. A. E. Wells. Moreover, Mr. G. H. Clevenger will proceed with hydro-metallurgical investigations at Stanford University, among the problems assigned to him being (1) sizing tests, (2) cyanidation of refractory silver minerals, and (3) the standardization of analytical methods in mills. All of this, of course, is much to the point and promises to be of direct benefit to the mining industry.

LABOR will be a determining factor in the prosperity now promised to the United States. It is time for the managers of mining and smelting companies to recognize the grave danger that may shatter their hope of successful effort if they fail to face this basic problem frankly. The higher cost of living will cause a logical demand for a rise in the scale of wages. If labor shares the loss of capital in bad times, it should share the larger profit in good times. The obvious thing to have done was to fix a minimum wage during a period of depression and then to make an increase based upon the relative increment of profit in periods of commercial affluence. It is a mistake to postpone the adjustment until it is extorted by the violence of a strike. We do not follow such a plan in our dealings with members of a staff, whether in the office or at home. An attempt should be made to promote a feeling of reasonableness and mutual consideration. Now is the time to start. If only the suspicious attitude of labor to capital could be modified by genuine fair dealing, it would be possible not only to soothe labor unrest but render nugatory the conspiracies of the anarchistic organizations that thrive on the unthinking antagonism of managers and men. Both employer and employee are destined to prosper exceedingly in the near future if they can agree to be reasonable; both may taste the sour grapes of disappointment if they antagonize each other needlessly. It is useless for the day's pay man, and it is stupid of the captain of industry, to think that either can exorcize this

devil of disquiet by shutting his eyes and mumbling the old platitudes. Let them get together to the good of both and the well-being of the community.

REVISION of the mining law will receive the support of the Secretary of the Interior, judging by the remarks in his annual report, in which he says that "the old code is so elaborate and complicated that the best of brains cannot tell what the law is. The truth seems to be that between mining engineers and mining lawyers the rules of the game have been refined into obscurity, and if Congress were to say to the President that he might select three men familiar with mining laws and miners' difficulties to suggest a new mining code to Congress, it would, I believe, be giving in earnest a new freedom to the mining industry." This is of good omen for the success of the steps taken at the recent representative meeting at Washington under the auspices of the Mining and Metallurgical Society of America, on which occasion resolutions were passed recommending thorough revision of the mining law by a Government Commission composed of five members, one representing the legal profession, one representing the Department of the Interior, and three men actively experienced in the mining and acquisition of mineral land. In order to further the best interests of the mining industry in this matter, it was further resolved to create a permanent committee on mining law revision, this committee to consist of five members from the Mining and Metallurgical Society, five from the American Institute, and five from the American Mining Congress. We congratulate Messrs. H. V. Winchell, Curtis H. Lindley, John W. Finch, and our other friends on their successful effort. May it succeed!

The Outlook

Watchman, what of the day? We stand on the threshold of a new year, while the shadows of the dawn are still about us. In the east, whence light should come, we see black darkness riven with lurid lightnings, and through the gloom is heard the sound of a great weeping. In the west, where day should wane, we see a brightening, a growing radiance that presages the sunshine of happier hours.

Indeed, the people of the United States at the beginning of 1916 may well wax rhapsodical when they remember how deep was their dismay and how great their confusion only twelve months ago. Then the stock-markets were closed to prevent hysterical liquidation, finance was disorganized by a break-down of international exchange, mines, mills, and factories were working half-time, a gathering mass of unemployment threatened general distress, and worse than any actual evil was the fear of the future. Now, the stock-markets are pulsating with excitement, industrial activity has been resumed vigorously, business is expanding mightily, there is work for everybody, and a convincing optimism pervades the air. Confidence has been restored. Money is plentiful, because Europe has sent us a plethora of gold in return for the grain, metals, and other supplies that we are selling at an unprecedented rate. The steel industry, that barometer of business, is booming. Even the railroads are beginning to recover, and in some cases are smothered by traffic. Idle cars are as scarce as idle men. Mining is in the ascendant, for the world is consuming metals of every kind.

For the moment, all is serene; what of the future? Is the astonishing business in munitions to collapse suddenly at the first authentic breath of peace and will the collapse bring down a mere house of cards founded on a fictitious trade? Will the rapid accumulation of gold induce a fever of speculation and an orgy of extravagance just when the rehabilitation of Europe will bring us into keen competition with newly organized masses of relatively cheap labor? It is well to consider these questions and to pause in our jubilation. The happy go-lucky or *laissez faire* habits of this unorganized democracy may verge at times on the edge of industrial anarchy. A policy of simple drift may bring disaster. It is the part of a wise man or a sagacious community to look ahead and steer a definite course.

So far, so good. Neither a welter of speculation nor a debauch of extravagance has overcome this country, as yet. The public has been warned and has taken the warning to heart. Wall Street is not the United States. The average citizen has not gone drunk with a crazy optimism; on the contrary, he is asking seriously what he is to anticipate. He sees rocks ahead and is willing to be piloted. It is generally realized that the outstanding problem is to shift the intensified activity in the abnormal manufacture of munitions and other exports of war to the up-building of domestic trade and the creation of new channels of peaceful commerce abroad. This is being done. War orders are playing a steadily decreasing part in our prosperity. The profit made by them is being diverted to the renovation of manufactories in need of working capital and to the starting of industries of a less ephemeral nature than the making of shells and howitzers. Purely domestic development is receiving proper attention. Successful efforts have been made to establish commercial relations with South America and other countries hitherto accustomed to do the chief part of their business with Europe. This justifies the expectation that the end of the War will mark the beginning of a new prosperity based upon logical development. The United States will be the only large industrial organism in a condition to supply the wants of the countries devastated and depleted by war. The loss of capital and of men in Europe will be so crippling as to compel an insistent call for the manufacturing, agricultural, and metallic products of this country. Not that it will be all plain sailing, for the adjustment of international exchange, the rise in American wages, the higher cost of living, and other factors will make big perturbations. On the whole, however, the outlook is good, particularly for metal mining.

We see no reason to amend the forecast presented to our readers several months ago in regard to the demand for metals in the near future. Later events have been

confirmatory, as well as the prognostications of sundry authorities eminent in finance and trade. The consumption of the base metals in the making of munitions is anomalous, of course, but it will become a less decisive factor as industrial development gains ground. As against the loss of this market on the declaration of peace we can place the resumption of the usual demand from the countries now entirely closed to American exports. Whatever the decision of the sword, Germany will continue to be a great industrial country. Austria also, whether aggrandized or partitioned at the close of hostilities, will resume dealings with the United States. Of the copper produced in this country, about 30% goes normally to Germany. Besides the normal consumption there will be, when peace supervenes, a replacement of at least a part of the metal taken out of ordinary use by the exigencies of war. The whole of the American lead production is usually required for home consumption. In 1914 exports of domestic lead, amounting to 58,700 short tons, were made to Europe for the first time in many years. The War has interrupted the smelting of foreign ores and concentrates both in Belgium and in Germany, cutting down the output from Australia, more particularly, where domestic smelting is now being stimulated by the State regulation of mineral exports. At the conclusion of hostilities, there should be a demand from Europe for American lead to supply deficiencies created by wastage and destruction. This applies also to zinc, which, like lead, is produced in this country at a rate only slightly in excess of consumption. That excess, however, is increasing. During 1913 and 1914 it was 14%; in 1912 and 1911 consumption and production were just about equal. The War killed the Belgian zinc-smelting industry and interfered with that of Germany. Since hostilities began the successful development of the leaching and electrolytic precipitation process in this country promises to become a big factor in cheapening the production of the metal and in aiding competition with the European smelters. The continued progress being made in the metallurgical reduction of the base metals tends to strengthen the smelting industry of the United States, thereby establishing an increasingly better market for the produce of the mines at home and also abroad. With the growth of domestic consumption consequent upon the expansion of domestic industry and the exceptional demand from Europe resulting from the tremendous work of reconstruction, there should be a splendid market for the metals during the coming years. By that we do not mean that the present prices of the metals will persist undiminished; that would be too much to expect, and would provoke a corrective, in the form of substitutions, likely to be injurious in the long run. The price of zinc, for example, is such as to hurt the galvanized iron trade and cause a demand for a substitute plating. Severe discountings of existing prices for copper and zinc, more particularly, are possible without serious injury to legitimate mining. Copper at 17 cents, and zinc at 8 cents would afford ample margin for handsome profits. Allowing room for such contingencies, the outlook for metal mining is good.

Dry Mining

We are glad to be able to give our readers a timely article on Oatman, the resuscitated goldfield in Arizona. It is being featured in the daily press as a new discovery, but in reality it marks the revival of activity in the desert country around the old Gold Road and Tom Reed mines, brought into fresh prominence by the development of a new rich mine, the United Eastern. The resuscitation or revival has been effected without the aid of alcoholic stimulants, for Oatman is a dry camp. In his happy presentment of the picturesque features of this new rush, Mr. Frank H. Probert lays emphasis on the fact that prohibition renders Oatman wholly unlike the mining excitements of former days. Undoubtedly the result is the loss of a certain kind of pseudo-romantic glow such as glorifies the Outcasts of Poker Flat and the Idyll of Red Gulch, but that is something more essential to frontier poetry than to human progress. It seems strange to the veterans of the West to think of an Arizonan boom devoid of the necessaries of exhilaration, and it seems equally strange that in the new year our friends in Colorado should be facing a similar break with all the traditions of the past, for their courts also have decided that prohibition must be absolute. Our correspondent at Denver views the prospect with ill-concealed dismay, while recognizing frankly that the open saloon is an institution not essential to civilization. The West is outgrowing the recklessness of youth and no longer confuses good fellowship with a superabundance of cocktails. So we shall neither sneer at, nor commiserate with, Oatman. The money that would have gone to the mixologists and distilleries will be kept for the more productive purpose of exploring the desert rocks in search of the precious metal. And the painfully sober prospector is doing it vigorously and effectively, according to all accounts. The geological structure offers no short cuts to wealth, as is clear from the preliminary diagnosis of Mr. Probert. Much more investigation is necessary, as he indicates while offering some pertinent suggestions. Hitherto some of the best orebodies have been found at a distance below the surface, thus creating the pleasant delusion that enrichment is a consequence of depth. One swallow does not make a summer—nor even a drink—at Oatman; likewise the fact that two shafts did not strike good ore until 300 feet was reached does not constitute evidence on which to build the idea of an ore-bearing horizon at a fixed distance from grass-roots. Of course, we appreciate the fact that, in determining the probable value of a prospect, the postponement of the critical point until the workings have reached a given depth is not without practical value in ensuring a reasonable amount of vertical exploration. In a district where the orebodies have a decided pitch and are softer than the encasing rock, such a supposition tends to promote systematic search. The story of Goldfield proves that a bonanza may fail to poke its head above the cactus. But we do deprecate the assumption, already current in brokerage

literature that a poor showing at surface is not discouraging, nay, almost furnishes proof of the richness of the vein at 400 feet, for that is what happened in the United Eastern, so it is said. However, the humor of the position is evident. We believe that the enforced sobriety of the mining population of Oatman will not be without effect in modifying the imagination of the promoter and in giving legitimate mining a fair chance. Interesting developments may be expected in this part of Arizona during 1916.

Mining at Juneau

We note that our contemporary at New York, the *Mining Journal*, has had something further to say concerning the exploitation of the big lode that traverses the Gastineau and Juneau groups of claims in Alaska. As is stated truly, the subject is one of interest "not only to thousands of investors in the shares of these companies, but also to the engineering profession." We are told that "the problem itself involves the mining and milling at a profit of ore that is expected to average only about $1.50 per ton." No; the problem is to ascertain whether the expectation of a $1.50 yield per ton is warranted under given conditions; to determine how small veins of quartz containing $6 per ton in gold and dispersed over a big width of barren rock can be mined most profitably. The engineer's duty is to find out to what extent selection and sorting can be applied economically. Of course, the small gold-bearing veins traversing the slate lode could be mined and milled selectively at a cost about equal to their assay-value and in excess of their yield; on the other hand, the whole width of lode-matter could be mined indiscriminately and milled unsorted for a cost of about 50 cents per ton and a yield of perhaps 80 cents per ton, a margin sufficient to pay interest on the cost and depreciation of a suitable plant. Somewhere between these extremes is the economic limit that coincides with the maximum of profit. The engineers of the Juneau plan a $1.20 recovery as best suited to the conditions in that mine; the Gastineau management planned a $1.50 recovery, which now, by such accidents as are a part of the sport of mining, has been reduced to $1 per ton. Our learned contemporary says that the one company intends to adopt "bulk mining," while the other applies "selective mining." This comparison is misleading. Both are aiming to restrict their stoping to mill-ore having the average yield that is most profitable, after balancing the three inter-dependent factors of tonnage, yield, and cost. The Juneau is selecting places suitable for bulk mining; the Gastineau is selecting places suitable for preferential mining, or sorting.

Another contemporary, usually well informed, the *Boston News Bureau*, publishes an article on the subject with the sub-title 'An Investment Proposition.' Both the New York and the Boston paper talk about the enterprise as an 'investment,' which, of course, it is not. It is, or may be, a highly attractive speculation, with all the risk inherent to gold mining. The promoters may call it an 'investment' when addressing an unsophisticated public, but the engineering profession must be well aware that a wasting asset of uncertain life affords no basis for investment. However, we have digressed. The Boston paper asserts further that it is "a minor problem to balance ore mining below a dollar per ton by ore running up to $3 or $4 per ton, and make an average of $1.50 per ton." The problem is one for a miner, not a minor. It constitutes the crux of the whole matter. We are told how "of course, the unexpected happened" and a collapse of ground spoiled some rich stopes. That, my dear Sir, is part of the problem in this kind of mining and it is one of the things that militate against the 'investment' idea. The Boston scribe says that "the ore is disseminated in fine particles through layers of slate, meta-gabbro, and schist," but he has not learned his lesson correctly. The wording smacks too much of a copper deposit in Utah or Arizona, and is not applicable to this Alaskan lode, in which the rock is enriched by gold in irregular veins of quartz, not by chalcocite pervading monzonite-porphyry. The gold is not in the slate, schist, or meta-gabbro—nor in Shadrach, Meshach, and Abednego. Meanwhile nothing is said about that horse of schist that proved so destructive to the estimate of a large block of ore-bearing ground. Such happenings are part of the mining adventure and should not be exaggerated, but they inject an element of uncertainty into those approximations on which the exploitation of mines is based. These two big enterprises near Juneau require the most careful study of the most experienced engineers, and they are getting it, as would be better appreciated if the voice of the broker were not so loud.

Reverting to the explanations of the New York periodical, we find a curious blunder. The statement is made, in its issue of December 18, that the engineers of the Juneau "are going to adhere to the conventional stamps" while the Gastineau management has introduced the use of rolls into its mill. Our readers are better informed on this phase of the subject, for we discussed it at length in our issue of October 16. In the Gastineau mill the ore is reduced in a large jaw-crusher, passing thence to a series of gyratory crushers, and then in succession to roughing rolls, finishing rolls, and tube-mills. The Juneau mill has been designed on the same lines, except that ball-mills are substituted for the rolls. No stamps are to be used. Indeed, as we stated three months ago, a series of experiments is being made at Treadwell also with a view to determining whether it would not be advantageous to employ ball-mills, instead of stamps, in case a new central mill is erected to treat the output of the three contiguous mines on Douglas island. In these and other matters this part of Alaska is destined to afford much of interest and instruction to the mining profession. The men in control of the work at the three principal groups of properties—the Treadwell, Gastineau, and Juneau—are among the most experienced and resourceful in this country. If there be any rivalry, as our contemporary takes pains to suggest, we do not doubt that it will simply serve to give zest to the application of technical science on a splendid scale.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Valuing Complex Ores

The Editor:

Sir—I have noticed from time to time, articles by many different engineers and metallurgists, on the subject of mine valuation. I do not recall having seen anything in the nature of a discussion of ore valuation. Since my work for the past 13 years has been almost entirely along the lines of valuation of complex ores, especially those containing zinc, I propose to open the discussion, if indeed the subject is deemed worthy of such, by submitting the following:

Having worked out the treatment of several complex ores and having attempted to work a treatment for several hundred others, I have taken a specific case which has come to my personal attention and which, I believe, will serve the purpose of argument, more completely perhaps than a general discussion of the subject.

During the greater part of the present year, owing to increased activity in the zinc industry, engineers have had many occasions to examine and report on mines, the value of which has depended to a large extent upon the zinc content of the ore. The mine is sampled and the ore measured to a point where the engineer finds a certain number of tons carrying a certain amount of gold, silver, copper, lead, zinc, iron, and any other metal that can be recovered and sold. It is at this point in his examination that an understanding of the methods of treatment to be employed that will effect a commercial saving of the metals, the cost of such method, and the marketing of the products, is fully as essential to the correctness of his findings as is the knowledge of methods for sampling and measuring the ore. It is at this point that the assayer has found himself in a most embarrassing position, not on account of his inefficiency as an assayer, but because he has not the facts at hand upon which to base a sound opinion as to the value, in dollars and cents, of the ore upon which he has determined its metal contents. I have seen assay-certificates from reputable assayers which showed fully the metal contents, and, in the space for that purpose, was shown a value, calculated from the analysis. In many cases these 'values' have been found to represent the metal-values, based upon the current quotations for the different metals, and the ounces and pounds of the same metals delivered at New York. It is needless to say that this method is misleading and may result in financial disaster if further investigation is not undertaken.

Many engineers have attempted to estimate such ore-values by allowing 'liberal' losses. By this method great mistakes may be made, chiefly because the losses allowed have not been sufficiently 'liberal.' It is my intention to show that there is no possible way by which these losses can be estimated. They must be determined accurately, and in most cases, they will be found to be surprisingly large.

Some months ago, I was asked by an engineer who had finished an examination, what percentage of saving could be reasonably expected by the most modern practices. I was told that the ore 'ran' $12 per ton, allowing $20 for gold, 50c. for silver, 50c. per unit for lead, and 60c. per unit for zinc. He had not assayed for iron, since it had little value. I was unable to make an estimate, because I did not know, nor did any one know, what grades of products could be made or how much of the gold and silver would be found in the zinc product. These facts, which are absolutely essential, can be determined, and must be determined, before the value of the mine can be definitely fixed.

To illustrate how difficult it would be to make an estimate of this kind, I submit the following table to show what products can be made and what money will actually be received at a certain stage of the metal market, for a certain ore.

	Weight, %	Gold, oz.	Silver oz.	Lead, %	Zinc, %	Iron, %	Silica, %
Original ore.....	100	0.07	9.00	8.00	16.00	7.00	46.00
Lead product.....	8	0.32	45.00	68.00	5.00	6.00	2.00
Percentage saved.		36.50	40.00	68.09	2.50	6.80	0.30
Iron product.....	14	0.22	17.00	8.00	11.00	32.00	6.00
Percentage saved.		44.60	26.40	14.00	9.50	64.00	1.80
Zinc product.....	26	0.02	6.50	2.60	48.00	5.00	10.00
Percentage saved.		8.50	19.00	8.60	78.00	18.50	5.60
Slime	7	0.04	11.00	7.00	12.00	6.50	49.00
Percentage saved.		4.00	8.50	6.10	5.20	6.50	7.40
Tailing	45	0.01	1.20	0.60	1.70	0.70	86.00
Percentage lost...		6.40	6.00	3.30	4.70	4.20	84.90

It will be seen that the total concentrate carries 89.6% of the gold, 85.5% of the silver, 90.8% of the lead, and 90.1% of the zinc. This certainly can be called a high saving. The original ore, estimated upon metal contents and quotations, with gold at $20, silver at 50c., lead at 4½c., and zinc at 5c., has a value of $29.10. Estimated with gold and silver the same and lead at 50c. per unit and zinc at 60c. per unit, it has a value of $19.50. When these products are sold, however, they will be sold about as follows: In lead concentrate we receive $19 for gold, 47½c. for silver, 3¾c. for 90% of the lead (wet, less 1½), and 10c. for excess iron. We pay $3 freight and no treatment charge. This leaves us $63.75 per ton net, or $5.10 per original ton.

Iron concentrate will bring the same prices for gold, silver, lead, and iron. We pay the same freight and about $5.50 for treatment. This leaves $11.31 per ton net, or $1.57 per original ton.

The zinc concentrate, with spelter at 5c., and $5.50 freight, will net $12.30 per ton or $5.02 per original ton.

These net receipts amount to $11.69 per original ton, which is 31% of the assayer's figure and about 60% of the engineer's.

A careful analysis of the above figures will show that we have received net $11.38 per ounce for gold, 25.2c. per ounce for silver, 2.09c. per pound for lead, and 1.57c. per pound for zinc, which figures may safely be applied to this particular ore so long as the grade does not change materially. The contracts upon which I have figured settlements may vary to some extent, but the general result will be about the same.

Thus it will be apparent to the investor and to his engineer that the metal contents and market prices of the metals cannot be used as a basis of calculation for valuing ore until it is fully and definitely known where these metals will be recovered and what prices will be received for the various products.

A. M. Plumb.

Denver, December 18, 1915.

Why Is Flotation?

The Editor:

Sir—Please allow me to contribute to 'Why is Flotation?' for I have worked on the subject more or less since 1903.

In the effort to elucidate flotation, a common error is made of trying to fit one explanation to both film, or skin, and frothing methods. The surface tension theory will fit the skin method, but cuts no figure with frothing. This will be seen as we progress.

To begin, what is a bubble? Webster defines it as "a small body of air surrounded by a liquid." Being lighter, it rises through the liquid, and on reaching the surface presses upward, not against the liquid, but a fluid as light as itself. There is no further bar to its progress, so it escapes and joins the aforesaid fluid, known as the atmosphere.

In this case, differences of specific gravity rule, which is precisely what governs conditions when oil in a finely-divided state is released below a water surface. This strong upward pull of both air and oil, due to gravity differences between them and water, is of prime importance in practical flotation work.

If a close-fitting glass-plate is introduced into a tank, just under the water surface, air and finely divided oil will collect against it, when they are released from below. If a sufficient quantity of each is used and the entire space on the under side is covered, an addition will result in the gradual displacement of the water from the area, and a collecting together of two large separate globules of air and oil. Remove the plate, and the air, having in the large globule the sum of the combined bubble pressures, escapes to the atmosphere, while the oil tends to diffuse itself over the surface of the water.

Continuing our experiment, we have now an elastic film of oil on the water surface, instead of the glass plate. A further addition from below of both oil and air causes the former to join the film, while the latter, in its effort to unite with the atmosphere, impinges sharply against the lower surface of the oil film, raising it upward in a partly spherical form. If the oil film were now as solid as the glass plate, no doubt the same collection into separate globules would obtain. The point, however, to be noted, is that each factor in the experiment remains separate, namely, oil, air, and water.

We left the bubble slightly above the water surface and against the oil film, but not detached. On renewing the flow of air and oil from below, we find that the pressure of others will lift the bubble completely out of the water into the oil. When the lower part of the sphere is high enough the oil ends will join and we now have a bubble detached from the water, resting in oil and on the water surface. It has no water in its composition, floats easily, and holds its shape and character in the open air, whereas previously it could only exist under water.

Wherefore, with a continuous supply of oil and air, bubble manufacture will proceed until the surface is covered with a thick coherent mass called a 'froth,' and a superficial study will show that surface tension, as commonly defined, plays no part in the phenomena.

In my opinion there is no selective action between oil and certain constituents of an oil pulp. Each particle in the pulp takes its oil coating impartially, but some, like the oxides, carbonates, and silicates, part with it quickly in the presence of water, while others, like the sulphides, cling to it obstinately. A sulphide particle, satisfied as to its oil requirements, gives up no part of its oil coating to feed the surface film, so necessary for the preservation of the air bubble, this factor being furnished by the oil from the oxides, carbonates, and silicates. Consequently, when submerged in water, the upward pull of the oil coating of the sulphide particle keeps it in a state of unstable buoyancy. It should be noted at this time that with frothing methods, the oiling takes place in the advance stages of treatment, and from the above we glean that it is important that all constituents be coated equally.

Agitation in frothing work serves to introduce air into the water, and to a less degree keeps the entering pulp in partial suspension therein. The method employed is unimportant in this discussion.

In the light of the above reasoning, what happens when a froth-flotation machine is started and in operation?

On starting the agitators in clean water, myriads of small bubbles form, due to air beaten in or furnished otherwise. Their natural path is upward, and in clean water they break at the surface.

But a change takes place when the ore pulp, previously oiled, is added. The pulp particles on entering the water, quickly give up the oil from the oxides, carbonates, and silicates, that forms the preserving surface

film. The sulphides, being in a state of unstable buoyancy and clinging obstinately to their oiled coatings, are kept in suspension or driven upward by the agitation. In moving through the water they cross the path of innumerable air bubbles, and find no difficulty in annexing enough to assist the buoyancy. There is drive enough to impinge them violently against the oil film and the pressure of myriads following, gives force enough to elevate them above the water surface into the familiar froth. The gangue minerals, having no buoyancy, sink.

In practical frothing work, the design of the principal factors is of importance. The size of the agitation-boxes should be the smallest possible compatible with the tonnage-capacity desired. Agitators should be so gauged and designed as to form a uniformly sized bubble, large enough to have the maximum transporting power without reducing the number thereof. The oil should be of a nature allowing maximum stretch at the surface, and just tough enough to stand wear and tear. The lower its specific gravity, in combination with the other qualities desired, the greater its pulling or lifting power. Oiling should be done during grinding, if possible, as it gives a better mix.

Heating the water thins the oil and lessens the consumption, but gives a more delicate bubble covering. It has this advantage, that it heats the air inside the bubble, increasing its pulling or lifting power, and should enable the treatment of coarser sizes, but this may be modified by the fact of its tending to rob the sulphide of the oil coating, thus reducing the pull.

I think acid roughens and increases the sulphide area, allowing more oil to adhere, and assisting buoyancy. Possibly it generates a gas that acts like air. The old theory of calcite being necessary in the pulp for bubble-lifting is doubtful. Carbonic acid gas is heavier than air.

A lot of study has been bestowed on oils, but very little on the other factors that are nearly as important. Machines or methods of agitation designed to improve and control the uniform size and number of the bubbles have been little considered.

As to lifting power or pull, I can remember a painful experience of my boyhood days, when the janitor caught us blowing soap bubbles, by holding a soaped spool tightly over a gas-burner tip. Filling the interior of the bubble with illuminating gas sent it out of sight with no effort. When caught, we had the school population gazing heavenward, and the ceiling of the room was one mass of bubbles, some of which lasted for an hour.

In the pneumatic systems of agitation the addition of a small quantity of illuminating gas, may give as good pull as heating.

In 1904, I think, while experimenting at Sandon, B. C., I used a small tank and about 15 Daniels cells for bubble-making purposes. With a weak electrolyte, a copper plate on one side and a bunch of hay-wire on the other, I found that by stirring in an oiled pulp I could get a thick skin of bubbles. My apparatus was limited and soon exhausted the electrolyte, but I got a good flotation after the froth order. I remember the speed and size was marvelous and under close control. The batteries belonged to the telegraph company, I was an underpaid operator, and the fool superintendent was woefully obstinate, ignorant of research, and painfully insistent on the restoration to service of his 15 cells. The combination floored me.

I recollect detailing the operation to an Elmore representative soon after, but did not know until Hoover's book, 'Principles of Flotation,' came out that the ideas had been patented in Great Britain. However, that method of generating a hydrogen-filled bubble under close control, with electricity, is open for use in this country. It was not patented here. Who knows but what some genius will utilize it, or the illuminating gas, to fill bubbles that will haul the ore direct to the smelter from the flotation-cell?

GEORGE HUSTON.

Mullan, Idaho, November 12, 1915.

Flotation Residue

The Editor:

Sir—I was much interested in reading the article on 'Disposal of Flotation Residue,' by my friend Wilton Shellshear of Broken Hill, but for the honor of Australia I must differ from him regarding the system of spraying slime over sand-dumps. He says "the idea was first originated in South Africa, and has only lately been introduced into Australia." Strictly speaking, he may be correct, as he speaks of pumping or spraying slime. But I would like to say that I saw slime-residue from a Moore filter (the first one successfully used in Australia) spread over the surface of a sand-dump from trucks at the Occidental gold mine, Cobar, New South Wales, in 1905 or 1906. I think A. J. Chapple, who was then the metallurgist there, will corroborate this. When was this system first used in South Africa? I saw it at New Modderfontein in 1911.

W. MOTHERWELL.

Colorado Springs, December 15, 1915.

GUATEMALA, the northernmost of the Central American republics, has an area of 48,290 square miles, which exceeds that of Pennsylvania. The population is 2,119,165, which is nearly as much as Bolivia, whose area is 15 times as great; the capital, Guatemala City, has a population of 125,000; while the bulk of the people lives in the half of the country lying toward the Pacific, the steamship communication on that coast is less frequent than on the Atlantic side. Although in the torrid zone most of the country is at 4000 to 11,000 ft. altitude, and the climate is comparatively healthy and agreeable. About 60% of the imports comes from the United States, but the bulk of the exports has gone to Germany. The monetary system needs re-organization, and a gold standard would benefit finances. The railroads are owned practically entirely in the United States, but in other lines investment of American capital is small as yet. In Guatemala City the tram-line is run with horse and mule power.

Testing Ores for the Flotation Process

By O. C. Ralston and Glenn L. Allen

INTRODUCTION *Although the subject of testing for flotation has been well presented in T. J. Hoover's book on 'Concentrating Ores by Flotation,' there is need of later information on this timely subject. Much testing has been done in laboratories not connected in any way with the Minerals Separation company, with which Mr. Hoover was formerly associated as metallurgical engineer, and there have been developed methods of investigation that may prove suggestive to many experimenters.

On that account we have compiled data on the subject of testing both from the literature available and from our own experience, as well as from what we have seen in other laboratories. This paper is designed to present the results of this compilation, with a critical discussion of the more important methods now in vogue.

On account of the empirical state of the art of flotation a great deal of testing is necessary before large-scale practice can be commenced on any ore; therefore a small laboratory-machine is necessary in which many tests involving many variables can be made in a short time. The machine must be so designed and so operated that a close approximation to the results possible with full-sized flotation machinery will be obtained. In a mill-plant it is a matter of some difficulty to control conditions through a wide range of such variables as temperature, acidity, quantity of oil, percentage of solids in pulp, fineness of grinding, etc., and as the proper treatment of a given ore can be ascertained only through testing it first, a critique of the testing methods in use is in order.

Many people have had the experience of reading the available literature on flotation testing and of failing to get satisfactory results when the described testing was attempted. To actually witness some good test-work and learn thereby the appearance of froth, the exact manipulation of the machine and froth, goes far toward bringing the beginner to a point where he can test efficiently. None of the literature mentions the fact that it is difficult to get a high percentage of extraction and a high grade of flotation concentrate at the same time. The beginner often strives after both of these things in a single test, whereas he should determine how each can be attained before he attempts to obtain both simultaneously. Furthermore, it is difficult to manipulate a small machine to give as good results as a large one, until after considerable practice. So the small machine is generally pessimistic, compared with the large one. It is practically essential for the beginner to weigh and assay all of his products in order to see if the extraction and the grade of concentrate are satisfactory, where an experienced manipulator can often tell by aid of past experience and the use of a glass or microscope whether he is getting good results or not.

With these points in view, we shall describe first the satisfactory machines and their operation. Then we shall give a more general exposition on what variables to study and what points to observe.

Flotation test-apparatus must necessarily be classified in the same way as large-scale machines, namely, as film-flotation machines, acid-flotation machines, and froth-machines of both pneumatic and mechanically agitated types. Film-flotation, as exemplified in the Macquisten[1] and in the Wood machines, does not seem to have the same wide application as does froth-flotation; hence little need be said about them.

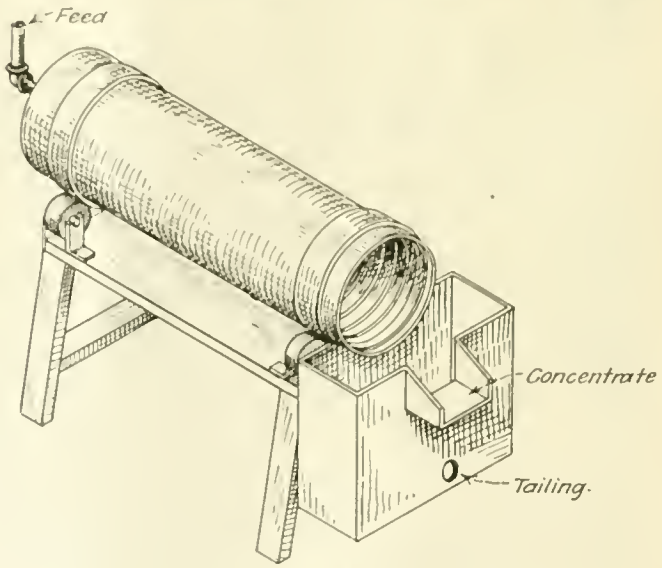

FIG. 1. THE MACQUISTEN TUBE.

FILM-FLOTATION. Macquisten tubes have such small capacity that a single tube is small enough for test-work on a few pounds of ore at a time (see Fig. 1). A small 4-ft. tube is known to give trustworthy results, although a longer one is more desirable. Testing with a Macquisten tube was done for several years in the laboratory of the General Engineering Co., of Salt Lake City, of which company J. M. Callow is president. Since Mr. Callow has begun the exploitation of his own pneumatic frothing-machine this work has been set aside.

*By permission of the Director, U. S. Bureau of Mines. Communicated by D. A. Lyon, metallurgist in charge of the Salt Lake station of the U. S. Bureau of Mines, co-operating with the University of Utah. O. C. Ralston, Assistant Metallurgist of U. S. Bureau of Mines, and Glenn L. Allen Research Fellow of the University of Utah.

[1]M. & S. P., Vol. XCVI, page 414 (1908).

The Wood machine can be built in miniature and for several years a small machine of the type sketched has been used in the plant of the Wood ore-testing works at Denver.[2] This small machine was about two feet long and one foot wide. The method of operation is the same as that of the full-sized machine. (See Fig. 2.)

As neither of these machines has been much used in practice, they are merely mentioned for the sake of completeness. Hoover[3] has recommended a test on a vanning-plaque, so that the sulphides will float off onto

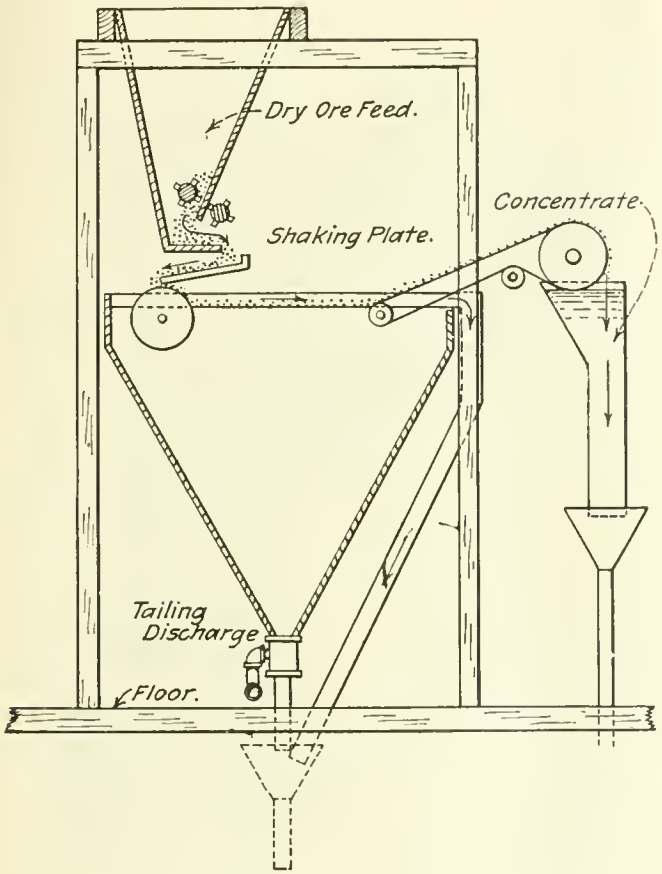

Fig. 2. The Wood Machine.

the surface of the water, but we consider this test of practically no value. Hoover, however, acknowledges that it is merely a test illustrative of the film processes.

In testing ores for the Potter or the Delprat processes, Hoover's text is again the source of information. An illustrative test-tube experiment is pictured in Fig. 3. In another test a 200-c.c. beaker is used with 100 c.c. of 3% H_2SO_4 and brought to nearly boiling temperature. The ore when introduced into this yields a froth composed of sulphides supported by bubbles of CO_2. In case the ore is deficient in carbonate, an addition of as much as 3% of calcite or siderite is made. The froth is skimmed with a spoon as fast as it forms. We have noticed that a great deal of mineral is often lifted partly but never reaches the surface. Consequently extractions are low, although the grade of concentrate obtained is often very good. For practical purposes, however, the test is not of much value. A better test-machine is the small unit shown in Fig. 4. The acid should be allowed to run down through a section of garden-hose to within an inch of the surface of the ore and the ore should be kept stirred with a wooden paddle so that the bubbles

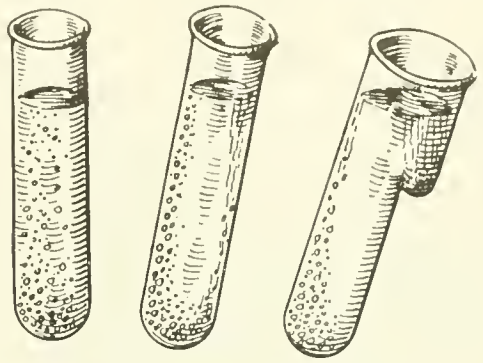

Fig. 3. Test-tubes for Flotation.

of CO_2 generated by the action of the acid can lift the sulphides out of the body of the pulp. The froth formed should be skimmed with the paddle as fast as made, then filtered, dried, weighed, and analyzed. Not many ores yield gracefully to this treatment and slimes give poor extractions. Fines and Wilfley-table middlings are better adapted, and the presence of siderite in the pulp is desirable, as it reacts slowly with dilute acid. From

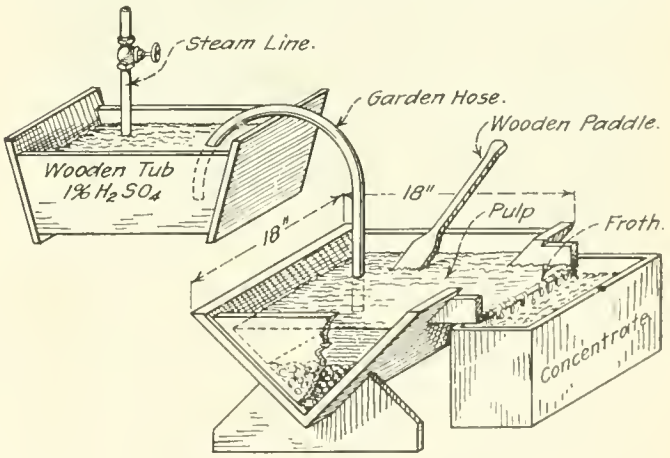

Fig. 4. A Potter-Delprat Test.

1 to 3% H_2SO_4 is best in testing and ½ to 1½% solutions on the large scale will give about the same results. The temperature of the pulp should be maintained at 70°C. by use of a steam jet. Five to ten pounds of ore per test is necessary. The extractions obtained are always lower than in full-sized units. While oil is not necessary in this process it will greatly assist in the flotation, and the addition of a small amount is often of much assistance in test-work.

Mechanical frothing as developed by the Minerals Separation company in England and Australia, and modified by many others, has been one of the most im-

[2]H. E. Wood. Trans. A. I. M. E., Vol. XLIV, pp. 684-701 (1912).

[3]T. J. Hoover. 'Concentrating Ores by Flotation,' 1st edition, page 77.

portant methods of flotation. Therefore the laboratory machinery that has been developed is at as high a state of perfection as any such machinery now in use.

The Janney machine is probably the best designed machine for getting reliable quantitative results on a small quantity of ore. Photographs and sketches are appended (Fig. 5, 6, and 7). It can be seen that the agitation compartment is cylindrical in shape and that its top is surrounded by a froth box, which slopes into a spitzkasten, where the froth can be skimmed. The tailing sinks to a return hole at the bottom, passing into the agitation-compartment again. To provide good agitation, four vertical baffles are attached to the wall of the agitation-compartment, against which the pulp is swirled by the two impellers. Lining the walls with expanded metal lathing or with a coarse-mesh iron screen adds to the thorough mixing that the pulp must receive. The two impellers are on a common shafting, which enters the machine through a stuffing-box in the bottom of the machine. The lower impeller with four vertical vanes is submerged; it agitates and emulsifies the pulp while the upper impeller, likewise with four vertical vanes, acts as a pump to lift the pulp and beat air into it. A pulley and belt connect the shafting with a variable-speed motor.

A dome-shaped lid is used on the machine. A small hole in the top of the dome allows the introduction of oil, acid, water, or other materials without the removal of the lid. The lid is so constructed that it can be turned upside-down with the dome extending down into the froth-box, and in this position it can act as a funnel. The dome rests then on the top of the agitation-compartment and no froth can escape into the froth-box. This allows a period of agitation of the pulp before the dome-top is turned right-side up to allow aerated pulp to overflow into the froth-box and down into the spitzkasten, where the froth can be removed.

A discharge-plug at the bottom of the machine allows the flushing out of tailing after the test has been completed. So careful has been the design of this test-machine that even this discharge-plug is beveled to fit flush with the bottom of the machine and thus afford no dead space in which the solids might settle.

The spitzkasten is long and narrow, in order to permit a deep froth to be formed and to travel over as long a space as possible, before reaching the discharge. This tends to allow more of the entrained gangue to settle out of the mineral froth. The sides of the spitzkasten are of heavy plate-glass, each fastened to a metal-frame by means of screws. The wrought-iron shaft projects through a brass stuffing-box and is supported by a ball-bearing beneath. All the other metal parts are of cast aluminum.

The small variable-speed motor may be of either D. C. or A. C. type. F. G. Janney recommends the use of a General Electric, shunt-wound, direct-current motor, for 230 volts, with a rated speed of 1700 r.p.m. and $\frac{1}{4}$ hp. The impeller-shaft is to be driven at 1900 r.p.m. maximum speed. For speed-control he recommends a General Electric direct-current field-rheostat, with an ampere capacity of 1.25 to 0.063 at 250 volts.

In our own laboratory it was desirable to use the ordinary city lighting circuit of 110 volts, A. C. On that account we have found the following motor satisfactory: $\frac{1}{4}$ hp. General Electric repulsion induction motor, single-phase, 60-cycle, with full speed of 1780 and carrying 4.2 amperes at 110 volts, or 2.1 amperes at 220 volts, depending upon the voltage of the current supplied to the machine, either voltage being acceptable. Speed-control is obtained by the use of an ordinary field-rheostat in series with the motor. Such a motor has a speed varying with the load and with the voltage applied. As the load is practically a constant, the speed will depend upon the amount of resistance in series with the motor. As the majority of laboratories find a city alternating current more convenient to obtain, such a motor is recommended.

The operation of the machine is as follows: It is set up on a bench convenient to the sink and to running water. The motor is set up one foot to the rear with the switch and rheostat placed so that they can be easily reached while standing in front of the machine. A $\frac{1}{4}$-in. round-leather sewing-machine belt is used for drive. The bearings are well oiled, the stuffing-box is properly packed, and some attention should be given to it occasionally in order to see that it is kept screwed tight enough to avoid leakage.

Enough clear water is run into the machine to barely show in the spitzkasten and the motor is started at its lowest speed. A 500-gm. charge of ore ground to at least 48-mesh is added and the cover placed on the machine in its inverted position. (See Fig. 5.) This is done to allow thorough mixing without circulation of the pulp. All or part of the oil and other reagents are now added and the motor brought up to full speed for 30 seconds. The speed is again lowered to the minimum and the cover is turned over into its upright position. (See Fig. 6.) The speed is then raised and water is added through the hole in the top of the lid until the froth in the spitzkasten is nearly at the overflow lip. The ultimate speed of the agitator will depend somewhat upon the character of this froth, as some oils will give a deep persistent froth, while other froths are thin and brittle and allow of more water being added to the machine, as well as more violent agitation in order to beat more air into the pulp. The froth may either be allowed to flow out of the spitzkasten of its own weight or skimmed with a small wooden paddle. It is a good idea to wet the glass sides of the 'spitz' with water while the froth is rising, so that none of the froth will stick to the glass.

The duration of the test is about five minutes with an ore that floats easily, while other ores will require a considerably longer time to allow the entrained gangue to settle out of the froth before it is discharged from the machine. In such cases it is best to hold back the froth until its appearance shows it to be fairly clean. Beginners are likely to dilute their froth with too much

gangue. In a large-sized machine the froth can travel over from four to eight feet of spitzkasten before it is discharged, while in this test-machine it only has a travel of about 10 inches. Consequently, the small machine is liable to yield concentrate of too low a tenor. The same applies to most other machines for making tests on flotation.

The concentrate may be caught in a pan or on a filter. After the test the machine is brought back to low speed and the tailing-plug removed, so that the tailing can be caught in a pan or bucket, or run to waste.

If it is so desired, this rough concentrate can be put back into the machine and treated in the same way as the original sample, or the concentrates from several tests combined to give enough material for re-treatment. If this is done three products are made, namely:

A 'rougher' tailing, to waste.

A clean concentrate, for shipment.

A 'cleaner' tailing or middling, which in actual practice is returned to the head machine.

When these conditions are observed results only slightly lower than those possible with a big machine can be obtained. A test can be run in from 5 to 30 minutes in such a machine with 500 grams of ore in anything from a 3:1 to a 5:1 pulp. The glass sides of the spitzkasten allow close observation of the condition of the froth, and this is a great advantage to the beginner. The small amount of ore necessary for a test is a matter of considerable convenience as fine grinding of the ore in the laboratory is often irksome. The aluminum casting is little corroded by either acid or alkaline electrolytes. The return of pulp from the 'spitz' to the agitating-compartment allows the material to be treated until all mineral has been removed without stopping the machine, so that a single treatment yields a clean tailing. However, a second treatment of this 'rougher-

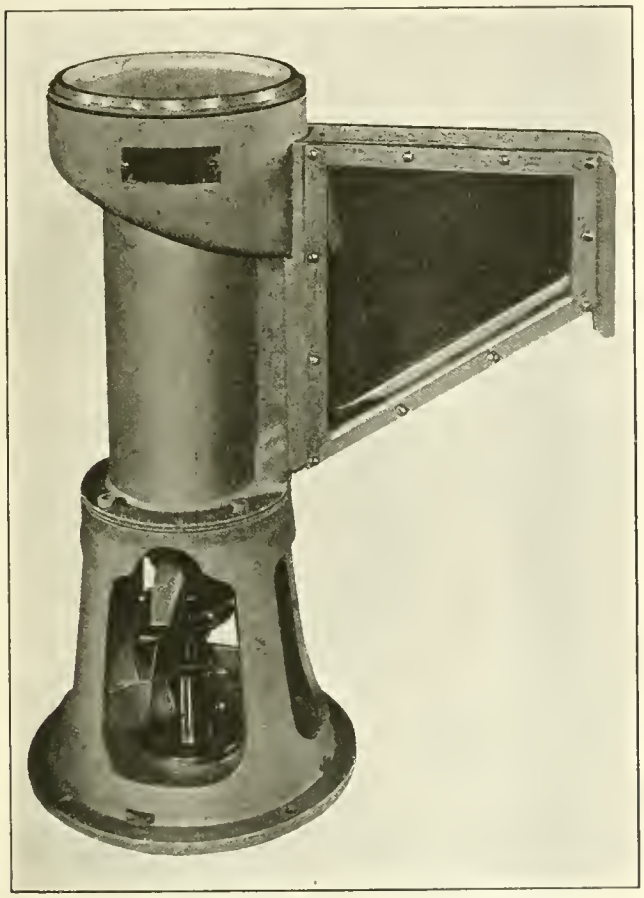

FIG. 5. THE JANNEY MACHINE. COVER INVERTED.

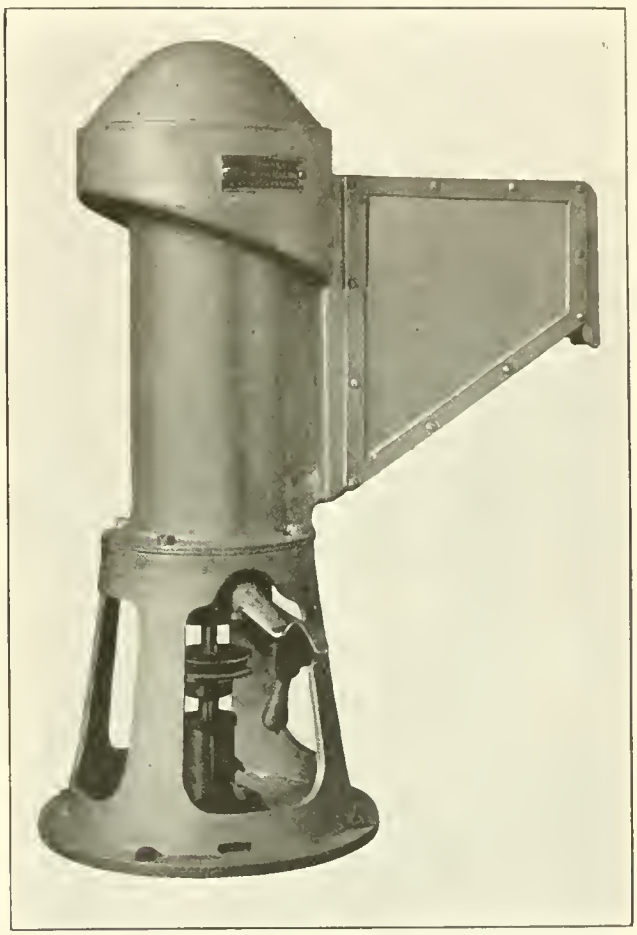

FIG. 6. THE JANNEY MACHINE. COVER UPRIGHT.

froth' is sometimes necessary in order to get a high-grade concentrate. Clean tailings generally mean only medium-grade concentrates due to entrainment of gangue, in the removal of all the mineral.

The stuffing-box in the bottom will probably leak if not watched. However, this driving of the impellers from below, instead of from above, leaves the top of the machine free for the operator and is more convenient in every way. This is of importance in a laboratory-machine, and will excuse the use of a stuffing-box. In large-scale machines a stuffing-box underneath would not be tolerated, and the drive should be from above. We would also suggest a sheet-lead construction as being more easily built. A ¼-inch sheet-lead is sufficiently rigid to stand up well, while it is ductile enough to be worked readily into the desired shape. The joints are easily burned, and it is acid-proof.

THE HOOVER MACHINE, so-called, was designed after a

test machine described in the second edition of Hoover's book, being copied from one of Lyster's patents and has been much copied by people wishing to make flotation

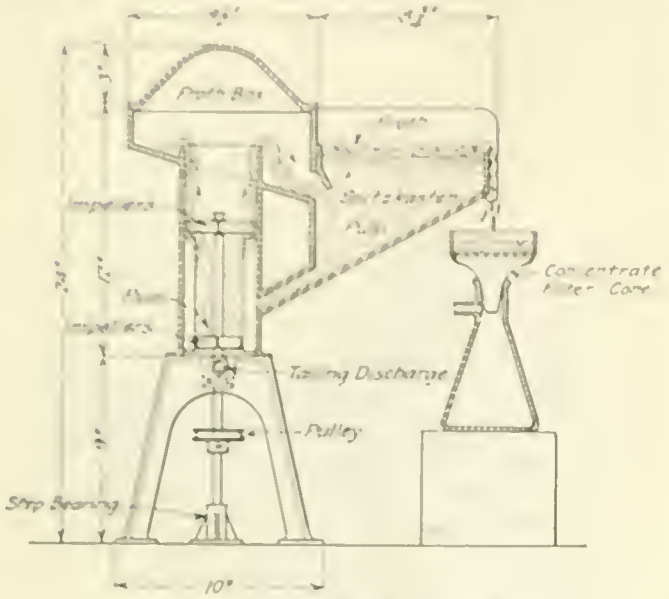

Fig. 7. THE JANNEY TEST MACHINE.

tests. An improvement over this construction was published by Ralph Smith[1] recently (see Fig. 10A), and a modified sketch of the same is shown in Fig. 10B, while

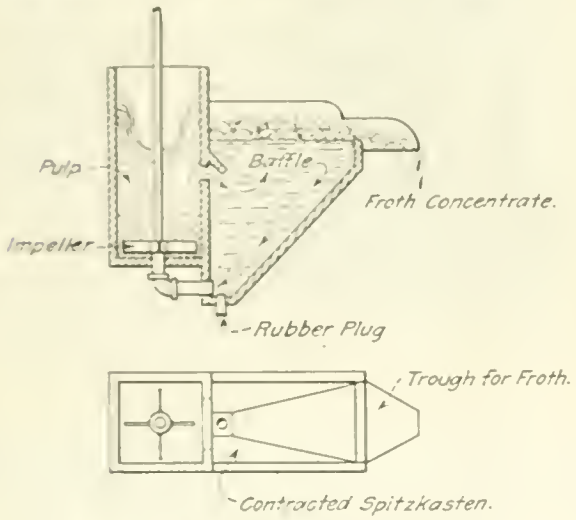

Fig. 10A. SKETCH OF THE LYSTER OR HOOVER MACHINE.

photographs of the machine used for a while in our laboratory are shown in Fig. 8 and 9. Either a variable-

[1]E. & M. J., Vol. C, page 395 (1915).

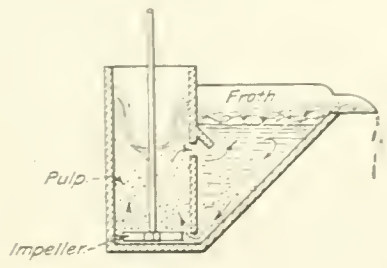

Fig. 10B. ANOTHER FORM OF HOOVER MACHINE.

speed motor is belted to the pulley that drives the stirring mechanism, or a pair of cone pulleys on a constant speed motor is used. This construction has been popular because it can be made of wood, at small expense. The Janney machine will cost about $100, while the Hoover machine can be built for a small fraction of that amount. Mr. Hoover's original drawing does not show the spitzkasten drawn to a point, as only the front

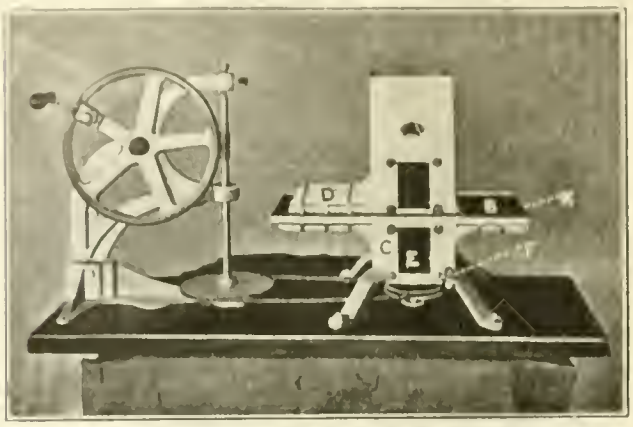

Fig. 11. THE SLIDE MACHINE.

side was beveled. Our sketch shows both sides beveled. This is desirable, as it eliminates space in which fine sand can settle, and tends to minimize the amount of

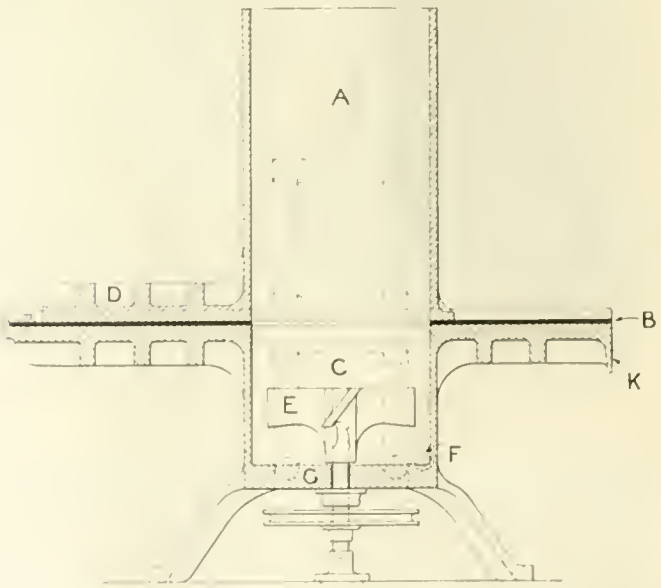

Fig. 12. THE SLIDE MACHINE.

pulp lying inactive in the spitzkasten. In the agitation-compartment the pulp is swirled into the corners, where it is well mixed with air; hence the baffles sketched in the Janney machine are unnecessary. One objection, however, is that unless the agitation-compartment is very tall the pulp being swirled into the corners has a tendency to splash out, and a lid similar to the one on the Janney machine is desirable. However, it is difficult to attach one because the stirrer-shafting is in the way. The operation of this machine is practically the same as that of the Janney, except that without glass sides on

the spitzkasten it is hard to get as clean a froth. A charge of 1000 to 2000 grams is necessary in this machine.

The Slide Machine, as shown in Fig. 11 and 12, was designed by Hoover and perfected by many others. In recent practice it is motor-driven. A number of these machines were given by James M. Hyde to various universities in this country. Many people favor this apparatus for the reason that they have had little opportunity to use any other design. In this machine the agitator is driven from below through a stuffing-box, as in the Janney, with the consequent freedom of the top of the machine for the convenience of the operator. The top half of the machine is so constructed that it can be slid to one side, cutting off the froth formed in the agitation from the gangue, which is allowed to settle. The operation consists in agitating with oil and other reagents, then a period of quiet during which the froth collects at the top while the gangue sinks. Two windows in the side enable the observer to see when the gangue has subsided sufficiently to allow the top half to be slid along the rubber gasket, cutting off the froth from the remainder of the pulp. The time necessary for the settling of the gangue is sufficient for much of the gangue to separate from the froth, leaving only clean sulphides in the froth. This element of the machine has made it of some value in testing flotation oils, but in a weak froth much of the sulphide mineral also settles out and is lost, so that the test results with this machine often show unnecessarily low extractions and a high grade of concentrate. On the other hand, when conditions are adjusted to give a froth persistent enough to hold all the sulphide mineral considerable gangue is entrained in the stiff froth. Further, after skimming one froth we find it necessary to add more water and start the machine again to make more froth. It is hard to make the slide machine give a high extraction with only one agitation. The intermittent character of such work and the time necessary to wait while settling are disadvantages that make the Janney or the Hoover machines of greater utility, in our opinion. The parts are of cast aluminum with a rubber gasket between. A charge of 500 to 1000 grams of ore is used.

Drilling in Narrow Stopes

By P. B. McDonald

THE staff of the North Star Mines Co. at Grass Valley, California, has for years given an unusual amount of attention to the subject of rock drills and drilling. As in other departments of their mining and milling, they have been keenly on the alert for improvements and have not hesitated to risk a trial of new or labor-saving devices in the hope of achieving economy in their operations. This general policy of attempting to lower costs by an added refinement or a new mechanical contrivance does not always work out as figured on paper. "In fact," said one of the staff, "what appears in advance likely to be a saving frequently proves a loss, and the reverse; we have made numerous mistakes, but, on the other hand, we have made savings much greater than the occasional losses."

So important is the matter of rock-drilling at the North Star, on account of the hardness of the ore and the narrowness of the stopes, that the expense of drilling has represented fully one-third of the cost of delivering ore to the mill. This fact has made it worth while to pay considerable attention to rock-drilling in its various phases; 70 or 80 rock-drills are in commission at the mine and over 18,000 drill-shifts are worked per year. It is obvious that an increase in efficiency of only one 4½-ft. hole per drill per shift will count up to appreciable proportions in twelve months, particularly when it is remembered that 25 or 30 ft. per shift is all that is possible for one machine to drill in this hard rock.

One of the admirable features of the rock-drilling methods at this mine is the system for recording results and repairs of the individual machines. The underground time-keepers make a daily report of the hours worked by each drill in much the same manner as they keep the time of the men. Thus if a drill is not doing good work, through some mechanical defect or lack of air, the fact is at once apparent on the tally sheets conveniently kept in the foremen's change-room at surface, where the accessibility of such records spread out on a table makes them doubly valuable during the frequent discussions of the foremen and superintendent between shifts as to what is taking place underground. A newly-repaired drill sent underground may lie around there a week or two before being used, after which it might break down immediately; records of all such occurrences are valuable to the superintendent and foremen. An important part of the record is the card system kept in the repair shop, where each rock-drill in the mine has a small card recording its repairs, an example of which is shown in Fig. 1. By these various records kept for each drill, it is possible to compare the different varieties in use and to see that each machine is maintained in perfect condition.

FIG. 2.

In the company's office is a card system for recording monthly data about the drills, in which the daily records from the mine are conveniently summarized. Each individual rock-drill is tabulated, as in Fig. 2. Details of the different varieties and makes of drills in use at the mine are summarized by months, as in Fig. 3. The yearly summary is tabulated, as in Fig. 4..

Previous to my visit to Grass Valley, I had heard more or less about the Paynter rock-drill tester as devised and patented by W. D. Paynter at the North Star mine, but I had supposed that the machine was merely a nice refinement for making sure that the rock-drill manufacturers did not sell an imperfect drill to the company. As a matter of fact the tester is much more than that; it has a broad field of usefulness. Something can be judged of its merit when it is stated that Mr. Paynter went to Michigan last summer to install one in the shop of the Copper Range Consolidated, that the Anaconda

company has put one in at Butte, the Copper Queen at Bisbee, and the Sullivan Machinery Co. recently ordered one for its factory. The tester was described in the Mining and Scientific Press of August 2, 1913. Briefly, it is an apparatus for determining quickly and accurately the number of blows struck per minute by any rock-drill and the foot-pounds of energy per blow. The essence of the usefulness of such a machine lies in the little-appreciated fact that for any particular variety of rock to be drilled, there is a strength of blow exactly suited to give the fastest and most satisfactory results. To illustrate, practice has shown at the North Star that a rock-drill striking a blow of 45 foot-pounds, with an air-pressure of 90 to 95 lb., is best suited to the rock in that mine. On one occasion two rival rock-drill representatives chanced to arrive at the mine simultaneously. Types of their respective drills were tested on the Paynter machine, which showed that one drill struck a

Fig. 4.

tremendously hard blow of 80 foot-pounds, while the other struck a much weaker blow, there being only a minor difference in the number of blows per minute. Naturally the man with the hard-hitting machine considered that his drill would do the better work underground; however, the mine-staff predicted that such would not be the case. The two drills were taken in the mine, where the weaker-hitting machine, even in the unusually hard rock of the district, drilled more footage in less time than its competitor. But that is not all. A similar test of the two drills was then made in the Empire mine, where the management favors an air-pressure of 70 to 75 lb. Here the harder-hitting machine, as would be expected, showed to advantage by reason of the lower pressure.

It is not difficult to see that in a soft sticky rock, such as schist or some varieties of slate, a hard-hitting drill will only tend to bury its bit in the ground, where it will stick and stop. Again, in a very hard brittle rock a too-powerful blow may only succeed in crystallizing and breaking the drill-steel. On the other hand, a machine striking too weak a blow will not cut so much ground as one striking a blow of just the proper strength. However, the proper strength of blow and the right number per minute will vary widely in different varieties of rock. The point is to determine what strength of blow is suited to the rock in any particular mine; to pick out a type of rock-drill that approximates that figure, adjust the blow to the exact strength by varying the valve a little; and then to keep all the rock-drills in the mine repaired and running at that strength of blow by occasional tests and adjustments. At the North Star mine an increase in the strength of blow was found to increase the speed of drilling up to a blow of 45 foot-pounds, after which any increase in the strength of blow decreased the drilling speed until 55 foot-pounds was reached, when it tended to increase at an insignificant rate. This was clearly shown in a curve plotted by Robert H. Bedford and William Hague, as given in a paper to the American Institute of Mining Engineers at Salt Lake City in August 1914.

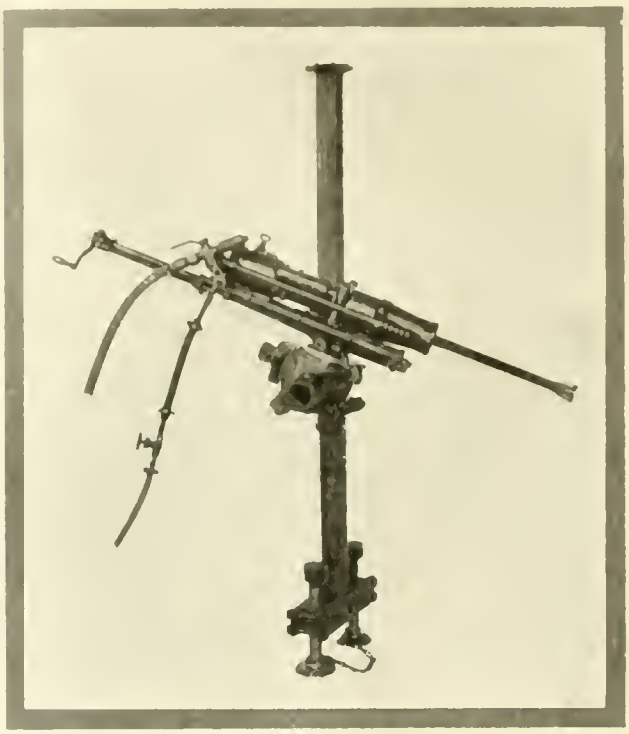
The Paynter tester gives a graph or card of the blows struck (usually taken for a period of 5 seconds) that can be interpreted quite as elaborately as a steam-card from an engine. Practice gained in the interpretation of these graphs enables the repair-man to tell which part of the drill is deficient, whether the lubricating oil is so thick that it is retarding the blow (as sometimes happens in a machine of tight-fitting parts), and a variety of minor details concerning the operation of the valve, hammer, piston, and other parts. In these cards (two of which were shown in the Mining and Scientific Press of July 3, 1915) the straight vertical line running up to the point represents the striking blow of the drill, that is 'the punch,' while the back stroke or 'recovery' is indicated by the wavering line to the next blow.

Another phase of the drilling practice at the North Star is the close attention paid to getting full-pressure air to each rock-drill underground. E. M. Weston has pointed out that on the Rand many of the mines have air-pipes, supplying drills at working-faces, that are so small that the air-pressure is cut down to an inefficient force. It is a common fault at many mines in this country to have too many drills on one small pipe, diminishing the pressure of air to insignificant strength. At the North Star power-house, the air is compressed to 105 lb., insuring a pressure of at least 90 lb. at the drills underground, which is in line with the modern

tendency to recognize the superiority of a high pressure of air for efficient drilling, just as dynamite of higher grade than formerly is becoming popular in mining. Frequent tests are made in the North Star mine underground by an air-gauge to determine if the air-pressure is up to standard in all stopes and drifts. It has been found that reports by the miners of unusually hard ground encountered, or poor work done by a certain drill, may be due to insufficient air pressure caused by careless piping. It is important that every miner and every drill (both of them expensive items on a cost sheet) shall have air pressure that will enable them to work to the best possible advantage. At this mine the air is taken down the vertical shaft by a 6-in. main from which reductions are made to the stopes until inch pipes each supply two drills.

I found at the North Star mine that Leyner and Waugh drills were the best liked. The old J. George Leyner No. 8 drill (which is not now manufactured) has given good service because it strikes a blow of just the right strength for this particular mine, 45 foot-pounds, and is a fast and satisfactory driller, in spite of its high cost for repairs. In competition with the Leyners there were being tried several of the new Dreadnaught drills of the Denver Rock Drill Co., which were apparently attracting favorable attention. I was told that the first Dreadnaught tested did not seem to strike a blow of sufficient force, but that this was now thought to have been due to the using of a too heavy lubricating oil on the new parts; with a lighter oil the drill had constantly improved its blow. As is more or less well known, the strength of blow depends a good deal on the air-cushioning (in the cylinder) that becomes necessary in order to attain a high number of blows per minute. Other things being equal, the machine striking a high number of blows, say 2000 per minute, will be expected to hit a lighter blow than a machine that strikes 1200 blows and cushions less. The Dreadnaught is a mounted hammer-water drill that differs from the Leyner-Ingersoll No. 18 in being a little lighter in weight and in being valveless. The valveless feature makes for simplicity and lessens repairs: the main objection to the valveless drill has been the difficulty of replacing worn parts, but with the increasing use of improved steel for such parts this objection may be much lessened. It is not unlikely that for drilling in flat stopes, such as in the North Star, where the dip is 23°, some such mounted machine as the Leyner or Dreadnaught will ultimately replace stoper drills. The latter are dusty as well as being not particularly suited to flat holes; thus the Calumet & Hecla, with a dip of 38°, has favored mounted Leyners for raising and stoping rather than the typical 'stopers.' At the North Star a number of Waugh stopers, both the new valveless types and the old 12-A type are in use. There are also a number of baby or 'chippy' Leyners, the light-weight Leyner-Ingersoll No. 26. Although this little machine does not strike so heavy a blow as might be wished, it is popular because of its handiness.

Incidentally I may mention that at the adjacent Empire mine, I found the Leyner-Ingersoll No. 18 and the Ingersoll Rand 10C 21 stoper to be the standard drills. The Empire is generally spoken of as being somewhat more conservative in the trying of new machinery than is the case at the North Star. Throughout the district I did not notice any new style drill-bits such as the Carr or H bits, but the old four point cross bit appears to remain in favor. There is no particular tendency to drill longer holes in stoping, as is so marked a policy in the wide stopes of the Lake Superior copper mines, for the



THE DREADNAUGHT DRILL. NOTE THE ABSENCE OF A VALVE CHEST.

reason that the stoping-width is so narrow (3 to 5 ft.) that the holes are drilled only 4½ ft. deep.

While I was at the North Star, Mr. Bedford showed me how they intended to draw one end of the water-tubes, after heating them, in order to reduce the diameter of the inch or two of length that protrudes into the hollow drill-steel. As is well known, there is some trouble from the water-tube of a water-drill becoming caught in the drill-steel and getting its end twisted off, causing much inconvenience in buying and replacing tubes. Considerable difficulty has been experienced at the North Star in reaming out the hole in hollow steel by hand after the sharpening has closed it; a modification of a machine in use at the Copper Queen mines at Bisbee is to be adopted, but using water pressure instead of air and oil cylinders, to ream the holes.

To a miner used to wide stopes the 2 or 3-ft. stopes of the Grass Valley district would appear extraordinarily diminutive and the little colums for mounting the drills would look ludicrous in stature; but the extraction of such a narrow vein of such hard ore from rock that holds it 'back' so that (as the Cornishmen say) "it's like pulling it out by the roots of the hair." is a problem of no mean proportions.

ON THE COLORADO RIVER.

ON THE ROAD TO THE MINES.

Oatman, Arizona—A Prohibition Camp

By Frank H. Probert

"HIT the golden trail to Oatman." "The golden hub of Mohave county's wheel of fortune." Let us hope that this joyous dithyrambic will not give place to a dirge of disappointment; let us hope that when the slag of excitement is cleared from this melting pot of men, money, and mines that a golden yield will result. Here's success to the prohibition camp of Oatman, the first of its kind in the Golden West!

The regular route is by way of Needles, California, on the Santa Fe railroad, where every train discharges many people bent on visiting Oatman, but the muddy Colorado river has to be forded on scows propelled by Indians and a fussy little motor-boat. On the Arizona side a score or more of automobiles are waiting to carry the crowd over one or other of the desert roads that lead to Oatman, 21 miles to the northeast. It is proposed to build a bridge across the river at Needles for the accommodation of traffic and there are recurrent rumors of a railroad from Topoc following the route of the dismantled narrow-gauge road built to the Vivian mine and so to the new camp. Most of the freight and many passengers reach Oatman through Kingman, 27 miles north, but the mountain grades are steeper and the road very dusty.

Leaving Needles and the broad expanse of river-bottom, the topography changes abruptly into a rough rock-ribbed section, characterized by the ruggedness of detail rather than by the broader features of mountain uplift. It is a district of igneous rocks and successive lava flows, the result of intermittent vulcanism. Gray crags of andesite, resistant ribs of paler rhyolite, a network of silicified vein outcrops, and on the higher elevations castellated buttes of tuff, the remnants of the mantle that covered and closed the Tertiary period, are con-

A STOCK-EXCHANGE.

A STREET SCENE.

spicuous features of the landscape. There is no running water, no vegetation other than the sage and cactus, the rocks are burnished by the attrition of hot sand, the softer part of the rock-mass has weathered, crumbled, and been removed, leaving the bare skeleton of the vein system to bleach in the blazing sun.

Passing Boundary Cone at the western end of the Black range, which guards the gate to this new treasury-vault, there are signs of activity, interest, expectancy, work, hope, and effort. Several townsites have been surveyed, and Old Trails, Ryan Addition, City of Carter, Mazona, Oatman, and others in the making, attract the visitor with promises of water, electric light, telephone, telegraph, good roads, reasonable rents, terms to suit tenants, and so forth.

The automobile stops at the Oasis café, the biggest little gold mine in the district, where the pay-streak is always rich and the bullion ready minted. A busy scene is presented, for this is the heart of Oatman, the end of the trail, a meeting-place for everybody. I counted 58 cars within a stone's throw of the Oasis at the noon-hour. The prospector's faithful friend, the burro, is no more; his place has been taken by the equally reliable and faster Ford car.

The Oasis café is the best place to feed, although the Mojave Eats, and the Mulligan, or 'Mad House,' as it has been dubbed, are well patronized, judging by the bread-line outside at 5 o'clock every evening.

Oatman is a typical boom camp of mushroom growth; houses hastily thrown together, lean-tos of all descriptions, stores, banks, booths—but no saloons. Arizona went dry on January 1, 1915. This subject of prohibition must not be dismissed without comment. Its effect on the standard of work, the *moral** of the community, and the deterrent influence it has against vicious practices is most noticeable. The saloons of former days, the bars, foot-rails, display of glassware, white-vested bartenders—all these outward signs remain; and the tendencies, appetites, and habits of mining men of all classes ring true to bygone days, but thirsts are quenched and success toasted with grape-juice high-balls, or malted milk. The result is obvious: the town is orderly, conversation is clean, competition keen, money is saved, a harmless game of pool or billiards serves as recreation after a full day in the field, and the street is deserted before 10 o'clock at night. I am informed that fully 30% of the monthly pay-roll is invested in local mining-stocks, or put into the ground prospecting. There is a contagious, clean, healthy atmosphere.

Accommodations for the visiting hordes are not of the best, but are improving. Prospect tunnels and the dry arroyos near town are eagerly sought by the wise ones who have brought their blankets. The Oatman Hotel sleeps two and three men in a room, and lucky is he who can find private quarters.

What a motley mixture of humanity, what types are foregathered here! Bankers, brokers, engineers, agents, those of brawn and those of brain, promoters intent on selling something they haven't got to someone who doesn't want it, newspaper men, State senators, pseudo-politicians, horny-handed miners, yellow-legged experts, all sorts and conditions of men, all there for one purpose, all buoyed by the same hope. Subconsciously one appreciates the motto of the golden eagle: 'In God we Trust.' Everybody of note is addressed by his first name, as uncle John, Frank, Ralph, Lew, Tom, Dick, or Harry, and it is a sign of professional standing if your name is misspelled in the local papers. The number of qualifying adjectives, such as safe, conservative, or prominent, before a name indicates the degree of esteem in which the visitor is held by the enterprising reporter. But good nature prevails and Diamondfield Jack has as many friends as other noted characters.

Business is brisk in Oatman. Transactions involving thousands of dollars and hundreds of thousands of shares are discussed and arranged so airily and so easily and with such dispatch that it is bewildering. The new arrival is button-holed, taken up over the outcrop of the Olla Oatman where the wonders of the world are pointed out to him; here is the vein, there is the United Eastern, the ore lies so deep, this group of claims has a better and bigger showing, all you have to do is to go down, first in your pockets, then in the ground. Groups of claims change hands every day, on paper. Short-lived options, usually five days, are the thing, for and in consideration of x dollars and 1000 x shares of stock. Possibly the claims have not been recorded, maybe the location work has not been done; what matters? Was not the United Western company organized on the Oofty Goofty, Oofty Goofty No. 1, and Oofty Goofty No. 2, three claims a mile or more away from the main group on which the present work is being done.

Already there are over 50 companies organized to explore the district, within a radius of four miles of Oatman. Nearly all have a capitalization of a million shares variously quoted on the Oatman Investment Co.'s board from 10 cents up. A few are inactive, most of them range between 20 and 50 cents, while the United Eastern heads the list at quotations of $4.50, one hundred times its selling price of a year ago, and fully justified by the value of ore developed. There are many 'wild-cats,' but who has the courage to differentiate between this prospect and that? Could any excuse for an outcrop be less attractive than that of the United Eastern, or any surface showing more inviting than the Olla Oatman, below which little or no ore has been found?

No subject is of greater interest or more engrossing than the psychology of mining, the analysis of the mental attitude of the speculator; and surely there is no better field in which to study it than Oatman. The veins outcrop, either as prominent silicified ribs in the softer andesites or as shallow depressions in the quartz-porphyry or rhyolite, all showing more or less brecciated rock fragments cemented by calcite or quartz. There are many of them, trending generally to the north-west. The ore occurs as a series of lenses pinching vertically

*[This is not a typographical error. The word in this sense is commonly spelled *morale*, which is wrong.—Editor.]

and horizontally within the vein-filling; owing to the re-opening of fractures, oxidation and leaching are advanced. Gold is seldom found near the surface in paying quantity. The rich ore-shoot of the United Eastern apexed 300 ft. below the surface: the first ore mined in the Tom Reed was even deeper, hence it is axiomatic among owners of claims and promoters of companies that a shaft must be sunk 300 to 500 ft. before cross-cutting to the vein or driving along it. The stock market responds to these conditions; interest increases as the prescribed depth is attained, and the volume of business is directly proportional to distance from surface. Failure to find ore is not discouraging as long as the vein is there. After the first shock of disappointment, speculation is renewed as the drift advances; even 60% Hercules powder cannot shatter the assurance of the manipulators of stock. If the pay-shoot is not on this level, then of a certainty it must be below. There is always the dominating influence of hope, the insatiable desire to gamble.

THE NOON HOUR AT OATMAN.

Already five or six companies have taken their place on the anxious seat of expectancy and suspense; the United Western is cross-cutting to a vein at the 507-ft. level; the Big Jim at the 400; the Oatman Gold, Black Range, and Telluride are pushing lateral work. Success in any one of these will fan the flame of excitement into the wildest enthusiasm and the whole list will respond. Even the most sanguine of optimists does not expect that all the properties will strike a bonanza, but unquestionably other rich shoots will be exposed by the systematic development in progress throughout the district. That pay-ore extends to considerable depths is evidenced by the Tom Reed and Gold Road mines, where ore of good milling grade is being stoped on the 1075 and 1100-ft. levels, respectively. The Pioneer, Orion, and Vivian properties were opened below the 400-ft. level before the present boom started. Further work is contemplated.

The district is not new; it has been prospected for 40 years, and the Gold Road and Tom Reed properties long ago entered the ranks of dividend-payers. The question naturally arises, why has it languished so long? Why, in a region of prominent outcrops, has there been so little actual mining development? Is this awakening due to a better understanding of geological problems, to improvements in mining and metallurgical practice, to the chance discovery of another bonanza, or is there a plethora of American money seeking avenues of investment? Widely different views are held on this subject, but the cold fact remains that Oatman is to be thoroughly and systematically explored until its hidden riches are uncovered. History will repeat itself, and when the books are finally balanced it may be found that for every dollar taken out of the ground, three or four have been expended.

The foregoing paragraphs are of human interest. Such reflections are indelibly impressed on the mind and memory of the nomadic engineer. But there are matters of technical interest, ideas of the genesis, occurrence, mining, and treatment of the ores to be discussed, and still many intricate problems to be solved.

Nearly all of the precious-metal deposits of the Western States have been found in broad metallographic province of Tertiary lavas, extending from northern Nevada to southern Mexico. Attempts to show that commercial mineralization is confined to one or other of the differentiated flows have led to much controversy and delayed search in proscribed areas. Theories however beautiful are often killed by facts, however ugly. The highly commendable work of J. E. Spurr at Tonopah in 1904 was challenged by J. A. Burgess in the light of later development, although a revision of data led to no serious change of opinion. The discussion of the dacites at Waihi, in New Zealand (Tertiary lavas), is another case in point.† At Tonopah the earlier andesite has been the most productive. At Goldfield the dacite carries the ore, although rich shoots at the Kendall and Sandstorm mines occur in the old effusive rhyolite, while gold prospects were found north of Diamondfield in the younger andesites. The deposits of Bullfrog are in rhyolite with quartz and calcite vein-filling: the Manhattan ore is

†M. & S. P., November 13, 1915, page 729.

associated with intrusive rhyolite, and at Searchlight the orebodies of the Quartette mine are related to the andesite-porphyry. At Randsburg, California, older rhyolites carry the ore. In Mexico other examples of the distribution of gold and silver in one or other of the earlier Tertiary flows could be given. From the available data, it is evident that in different localities one member of the series of lavas has played the major part in the formation of primary ore. This may have been enriched, either by addition of mineral from later intrusives, or by concentration due to processes of oxidation and leaching made active by structural features induced by the orogenic disturbances of later times.

No careful geologic work has been done at Oatman. A correct diagnosis of the rock sequence and mineralizing agencies would be of inestimable value. In Bulletin 397 of the U. S. Geological Survey, F. C. Schrader gives the results of his reconnaissance in somewhat ambiguous phraseology, which fortunately was elucidated by Howland Bancroft in the Mining and Scientific Press of July 3, 1915. W. H. Weed is non-committal in the statement that the dikes (meaning intrusives) have been fissured and mineralized by vein-forming agencies. E. W. Brooks is more positive and limits the area of commercial mineralization to the newer andesite, thus confirming Mr. Schrader, but he refers to it as a flow, being "poured out upon the older andesite." My own hurried observations suggest the importance of studying:

1. The true nature of the younger andesite.
2. The influence of later volcanic disturbances on vein-structure.
3. The relationship between value of ore and replacement of calcspar by secondary quartz.
4. The influence of oxidation on the vertical distribution of ore.
5. The inference that can be drawn as to the nature of deep-seated ore from the character of that now developed.

Seriatim, I am of the opinion that the newer andesite was both intrusive and extrusive, that dikes and sills of this chloritic andesite occur in the older flow, and that the possibilities of mineralization of vein-fissures is dependent upon this association. Veins in both the older and newer andesites may therefore be productive to a considerable depth.

Rhyolite dikes and quartz-porphyry intrusions have played an important part in shattering the rock-mass, re-opening spar-filled fissures, causing a brecciation not only of the gangue but of the enclosing wall-rocks, and admitting of active oxidation to great depth, with probable concentration of precious metals at well-defined horizons. Strike-faulting is very noticeable within the vein and probably determined the lenticular form of the ore-shoots. Groovings and striations would indicate both horizontal and vertical movements that may explain the tendency of shoots to pitch, or rake, to the north. The acid intrusives may, too, be the source of the silicious waters that have re-cemented the brecciated material in the veins.

There is a pronounced relationship between high-grade ore and secondary silica; or, conversely, unaltered calcspar, the original vein-filling, is generally low-grade, if not barren. This condition can be studied well in the United Eastern mine, where frequent cross-cuts show the erratic distribution of the rich ore. The gold is very finely divided and rarely noticeable to the naked eye. It is always associated with a dull waxy-green variety of quartz of resinous lustre, resembling bees-wax. Under a hand lens the quartz is seen to replace the calcite. Banded structure is not common and veinlets of secondary silica appear penetrating the crystal mass of the spar. As accessory minerals, fluorspar is plentiful in certain localities, as on the Times group, while limonite and manganese oxides are well distributed throughout the district.

The subject of oxidation is important. None of the mines is wet and ground-water level has not been established in any workings on the vein system. The re-opening of fissures and strike-faulting indicated by the included angular fragments of wall-rock, by crushed vein-filling, and by persistent striated polished walls within the vein itself, rendered conditions favorable for the percolation of oxygenated waters to great depth, with the attendant possibilities of enrichment. Manganese is a common constituent of the vein-filling, and, as is now generally recognized, plays a prominent part in the precipitation of gold from migrating solutions. At Oatman I found many examples of free gold in intimate association with blebs of limonite and manganese oxide. This, in my opinion, is not residual gold, it was not left to enrich the specimen by the removal of other more readily soluble minerals, but was precipitated when the descending waters ceased to be acid in character and when ferric and manganic salts predominated. The porosity of the veins at Oatman, the presence of manganese, the advanced oxidation are all contributory causes to the localization of the ore-shoots some distance below the surface.

As a corollary to the above, it is to be inferred that sulphides will be found below the zone of oxidation. Pannings of discarded assay-pulps first caused me to look for sulphides in the more compact portions of the vein underground. Sulphides are not uncommon and will be found in increasing quantity on the lower levels. At the horizon where oxidizing conditions ceased, gold, limonite, and manganese oxides were deposited, and still deeper the primary sulphides may be anticipated.

The chief impression I have, as a result of my visit to this promising district, is that careful, competent, searching study of the geology of the district will prevent the useless expenditure of money in many directions, and lead to intelligent development in others.

The excitement caused by developments at Oatman is spreading to the old Cerbat and Chloride mining districts. The Golconda zinc mine, the property of the Union Basin Mining Co., after proving the continuity of the ore to the 900-ft. level, is building a 200-ton flotation plant, which should be running early in 1916.

The prospects of Mohave county are promising.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

DENVER, COLORADO

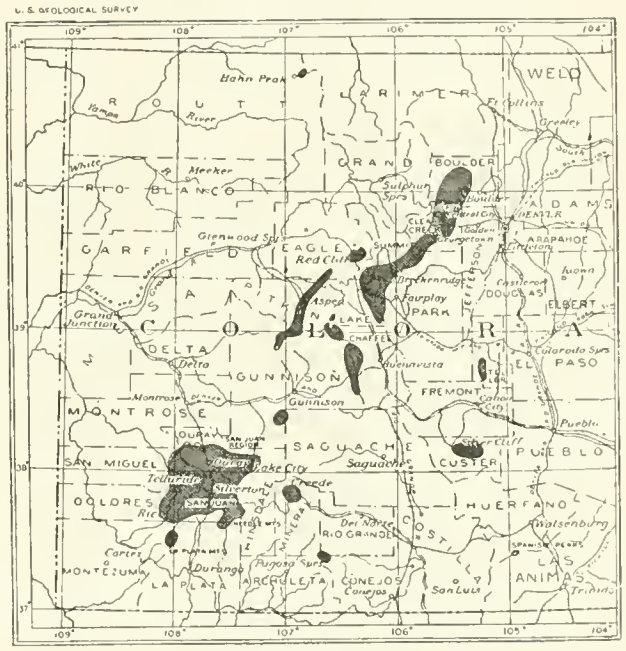
Tungsten in the San Juan.—The Down Town Area of Leadville.—A 'Dry' State, and Probable Effects.—New Roads.

A recent letter mentioned the deposits of tungsten on or near Cement creek in the San Juan mountains, which have been known for a long time. The increasing price of tungsten has finally resulted in the active development of several veins known to contain tungsten. The Yukon mill, which is on Cement creek a mile or so below the Gold King plant, has been acquired by the tungsten operators, and is now producing concentrates.

With a few of the usual mishaps which attend any large enterprise, the unwatering of the Down Town mines at Leadville progresses steadily. The water is now down to about the 700-ft. level of the Penrose shaft. While some zinc ore has already been shipped from the drained area, results have been small so far. It always takes time to get large operations under way. The draining has made available a large and favorable area for prospecting, but uncovered only a few known orebodies. The known deposits are mostly in the 200 ft. yet to be unwatered. One of the interesting questions that may be solved by this enterprise is whether or not the famous Leadville ore-shoots extend for a considerable distance down toward the Arkansas. Judge Owers, well known in Leadville, assisted in putting down some diamond-drill holes many years ago, the results convincing him that as much or more ore lay on the dip below the Penrose shaft as above it. He acquired a large territory covering the supposed extension of these ore-shoots, and spent a large part of the latter days of his life endeavoring to finance the project of sinking a new shaft to cut the ore horizon on the dip, some distance below the Penrose. Unfortunately the drilling records were not sufficiently conclusive to warrant such a large undertaking, and the project was never consummated. The pumping equipment now installed is far more efficient than the old plant, so it is reasonable to expect that an additional hundred feet or so will not deter the operators from following the ore down on the dip as long as prospects are good.

The Supreme Court of Colorado has decided that not even the home-rule cities of Colorado may dispense liquor after January 1, 1916. So the State will be dry as ashes. There is considerable difference of opinion as to the advisability of this drastic prohibltion law as regards the prosperity of the State as a whole. It is thought by many that it simply amounts to transferring the profits of the liquor trade from the hands of Colorado citizens to those of other States. It is pointed out that the consumption of liquor in prohibition territory, both in this State and in others, is nearly as great as in wet territory. The only difference being in the method of distribution. That the present good system of distribution, which includes such magnificent units as the Silver Dollar saloon, the Brown Palace bar, the six Colorado breweries, and other notable works of man, will be ruthlessly destroyed in favor of the mail-order house with headquarters outside the State. On the other hand, the roseate claims of the 'drys' are well known. Phoenix will miraculously arise from the ashes of legal destruction, and a large chunk of the millenium will burst forth upon Colorado like the life giving sunshine of spring after the clouds of winter. However diverse the opinions may be as to the effects of this law on the State as a whole, there is little difference of opinion as to its effect on the mining centres. The open saloon is an institution that most mining men cherish, but experience has shown that it is not good for us. While the mining towns 'religiously' voted wet, still every miner one meets is of the opinion that dry places will be a good thing. The mail-order route may not be as sociable as the bright lights, the brass rail, and the familiar "This one's on me, boys," but it is a whole lot better for the health. Less pneumonia, more sleep, less hurrah, more work—prosaic, uninteresting, but as long as it was forced on us we know it is going to be beneficial.

The extremely open winter weather has been a good thing



MAP OF COLORADO.

for the mining industry. Money has been tight, as every one knows, and many enterprises were without funds until late in the fall. If the winter snows had come early, an unusually large amount of surface work would have been suspended until spring. Take the single item of roads for instance: I feel sure that there were more miles of wagon-road built in Colorado's mountains during November and the first half of December this year, than in any similar period of its history. The new highway from Durango to Alamosa was finished late in November; the Bear Creek Canyon road was finished on December 13, and the Jarr Canyon road to Cripple Creek was completed about December 1.

The outlook at present is that next year will be one in which the high water run-off will be of short duration. It is the early snows that drift into the big banks and last until August. The spring snows, even though abundant, do not get packed down, and they go off with a rush in June. This condition is bad for the farmer, but favorable for the miner. It means open roads and trails and little water to pump. Some power-plants are feeling the lack of water, but then there is plenty of coal to burn and plenty of auxiliary steam plants available for the larger distributing agents.

FAIRBANKS, ALASKA

Roads to Tolovana, and Prospects of the New District—Fairbanks Last Season, and Prospects for Next—Scrapers—Lode Mines—Tungsten

Now that a good trail has been constructed to the Tolovana and Olnes, much travel and freighting has been done between Fairbanks and Livengood. Many criticisms of the trail have been made, as while the route is about the shortest possible, there are several high divides that make heavy hauls difficult. Many people advocate the Happy Creek route. Though at least 15 miles longer, it has no appreciable grades. H. H. Ross, territorial road overseer, is now engaged in cutting out a winter trail by way of that route with the aid of a Holt caterpillar-tractor, intending to do heavy hauling that way later. Good progress has been made so far, the men being at Lake Minto, and one lot of men has left Livengood to meet the others, to assist in the work. If a post-office is finally assigned to the new district, it will be designated Livengood by the Post-Office department, the original name of Brooks not being considered suitable. There is a Brooks in Alabama, and an improper abbreviation for Alaska would result in much confusion. However, commissioner and recorder Atwell was appointed as that officer for Brooks, and the radio-station is also known as Brooks. How the mix-up will be straightened out is yet to be seen. If the pay-streaks are as good as hoped for, however, the matter of names will be incidental.

No extensive prospecting was done last month, all the prospectors being busy arranging for the winter. From now on the 'dirt' will fly, and the camp be developed considerably during the next few months. That there is pay, and good pay on Livengood, has already been proved; but whether it is only in spots, or continuous, is yet to be determined. Pay has also been reported on the Mike Hess side, but no sluicing has been done there to prove this. The general feeling is one of quiet optimism, and it will take a lot of blank holes to discourage anybody.——Plans are already under way to remove the immense log-jam that blocks navigation to the mouth of Livengood creek, so that freight will be much cheaper by water next year than this, when portaging was necessary for the 500 tons of material that was shipped in that way.

The fact that gold production from Fairbanks placer mining in the past season was much greater than last has been a source of great satisfaction to everybody. Merchants report much better business for the fall than a year ago, and the extensive operations planned for next season should keep production up to the mark. Open-cuts on Cleary and Pedro creeks will be as extensive, while the usual amount of drift mining will be carried on on Fairbanks, Chatanika, and Ester creeks. The ground adjoining that on Ester, which gave a fortune to Short and Ray last season, will be worked this winter and next summer by Jack Leach, who has just as good pay in sight. The Al Hilty open-cut on Cleary will also yield well again, unless the option on the greater part of the creek is taken up, in which case production will be delayed till a dredge is erected. This option is held by delegate Wickersham and associates. If taken up, either the Murphy ditch will be completed from the head of Chatanika, and the creek hydraulicked or a dredge constructed. The Hilty ground yielded a large return this year, not only paying off considerable debt, but putting Hilty and Durand on their feet, if reports are authentic. The ground was worked with a large Bagley scraper and American scraping engine.

Hanot Bros. are to erect a much larger patented scraping rig on their Pedro ground. In this machine the scraper is attached rigidly to a carrier that travels on a trolley cable to boxes. As soon as the load is picked up, the slack is pulled out of the trolley cable, and the load is taken to the boxes, with more speed and much less power than is possible with either the slip scraper or Bagley scraper. Aside from the patented features, the rig is similar to the levee machine used on the Mississippi that was illustrated in the June, 1915, issue of *The World's Work*.

That the quartz properties on Fairbanks creek are gradually emerging from the prospecting to the production stage is shown by the three small steam plants now working there. McGillvray, Nars, and Handberry have recently installed a small hoist, and expect to make regular shipments to the custom mill farther down the hill. This property has long been idle, but the advent of a good custom plant has made operations much less of a gamble. Considerable ore of milling grade has been blocked out. Ott, McGowan, and Lyden have also erected a small steam plant on their lease, and are taking out ore for shipment to the Hellig mill. Their lease is on a portion of the Gus Hess ground, and adjoins the Mispah claim where Hess, Gels, and Thompson are now operating. While they have been working only a few months, the lessees are well satisfied with results. Hess and partners are also using a steam-hoist, and have been in good ore for some time. They should have a large shipment ready in a few weeks.

Gilmore and Stevens have bought out the last of the lessees on their ground, and are now operating on their own account. Their new five-stamp Allis-Chalmers mill has been started again, and should be kept working steadily from now on with proper management. The lessees extracted only a small part of the 6-ft. lode and could not keep the mill going full time, but the owners think the whole vein can be milled at a profit. Operations so far consist of windlassing from two shafts, but a power hoist will soon be necessary. At the Huddleston-Leyendecker property, in which Gilmore also holds an interest, the vein has been found down the hill from the shaft, and an adit is being driven. The shaft was lost last summer, due to heavy rains, and stoping too near to it and the surface. The adit shows 4 ft. of milling ore.

McCarty and Kellen are now cleaning out the old stopes of the Pioneer claim to get the $15 to $20 ore shot down as waste when this grade could not be treated at a profit.

Foss and Farvean have been getting some good ore lately from their lease at the McDonough property. The last 60 tons milled averaged over $30 per ton, and it is expected that the next shipment will net even better. The lessees use an Ingersoll-Rand stoper with steam, and while it is not always very comfortable to work with, it is better than hand-drilling. Lots of trouble was experienced at this property from water and swelling ground this fall, and practically the whole mine had to be re-timbered, the largest timbers obtainable being used. Everything is in good shape now, and the partners will probably be well repaid for their extra trouble and expense.

Crites and Feldman have had the misfortune lately to get drowned out of their shaft on the top of the hill. The shaft was being sunk for prospecting purposes before the main adit was driven that distance and the flow of water was considered too large to handle economically. A cross-cut adit will now be driven to cut the vein at a depth of 150 ft., and in case the grade continues, the main adit will be driven in from the mill-site.

The mortgage on the Newsboy mine has been foreclosed and the property will pass into private hands. Several calls were made for a stockholders' meeting to consider a plan whereby a foreclosure could be avoided, but as there was no quorum present, this had to be resorted to. At any rate, this property will probably pass into the active list sooner than under private ownership.

Encouraging reports come from the newly discovered scheelite deposit at the head of Gilmore creek, the shoot widening considerably and containing a high percentage of tungsten. Albert Johnson, the owner, is a prospector of wide experience, and says that the deposit has more promise of size and continuity than any he has seen. Placer scheelite has been seen ever since the creek was worked; this vein is probably one of the main sources of the mineral.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Chisana

Gold output of the Chisana district last season was between $100,000 and $150,000. About 50 men will winter there. More work is to be done during the winter than before. Several prospects are reported to be very promising.

Juneau

Twenty claims, two mill-sites and water-rights at Windham bay have been sold by G. Jensen and E. J. Dailey to the Alaska Bond & Development Co., H. H. Smith president, for $232,000. Work will commence in the spring.

During the first 13 days of December the Alaska Gastineau mill treated 51,659 tons of ore averaging $1.10 per ton; the tailing assayed 23 cents. By the end of 1915 it was hoped to have the heads up to $1.35 per ton. On No. 6 level of the mine 808 ft. has been driven east, with good ore in the face. The last 300 ft. averaged $5.36 per ton. The schist had not been entered on December 20. On No. 7 level the east drift was advanced 667 ft., the last 110 ft. assaying $4 per ton. All stopes are looking better. The Annex Creek power-plant is working.

On December 17 a snow-slide demolished the blacksmith-shop change-house, and dry-house at the Gold Belt mine. The damage is estimated at $2000. The crew in the adit are temporarily engaged at diamond-drilling.

Eugene Meyer, Jr., & Co. have issued a summary of a report of J. H. MacKenzie, consulting engineer of the Alaska Juneau Gold Mining Co., showing the progress being made in development and equipment of the plant. It says in part: "Practically all contracts have been let for mill and power-plant construction. Grading for power-plant is completed. Mill grading is more than 50% complete. Erection will commence early in the spring, and it is anticipated that the plant will be ready for operation on schedule time. The mill design is believed to embody every desirable known economic feature based upon the most recent experience in mill construction. The ore will move entirely by gravity through the various phases of treatment. Mill screens have been entirely eliminated, with consequent increase in capacity and reduction in milling costs. Ample wharfing facilities have been completed, making it possible to bring the largest ocean-going steamers within a stone's throw of the reduction-plant. There remains one additional warehouse to be erected. Compressors, blacksmith-shops, and general buildings all of ample size were completed before the beginning of the present enlarged program. The original plans for placing the property on an 8000-ton daily basis are going forward absolutely according to expectations and schedule, and there is every reason to believe that the final expenditures to complete the plant will not exceed the present cash resources of the company. It is expected that the plant will be in operation early in 1917."

ARIZONA

Cochise County

Prospectors in the Huachuca mountains are active at present. The area has produced a good deal of gold from placers. In Ash canyon a formation has been opened containing a rich but narrow vein. Several copper deposits are producing ore. Snow has fallen in the mountains recently.

Graham County

In Hooker canyon, on the opposite side of the Gila river from Geronimo, P. Morgan and Owens Bros. have found a wide deposit of gold-bearing decomposed porphyry, with some silver and copper. They reported this at Globe last week.

Greenlee County

The Detroit Copper Co. has 140 mining claims on which assessment work has to be done. Men were sent to do this, but they were driven out by the strikers. The company on December 18 filed a complaint with Judge Sawtell of the Federal court against the Western Federation of Miners, asking for an injunction restraining this body from interfering with the work mentioned. An order was issued accordingly. Governor Hunt refused to discuss the matter.

Mohave County

The latest and one of the most important reports from the Oatman district is that the Tom Reed and United Eastern mines are being sampled with a view to consolidation.

Drilling has been started at the Copperfield Porphyry Copper company's ground near Mineral Park. The shaft is 40 ft. deep. Fifteen per cent ore is to be shipped. There is talk of a 100-ton mill. Power can be secured at $12 per hp. month.

The Golconda Extension shaft has cut high-grade gold-silver stringers at 350 ft. The main orebody is considered to be near.

A new method of concentrating molybdenum ore has been devised by T. D. Walsh, who has been experimenting at the Leviathan mine.——The new mill of the American Molybdenum Co. is in commission.

A new road is being constructed into the tungsten area 12 miles east of Yucca. Forty men are employed.——A new road over Goldroad hill is to be built by the county at a cost of $33,800. This will cut down the heavy grades on the old road.

At 250 ft. in the Carter Mining & Milling Co.'s mine, 26 miles south-west of Kingman, a cross-cut has passed through 10 ft. of $30 ore.

At the Lazy Boy a two-drill compressor and machine-drills are at work. The shaft is down 60 ft. A 40-hp. gasoline hoist is to be installed at once.

The United Northern company is constructing a road one-half mile long, and grading for machinery. A two-compartment vertical shaft is to be sunk 500 feet.

The Oatman Amalgamated Gold Mines Co. has been organized by C. A. Jones of Los Angeles and J. T. Burns of Colorado Springs, Colo., for the exploration and development of approximately 400 acres of ground.

Extensive interest is being taken in the Cedar Valley, Union Pass, and Wallapai districts, where are a large number of prospects and properties in the development stages.

In the Aquarius mountains, 56 miles from Oatman, A. C. Parsons of San Francisco has purchased 13 claims, in which is said to be a commercial deposit of bismuth.

CALIFORNIA

The State Mining Bureau, under the direction of Fletcher Hamilton, state mineralogist, is preparing a new, general report on all of the mineral resources of California. Instead of delaying publication until the entire area of the State has been covered, the reports are being issued as advance chapters, by groups of adjacent counties, as soon as completed by the

field men. Competent geologists and mining engineers are engaged in the field gathering data, and it is expected in the next few months to complete this survey of the whole State. All mines, quarries, mineral springs, cement mills, and other plants handling mineral products are listed and described, including situation, equipment, extent of development, geological conditions, etc. The reports are well illustrated with photographs and drawings, and contain also tables of the mineral yield of the several counties, showing a wide diversity of products.

The following chapters have just been received from the printer, and are now ready for distribution at the prices indicated, which includes postage. They may be obtained from the main office of the State Mining Bureau, Ferry building, San Francisco, or the southern California branch office, at Room 208, Union League building, Los Angeles.

The chapter on Amador, Calaveras, and Tuolumne counties

MAP OF CALIFORNIA, SHOWING COUNTIES.

covers the central portion of the Mother Lode gold belt. This district is one of the oldest, and is still the most important quartz gold-producing section of the State. With photographs, charts, and index; the report contains 180 pages and the price is 50c., postpaid. The author is W. B. Fletcher, field assistant. There are three distinct lodes in Amador county, the principal being the Central or Mother Lode belt. The quartz veins of this formation occur in black slate, black slate and diabase, and amphibolite schist. From 1880 to 1913, inclusive, Amador County mines have yielded a total of $64,338,755, of which $62,511,953 was from gold. Fifty pages are devoted to interesting descriptions of the deposits and general development of asbestos, clay, coal, copper, gold (38 pages), lime, marble, and sandstone. Work at Jackson is being done to a depth of 4100 feet.

Notes on Calaveras county cover 78 pages. In 34 years the mineral output was $49,437,433, of which gold accounted for $39,920,552, and copper $8,233,314. The Mother Lode here displays the characteristics of large bodies of low and medium-grade ore, presenting mining propositions now attractive to conservative capital.

Tuolumne county (41 pages), had an output of $34,744,511 in 34 years, gold contributing $32,983,771, and limestone and marble over $1,200,000. Some well known mines are operated in this county. Readers of the Press will have noted the revival at Sonora of late.

The chapter on the 'north of the Bay' (San Francisco) group covers the counties of Colusa, Glenn, Lake, Marin, Napa, Solano, Sonoma, and Yolo. This district contains a greater number and variety of mineral springs than any other similar area in the United States. It has also been an important producer of quicksilver, and is notable for its yield of cement, crushed rock and other building materials. The report contains 208 pages and the price is 50c. postpaid. Walter W. Bradley is the author, who had an extensive area to cover to investigate the varied resources. The value of the mineral production of these counties is as follows: Colusa, (from 1875), $2,621,123, sandstone amounting to $1,440,998, and mineral water, $881,258; Glenn (from 1890), $244,876, building materials predominating; Lake (from 1873), 247,877 flasks of quicksilver worth $9,404,501, 6,117,457 gal. of mineral water, $2,080,715, and $501,236 of borax; Marin (from 1888), $3,869,799, brick and stone making over $3,700,000; Napa (from 1862), $24,648,719, of which $14,898,054 is from 334,063 flasks of mercury, and $1,779,999 from mineral water; Solano (from 1873), $17,205,665, mostly building materials; Sonoma (from 1873), $7,662,966, quicksilver contributing $2,533,228 and stone $4,277,886; while the mineral resources of Yolo county are now being developed. Copiously illustrated deposits and plants add greatly to the value of this report.

The chapter on Del Norte, Humboldt, and Mendocino covers the three northernmost coast counties. There are important mineral resources in this area, most of them as yet undeveloped owing to lack of transportation facilities. The completion of the Northwestern Pacific railroad to Eureka, and the line now reported under construction from Grant's Pass, Oregon, to Crescent City, will result in increased development of all industries in this district. It is also one of the most important lumbering areas of the State. The report is of 60 pages, and the price is 25c. postpaid. F. L. Lowell is the author, who commences with a brief geologic description of the region. The black sands of this part of the State are frequently discussed among mining men, and under Del Norte and Humboldt counties the author gives some notes on the subject. Chrome iron occurs in several places. The Horse Mountain copper deposits, before the investing public some time ago, are described; so are the placer operations, oil occurrence, magnesite, and manganese.

The chapter on the San Joaquin Valley district covers the counties of Fresno, Kern, Kings, Madera, Mariposa, Merced, San Joaquin, and Stanislaus. While this is one of the most important agricultural sections of California, it also has large and valuable mineral resources, including the Kern County and Coalinga oil fields, and the famous Raymond granite quarries. The report covers 220 pages, the price of which is 50c. postpaid. The authors are Walter W. Bradley, G. Chester Brown, F. L. Lowell, and R. P. McLaughlin. Fresno county has a mineral output of $66,294,637, petroleum accounting for $62,130,959, copper $1,063,957, and stone $1,167,433. As the oil industry was recently covered in Bulletin 69 of the Mining Bureau, only brief mention is made of the industry in this and Kern county, the latter having produced $131,441,710 out of a total of $159,176,373 of all minerals. Interesting reviews are given on the power schemes, quarries, quicksilver deposits, antimony, the Nimaret iron deposit (by F. B. Weeks), in Madera county, gold mining in Mariposa county, dredging in Merced county, and gas wells in San Joaquin county.

The chapter on Shasta, Siskiyou, and Trinity counties covers an area in which is located the State's largest copper and silver-producing area, also the largest yielding hydraulic gold mines of the present day. The western part of this area in particular has great possibilities from a mineral standpoint, but as yet only slightly developed on account of meager trans-

portation facilities. The report is of 192 pages, the price being 50c. postpaid. G. Chester Brown is the author. The mineral yield of these areas is as follows: Shasta (from 1880), $102,921,076, of which $66,603,109 is copper, and $24,528,938 gold; Siskiyou (from 1894), about $15,000,000, mostly gold; and Trinity, $150,000,000, mostly gold. Shasta county is busy at present on account of the demand for copper, while the zinc output is increasing at a great rate; the copper belt is fully described. Some of the asbestos deposits are of importance. Sections of gold mines are shown. This county has the only electric iron smelter in the State, now reducing iron and manganese ores. Siskiyou is noted for its many small gold mines and placer workings. Trinity is a mountainous area. Quartz mining is not considered to be on a large scale, but hydraulicking and dredging are. The asbestos deposits are promising.

Amador County

After being reported as sold many times during recent years, the old Eureka mine at Sutter Creek has really been sold to New York people, represented by Walter Beam of Denver. The property was owned by Mrs. Hetty Green, who allowed it to be idle for 31 years.

Calaveras County

Underground work at the Utica mine at Angels was suspended on December 25, when 100 men were paid off. Nothing is known of future plans. The mill is crushing ore from the Goldcliffe mine, owned by the Utica company. J. F. Martin is superintendent.

Eldorado County

The Guilford mill, 2½ miles from Placerville, was held up and robbed of $1200 of amalgam on December 25, the bandits scraping the plates in expert style.

Nevada County

Following its usual custom, the North Star Mines Co. on December 24 gave each employee receiving $3 per day a $10 coin, and each receiving less than that wage, a $5 coin.

Shasta County

(Special Correspondence.)—The Mammoth Copper Co. has started a lower adit from the Friday-Lowden mine to develop the main orebody 400 ft. below the present lowest workings. It will be 7½ by 8½ ft., and 5000 ft. long. It will form the main working adit, and be known as No. 6 tunnel. Three blast-furnaces are reducing copper ore, including 300 tons received daily from the Balaklala company. Shipments of selected zinc ore are being made to Eastern plants at the rate of 250 tons per day. Arrangements have been made recently for more extensive work at the Sutro, Stowell, and other mines.

Operations have been resumed at the Shasta Belmont, near Copper City, with William Arps in charge of affairs. The property has been developed to a limited extent by short adits and some rich ore exposed. A good wagon-road extends from the mine to Heroult, on the railroad, and small shipments will be made to the Mammoth smelter. A new main adit has been started, designed to open the ore at fair depth. The ore contains copper and zinc, with some gold and silver.

Large quantities of supplies have been shipped to the Midas mine, at Harrison Gulch, and preparations made for more extensive work. Unwatering of the deep levels of the Midas will be pushed, and development of the Gold Hill, Bonanza, and other properties carried forward. More units will be added to the reduction plant in the early spring.

It is estimated by conservative mine operators that the mineral output of Shasta county for 1915 will approximate $7,000,000. The increase is due largely to the heavy output of zinc, and the higher price of copper. This year marks the first time that the extensive zinc-ore deposits have been turned to profitable account.

Redding, December 20.

The Crown Deep mine between Redding and Shasta is to be re-opened by the owner James Hulme. The power-line was stolen last year. In the past this mine was a good producer.

Sierra County

As was mentioned in the Press last week, a blast of 11 tons of powder was to be set off at the Brandy City gravel mines. The powder, in 25-lb. sacks, was arranged in a drift, tamped, and connected with the outside by fuses. These were lit on December 23 at 3:30 p.m.. Eight men then retired to the blacksmith-shop, which is surrounded by high banks 200 yards distant. Some of the powder exploded, the remainder catching fire and blowing out from the mouth of the drift. The flame, smoke, and fume quickly spread over the whole area, enveloping the men. As a result four men were asphyxiated, while the others are still very ill. The fume was smelt as far away as Comptonville, seven miles distant; while at Brandy City, a half-mile from the mine, several people were almost overcome. The cause of the accident is unknown. Previous large blasts at the same property were always successful.

Trinity County

Most of the small mines in the Carrville district are closed for the winter, but the Bonanza King has 40 men in its mine and mill, while the Strode is leased, with five stamps dropping.

Hydraulicking has been started at the Paulsen ranch, a half-mile from Lewiston. The property is of considerable extent. An eight-mile canal delivers 600 miner's inches of water with a 200-ft. head. The gravel averages 20 ft. in depth. Seven men are employed. The owner is the Bablou Mining Company.

COLORADO

Clear Creek County

(Special Correspondence.)—A two-foot body of smelting ore has been cut on the 100-ft. level of the Albro mine situated on Albro mountain. Shipments are at the rate of two carloads per week, returning $65 gold and silver per ton. Earl Dingle is lessee.——The Wyoming Valley adit in Gilson gulch is being extended steadily. The manager, J. J. Hoban, states that an electric compressor is to be installed at once. Shipments have been started from the White property of the Little Giant Mining Co., on Red Elephant mountain. The ore is being extracted from the vein cut 2000 ft. from the portal of the Commodore adit, and returns averaging $70 per ton in gold, silver, and lead are being received.——Work will be resumed on January 1 at the Stanley mine. The adit will be driven to intersect a number of cross-veins, while development will also be done on several levels of the shaft workings. H. J. Wolff is manager. ——Machine-drills were started this week at the McClelland adit, the portal of which is situated near Dumont. There will be no cessation of work until 3000 ft. has been driven. This will take the heading to the base of the Lamartine mine. L. W. Shaffer is manager.——Jenkins and Johnson, leasing on the Pozo mine, are making an average net earning of $2000 per month. Operations are above the Newhouse adit.

Idaho Springs, December 19.

Gilpin County

On every 1000 shares in the Cashier Gold Mining & Reduction Co., which operates the Pittsburg mine in lower Russell gulch, a dividend of $15 has been paid. The employees were given a 10-lb. turkey each. The shaft is to be sunk to 100 ft. An electric pump has been installed at 1000 ft. Recent shipments were high in gold, silver, and copper. W. Auger is superintendent.

Good settlements are reported from the Senator, Gilpin-Eureka, Ingalls, Powers, New Treasury, and Black Hawk mines.

Hinsdale County

The Colorado-Utah Mining & Operating Co., which has a lease of the Golden Fleece mine, has erected a concentrating-plant.

TELLER COUNTY (CRIPPLE CREEK)

The Elkton shaft is down 1438 ft. No. 17 level station is to be cut. The main vein will be cut on the dip near the shaft at the bottom level, and ore should be mined early in February. Water is receding at the rate of 21½ ft. per month. As the Roosevelt drainage tunnel approaches the shaft, now less than 500 ft. distant, the water recession is more rapid.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

It is considered probable that the Chicago, Milwaukee, and St. Paul railroad will be constructed to this region.

At 900 ft. in the Marsh mine 7 ft. of ore has been opened, 3 ft. being suitable for shipment. The mill is making high recoveries.

A cross-cut in the Patuxent, Nine-Mile district, has passed through 60 ft. of ore, 6 ft. of which contains 30% lead, with some zinc. Another good vein is being developed in this mine, owned mainly by James F. Callahan, well known in Idaho.

For the sum of $150,000, A. Swan of Burke has secured an option to purchase and lease the Coeur d'Alene Mining & Concentrating Co.'s property. A royalty of 15% of the net smelter returns is to be paid the mining company, which will apply on payments falling due.

The first of the regular monthly dividends of 7c. per share, equal to $70,000, was paid by the Hecla company at Burke on December 20. An extra of 3c. was also paid. The total for 1915 was $565,000, and $3,755,000 to date.

Concentrates assaying up to 35% copper and 90 to 100 oz. silver, are being shipped from the National mill at Mullan to the smelter. A good recovery is reported from the plant.

The Anaconda Copper company has secured a three-year bond on the Douglas mine in the Pine Creek district for the sum of $261,000. An initial payment of $100,000 has been made. A mill and other machinery is to be ordered at once. The ore contains zinc, which will be treated at the new plant at Great Falls, Montana.

Dividends of Coeur d'Alene companies are as follows, according to *The Wallace Miner:*

December.	
Caledonia	$ 52,100
Bunker Hill & Sullivan	163,500
Interstate-Callahan	697,485
Hecla	100,000
Federal	120,000
Hercules	200,000
Success	45,000
Total	$1,378,085

Total 1915.	
Bunker Hill & Sullivan	$1,062,750
Caledonia	677,300
Federal	480,000
Hecla	565,000
Hercules	2,250,000
Interstate-Callahan	2,557,445
Stewart	804,934
Success	555,000
Total	$8,952,429

MICHIGAN

THE COPPER COUNTRY

Two more stamps are to be added to the Ahmeek mill; they should increase the annual output by 7,000,000 lb. of copper. Four shafts are supplying ore.

A number of additions and improvements are being made at the White Pine mine and mill. The new railroad to the property was completed and opened for traffic last week.

The Franklin mill crushed about 30,000 tons in December. Fifty machine-drills are at work underground.

MISSOURI

JASPER COUNTY

Owing to the rise in prices for concentrate the expected $25,000,000 output for the region will be exceeded. The yield during the week ended December 17 was 6087 tons blende, 518 tons calamine, and 904 tons lead, averaging $89.65, $64.47, and $69.81 per ton respectively. The total value was $545,736, and for 51 weeks, $24,645,953.

In the zinc-lead region there are approximately 300 mines being operated, half of which are using electric power to great advantage. Current for some districts is not yet available, but provision has been made for motors. It is estimated that some time ago motor-driven pumps were lifting 86,000,000 gal. of water per day.

MONTANA

LINCOLN COUNTY

Spokane people, headed by J. E. Wallace, W. W. Wallace, and C. Robinson, have organized the Diamond Hitch Mining Co. to operate the Diamond Hitch and Cabinet Queen lead-zinc claims near Troy. In the Troy mine the Wallace Bros. are opening good lead-zinc ore. An adit from this mine will develop the others.

SILVERBOW COUNTY

In his report for the year ended November 30, 1915, the deputy state mine inspector, Mr. McGrath, considers that conditions in this county were never better, nor the future brighter. There are 14,067 men employed, receiving $1,595,845 in wages during September. This does not include lessees and prospectors. As has been mentioned in previous issues of the PRESS, many mines are being re-opened.

Some of the taxpayers of this county are as follows: Anaconda Copper Mining Co., $272,262; Butte & Superior Copper Co., $81,264; Butte, Anaconda & Pacific railroad, $11,644; Elm Orlu Mining Co., $11,066; and North Butte Mining Co., $10,879.

The *Butte Miner* of December 19 is a special issue of 56 pages, a number of which are devoted to local mining.

NEVADA

CLARK COUNTY

Little has been heard of the Boss platinum mine of late. It was under option to California people, but has reverted to the original owners, S. E. Yount, F. A. Hale, and O. J. Fisk. Of the purchase price of $150,000, only $50,000 was paid. An adit is being driven to cut the rich vein recently opened.

Goodsprings, Platina, and Smithsonite districts are busy.

ELKO COUNTY

Operators in the Dolly Varden district, near Currie, are optimistic as to the future. More work has been done in the last four months than in a previous year.

ESMERALDA COUNTY

The final report of the Goldfield Consolidated for November shows that 32,100 tons of ore gave a net profit of $52,706. Costs totaled $4.73 per ton. Development amounted to 2412 ft., at $5.75 per foot. Lessees mined 219 tons of ore worth $4394; of this the company received $2213, less transport and treatment.

NYE COUNTY

Eight companies and several lessees at Tonopah last week produced a total of 10,423 tons of ore, worth $213,574.

The Belmont shipped 153,100 oz. bullion. On December 19 the refinery at the Tonopah mill of this company was destroyed by fire, caused by an oil-supply pipe breaking.

At 1540 ft. in the Extension, the Murray vein has been opened by a cross-cut from the Victor shaft. So far the metal-value is low. A bullion shipment consisted of 87,165 ounces.

In the Tonopah Mining Co.'s properties development totaled

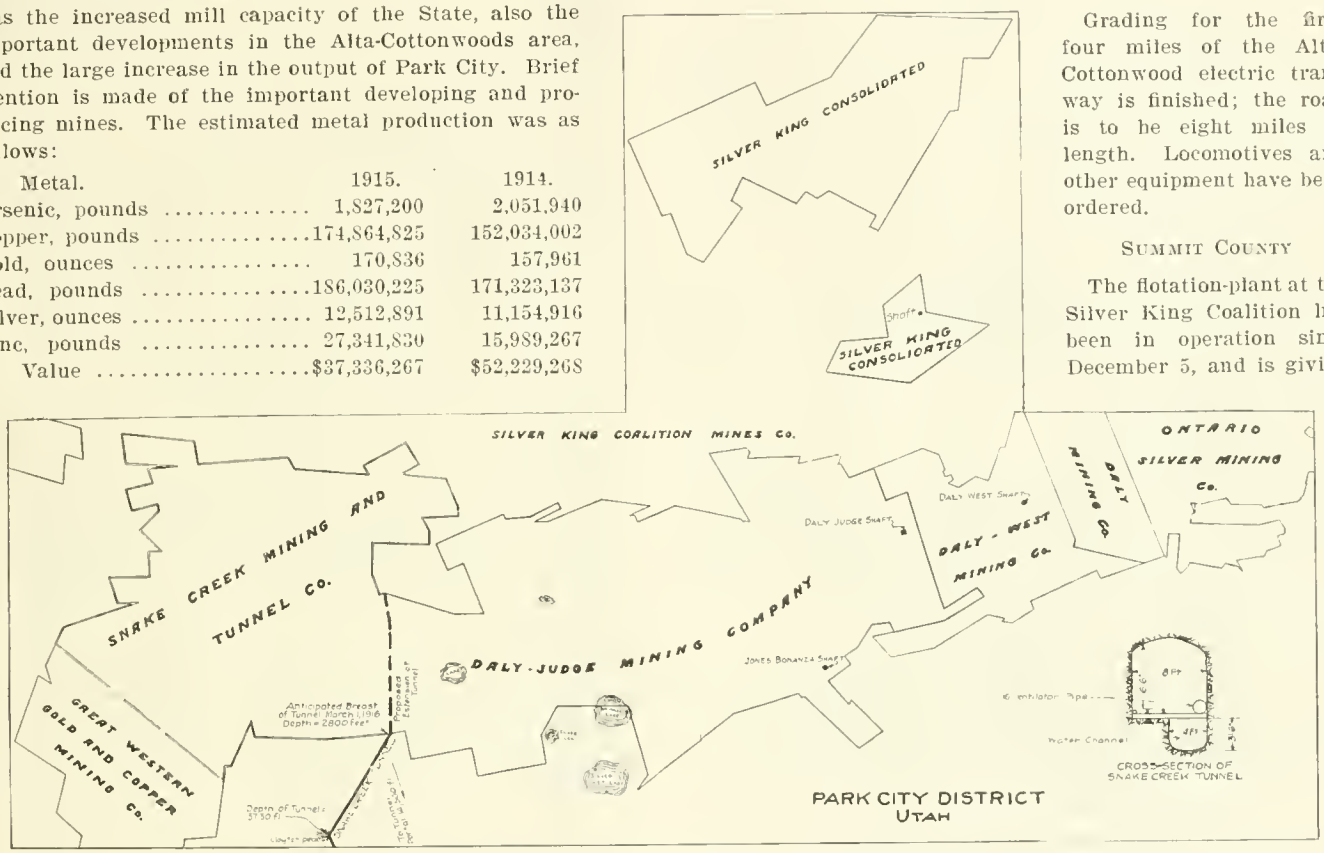
344 ft., considerably above the average, with encouraging results. The plant at Millers treated 2865 tons of ore.

The Cash Boy, Halifax, and North Star made small shipments to the West End mill.

UTAH

Of the 120 pages in its special issue, of December 18, the *Deseret Evening News* devotes 13 pages to mining. It states that "great as has been the advances in mining in Utah in the past, they have been as nothing in comparison with the progress made in 1915." This was reflected on transactions at the Salt Lake Stock Exchange, where 13,000,000 more shares were sold than in 1914. One of the greatest features was the increased mill capacity of the State, also the important developments in the Alta-Cottonwoods area, and the large increase in the output of Park City. Brief mention is made of the important developing and producing mines. The estimated metal production was as follows:

Metal.	1915.	1914.
Arsenic, pounds	1,827,200	2,051,940
Copper, pounds	174,864,825	152,034,002
Gold, ounces	170,836	157,961
Lead, pounds	186,030,225	171,323,137
Silver, ounces	12,512,891	11,154,916
Zinc, pounds	27,341,830	15,989,267
Value	$37,336,267	$52,229,268



Dividends totaled $10,136,636, against $7,107,822 in 1914. The total disbursements are $128,384,153, from a metal output of $724,609,605.

The Bingham district made an interesting showing on account of new development, and 33 mines yielded a total of 10,176,984 tons of ore worth $33,786,250, mostly in copper from the Utah Copper Company.

In the Alta-Cottonwoods a year ago only 17 mines were worked, employing 100 men; now there are 70 and 700, respectively. Ore shipments in the past two years were $221,000 and $1,000,000, showing the amount of work done. Good progress is being made on the new electric railroad to serve the region. The U. S. Geological Survey has just published a bulletin, No. 620-I, on this region.

At Park City 12 mines in 1914 shipped 62,606 tons, while in 1915 the figures were 18 and 91,477, respectively. Re-treatment of tailing is a feature of present operations. Much new equipment has been erected. The Snake Creek tunnel is now in over 13,000 feet.

There were seven dividend-payers at Tintic. Ore shipments for 11 months show a fair increase over 1914.

Beaver County

Fortuna continues to expand; 75 miners are busy; there are more prospectors; and extensive development is planned by several companies. The first shipment of ore from the district was sold last week to the U. S. R. & M. Co. It consisted of 21 tons assaying 3.28 oz. gold and 2 oz. silver per ton, from the Davis lease.

Juab County

With a capital of $2,000,000 the Tintic Tunnel Co. was incorporated last week. It will drive a drainage-tunnel about five miles long, that will reach a depth of 2300 ft. below the collar of Iron Blossom No. 2. The grade will be 12 ft. per mile. There will be room for a double-track electric line, and a drainage-ditch. It is thought that the water developed will pay the cost of the work.

Salt Lake County

Grading for the first four miles of the Alta-Cottonwood electric tramway is finished; the road is to be eight miles in length. Locomotives and other equipment have been ordered.

Summit County

The flotation-plant at the Silver King Coalition has been in operation since December 5, and is giving excellent results, the recovery of lead and silver being from 90 to 95 and 90 to 93%, respectively.

Utah County

To develop and extract various substances from the oil-shale in Kyune canyon, the Utah Oil Shale Products Co. has been organized with a capital of $300,000. The John D. Scott process will be used. L. P. Palmer is president and A. H. Northrop vice-president.

WASHINGTON

Chelan County

(Special Correspondence.)—A car of antimonial ore from the Gold Creek mine, in the Methow district, has been shipped to Chicago. The company is preparing to build a small smelter at the mine this winter.

Methow, December 25.

Stevens County

Five hundred tons of zinc carbonate ore has been contracted to go to Donora, Pennsylvania, from the Great Western mine, seven miles south-east of Northport. The ore assays 30% zinc, 5% iron, and 1% sulphur. The daily shipment will be 15 tons. Development is good in this mine operated by the Norman Mines Company.

CANADA

British Columbia

The Granby company's furnaces are reducing 900 tons of ore each per day, the Anyox total in November being 60,000 tons. The converter-plant here has been closed for the winter, matte being sent to the smelter at Grand Forks. Costs of producing copper at Anyox are expected to be reduced to 8c. per pound.

On January 10 the Standard Silver-Lead company will pay 2½c per share, equal to $50,000, and making a total of $1,800,000.

Ontario

In November the McIntyre mill at Porcupine treated 8657 tons of $7.29 ore with 95.52% recovery, at a cost of $1.07 per ton. The profit was $25,050. The ore averages $11.17 per ton at 600 ft. depth, at 700 ft. it is erratic, from 10c. to $10.40. The Extension shaft is down to 885 ft. The McIntyre-Jupiter Mines, Ltd., has been formed with a capital of $2,000,000, of which the McIntyre-Porcupine Mines, Ltd., takes 955,000 shares and the Jupiter Mines, Ltd., receives 943,893 shares and $60,000 for its property.

No. 8 vein of the Tough-Oakes has been cut at 250 ft. depth. Other developments are very satisfactory.

At a depth of 425 ft. the Hollinger company has started a long drift to connect with a shaft at the Vipond boundary. This will take 18 months, but will result in rapid underground electric haulage.

Near Timmins the Hayden Gold Mines Co. has 11 men employed at exploration.

A 3-in. vein of 3000-oz. ore has been cut in a winze below the 350-ft. level of the Chambers-Ferland. The vein is in conglomerate, 37 ft. from the Nipissing boundary.

After January 1, 1916, the Crown Reserve company need not pay royalty on ore extracted to the Ontario government, but will pay the 3% profits tax, which applies when an annual profit of more than $10,000 is made.

The Triumph Mines Limited has been organized with a capital of $3,000,000 to develop the Success claims at Porcupine, succeeding the Porcupine-Success Gold Mines Ltd. The western part of the property has been extensively trenched, disclosing 30 veins. Shaft-sinking is to be commenced.

The Hollinger mine and mill employs 1100 men, also contractors. Sinking continues.

A 6 ft. by 22-in. Hardinge ball-mill, one 5 by 11-ft. tube-mill, three 22 by 18-ft. agitators, and five 32 by 8-ft. Dorr thickeners are soon to be installed in the McIntyre mill, to increase the daily capacity from 300 to 450 tons.

By means of a device (to be patented) of C. A. Randall of the Tough-Oakes mill at Kirkland Lake, the capacity of the plant has been increased from 80 to 110 tons daily.

KOREA

In November the Oriental Consolidated mines and plants yielded $144,800. The ore was above average grade.

MEXICO

Hidalgo

During October the Santa Gertrudis mill treated 20,503 tons of ore for a profit of $34,000.

Sonora

Eight furnaces are in blast at the Cananea Consolidated.——The Moctezuma mine and mill will be re-started in a few days. The railroad to Nacozari is not repaired yet.——El Tigre is to resume in a few days.

PHILIPPINE ISLANDS

After being erected in fast time the new mill of the Benguet Consolidated company at Baguio had its first clean-up near the middle of October. A new vein of better grade ore has been opened. C. M. Eye is in charge.

PERSONAL

Frank A. Crampton is at Philadelphia.

L. R. Hudson has returned to El Tigre, Sonora, Mexico.

J. S. Williams has returned to Nacozari, Sonora, Mexico.

Arthur R. Weigall has arrived in San Francisco from Korea.

Willard Mallery is working antimony ore at Bernice, Nevada.

Walter J. Radford has returned here from Breckenridge, Colorado.

E. C. Bloomfield has arrived from the Altai, having been in Siberia three years.

O. A. Turner is manager for the Copperfield Mining Co. at Gross Springs, Arizona.

S. J. Lewis spent the Christmas holidays at Monterrey, returning to Mexico City.

Bertram Hunt is now connected with Maurice, Hadlan & Co., at Medellin, Colombia.

Norman C. Stines, manager of the Sissert copper mine, Ural region, Russia, is visiting Berkeley.

J. M. Mitchell-Roberts, metallurgist with the Seoul Mining Co., in Korea, is on a visit to California.

W. J. Lakeland sailed by the *Ventura* on December 28 on his return to Burma, by way of Australia.

E. H. Hamilton is consulting metallurgist with the Canadian Consolidated Smelting Co., at Trail, B. C.

John D. Pope, 11 years general manager of the North Butte mine, has resigned; Norman Braley succeeds him.

William Thum, superintendent of the U. S. Metals Refining Co.'s plant at Grasselli, Indiana, is at Kennett, California.

John Henry Rickard has arrived in San Francisco to superintend the antimony smelter of the Chapman Smelting Co., in this city.

Gelasio Caetani, now an officer in the Italian engineering corps, has been wounded in action and recommended for the military medal.

B. F. P. Römer has left Amsterdam on his way to Batavia, Dutch East Indies, where he will make geological examinations for the Government.

Arthur Gifford, formerly superintendent of the Mysore mine, died at Madras in December.

H. L. Twite, of the mining engineering firm of Twite & Stannard, has been killed in action while serving as a lieutenant with the Royal Engineers in France.

The U. S. Civil Service Commission, Washington, D. C., announces an open competitive examination for metallographist, for men only. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the War Department, for duty at Watertown arsenal, Massachusetts, at a salary of $2000 per year, and vacancies as they may occur in positions requiring similar qualifications. The appointee to this position will have general but subordinate charge of the testing laboratory at the arsenal; direct the preparation of metal specimens for microscopic examination, the photographing of the same and the interpretation of the appearance of the specimens under the microscope, and prescribe proper heat treatment, etc., for specimens examined. Applications must be filed at Washington by January 25.

The Commission also announces an examination for civil engineer, applications to be in by January 18. Eligibles from this will be available for vacancies in the Philippine service, at $1800 to $3000 per year. A knowledge of design and construction of various equipment, and also of water supply and irrigation is necessary.

THE METAL MARKET

METAL PRICES.

San Francisco, December 29.

	Cents per pound.
Antimony	40
Electrolytic copper	23.50
Pig lead	5.65—5.85
Quicksilver (per flask)	$135
Spelter	20
Tin	40
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, December 29.

Antimony: market weaker; 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica per ton	12
Magnesite: plastic, no iron and lime, calcined, per ton	60—65
Magnesite: refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	35—15

At Boulder, Colorado, on December 28, 60% tungsten ore realized $47.50 per unit.

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, December 29.—Copper is excited and active; lead is firm owing to export demand; zinc is quiet but firm.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 23	54.00	Nov. 17	50.46
" 24	53.87	" 24	52.35

June	56.43	49.03	Dec.	49.27	....

An error in silver prices last week gave an average of 55.22c.; this should have been 54.23 cents.

The President of Uruguay has recommended to that country's Congress that a bill be passed to coin 5,000,000 pesos, equal to $5,170,000, say 10,000,000 oz. silver, but old coins are to be melted, yet some new metal will be required.

Profit taking by India, and a lull in European buying caused a slight weakening lately, but there is not much set-back anticipated. The Chinese New Year occurs on February 4; this is a stiffening factor. The shortage of British coin is not yet satisfied; the Master of the Royal Mint is appealing to the suppliers of gas to arrange for the clearance of automatic gas-meters at more frequent intervals, with a view to the return of the coin into active circulation as speedily as possible.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports during the week ended December 11 totaled 15,793,210 lb., worth $2,962,163. England got 2,637,492; France, 5,599,216; Italy, 4,282,917; and Sweden, 1,837,526 lb. Imports amounted to 7,470,514 lb., valued at $1,180,923. Of this, Canada sent 1,901,362; Chile, 940,579; and Peru, 4,042,961 pounds.

Dividends declared are as follows: Anaconda, $1.50; Champion, $2, making $31 for 1915, against nothing in 1914; Greene Consolidated, 50c.; North Butte, 50c.; Osceola, $3; Tennessee, 75c.; and U. S. R. & M. Co., 75c. on common stock.

The past year was the most profitable for the A. S. & R. Co. in the United States.

The Interstate-Callahan company, Idaho, has paid $1.50 per share, equal to $697,485, making $2,557,495 since April last.

Net earnings of the American Zinc, Lead & Smelting Co. in 1915 were $5,000,000; or $20 per share, all debts are paid.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Date.		Week ending	
Dec. 1	105.00	Dec. 15	130.00
" 8	115.00	" 22	130.00
		" 29	135.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	95.00
Feb.	39.00	60.00	Aug.	80.00	93.75
Mch.	39.00	78.00	Sept.	76.25	91.00
Apr.	38.90	77.50	Oct.	53.00	92.90
May	39.00	75.00	Nov.	55.00	101.50
June	38.60	90.00	Dec.	53.10	123.00

The average price for 1915 was $85.80 per flask.

According to H. D. McCaskey of the U. S. Geological Survey, this country produced 20,681 flasks in 1915, an increase of 4133 flasks, but the value was more than double. All States showed advances.

Tin is quiet at 39 cents.

Eastern Metal Market

New York, December 23

Contrary to expectations, a revival in the demand for copper set in about December 15, and the climax came yesterday, the 22nd, when, through the United Metals Selling Co., the British government purchased 60,000 tons, or 120,000,000 lb., of copper for delivery at the rate of 5000 tons per month throughout 1916. The price was over 20c., and is understood to have been about 20.50c. From December 15 the quotation advanced almost daily, and prior to the news of the big purchase, 20.50c was quoted. Exports for the month were good. Spot zinc is scarce, and this fact, together with a fair demand has sustained prices. The unwillingness of consumers to buy far-off deliveries of zinc is pronounced. Lead is firm at 5.40c., New York, and is principally supported by the strong export situation. Large consumers of tin were roused to activity by the report that Great Britain would limit exports until there was 4000 tons in stock. Antimony is more plentiful, but the quotation is maintained. Aluminum is easier, with fewer buyers in evidence.

The great demand for steel continues; ruling prices are the highest of many years. Several of the railroads have laid embargoes on shipments of iron and steel to New York for export, one result of which will be the shipping of steel to domestic consumers, which they might not have received otherwise. The entire trouble is due to the lack of ships to carry products abroad. Many thousands of loaded freight-cars, one estimate is 35,000, have been standing at or near New York harbor, unable to unload. There is a shortage of lighterage facilities also. In some centres the situation has created a shortage of coal and coke.

COPPER

On the strength of the transaction before mentioned, the domestic quotation for electrolytic went to 20.75 and 21c., 30 days, delivered. Lake copper, the prices of which are on about par with electrolytic, is in an extremely strong position, with some of its producers sold up until March next. About December 15, following a period of quiet, some good inquiries appeared in the market and proved the forerunner of an excellent movement, something which was not expected in view of the heavy buying of previous weeks. Copper was taken, mostly for March and April deliveries at 19.87 to 20c., and by the 17th the market was firm at 20c., 30 days, delivered. By that date practically all re-sale metal had been absorbed, and the producers had the field to themselves. On the 20th, buyers were particularly active, and whereas 20c. could have been done in the morning, the market at midday went up with a rush to 20.25c.; good sales were made at the latter figure. Coincident with the appearance of the large inquiries there was talk of a possible shortage of copper, of the possibility of consumption outstripping production, and persons in close touch with the producers are commencing to take the report seriously. War demand has continued the principal motive power behind activity, though the wire-mills have been heavier purchasers in the past few days. In London the trend of electrolytic copper has been upward, the quotation on September 21 being £100 10s. European statistics, as cabled to the New York Metal Exchange on December 20, showed that stocks in Great Britain on the 15th totaled 11,233 long tons, against 13,572 tons, November 30, and 17,118 tons, November 15. Fine copper in France amounted to 1262 tons on December 15, against 1473 tons on November 30, and 1645 tons on November 15. Exports in December total 24,972 tons.

ZINC

For upward of a week the market price of prompt spelter has been close to 17.50c., New York. Lower has been quoted, it is charged, in the interest of some who seek to depress the market. On the other hand, sales of spot have been made at 17.75c., New York. The scarcity of prompt and near-by metal is insisted on by various producers. The demand has been good for deliveries to the end of the first quarter, but consumers are showing but little interest in deliveries further off, and this despite offerings at 15.50 to 16c., New York. St. Louis quotations are about 25 points under New York prices. Second-quarter metal is nominal at 13.30 to 14c., New York. Exports in December total 5661 tons.

LEAD

The strength of lead today unquestionably lies in the export demand. If the metal were to be had it would bring 5.50c., New York, for shipment to foreign consumers. Since the leading interest advanced its New York quotation to 5.40 (December 14) the independents have held to that figure. A few nervous consumers entered the market as a result of the advance, but the majority are proceeding cautiously and have not rushed to buy. Prior to the advance the market was weak, and both sellers and consumers were mystified by the advance. Inquiry has been light. Exports so far this month total 5908 tons.

TIN

The report published last week that England intended to curtail shipments of tin to this country until it had 4000 tons in its warehouses caused a rush to buy here, and on December 16 about 500 tons was taken by large consumers and dealers. On the 17th probably 300 tons more was purchased, but thereafter the market became quiet, and not even concessions in price could arouse the interest of buyers. The report that England is to regulate shipments, so far not officially confirmed, is generally accepted by the trade. It is regarded as reasonable that it should want to protect itself against delays in shipments from the Far East, and from possible interference with them. The New York quotation on December 15 was 37.75; 17th, 40; 21st, 39.50; and on the 22nd, 39c. Up to December 21, 3605 tons had arrived in the month, and there was afloat on that day 5478 tons.

ANTIMONY

Chinese and Japanese grades are quoted at 39c., duty paid, in a market considerably easier because of the arrival of several hundred tons. The plant of the Magnolia Metal Co., Matawan, New Jersey, was partly destroyed by fire on December 17. The company has been making antimony from domestic ores. Cookson's antimony at London is nominally quoted at £100 per ton.

ALUMINUM

The market for aluminum 99% pure is easier at 56 to 58c. per pound. Buyers are fewer and their requirements are more easily satisfied with scrap metal and wire. The latter, as previously stated, is being taken down and replaced with copper wire.

According to the U. S. Geological Survey, the past year's metal output was an increase of $250,000,000 over that of 1914. The production is estimated as follows: copper, 1,365,000,000 lb.; gold, increase of $7,000,000; silver, increase of 4,000,000 oz.; iron, increase of 6,500,000 tons; zinc, 425,000 tons; lead, 515,000 tons; quicksilver, 20,681 flasks, an increase of 25%, with small increases in coal, coke, oil, and portland cement. The Western States' metal output shows an increase of $130,000,000. It is probable that final figures for 1915 will make a total of $2,500,000,000.

Metal Production in 1915

The U. S. Geological Survey has issued its preliminary statements regarding the mineral output of certain states, from which the following is abstracted:

ARIZONA

The output of gold, silver, copper, lead, and zinc at mines was valued at $88,551,000, an increase of nearly 48% from that of 1914, which was $59,956,029. There was very little change in the output of gold, but there were notable increases in the other metals, especially in lead and zinc. Increased prices made a difference of nearly $26,000,000 in copper, $400,000 in lead, and over $2,000,000 in zinc, according to estimates of V. C. Heikes.

A record production of silver was made, the output increasing from 4,377,994 to 5,458,000 oz. or over 24%. The greater part of the silver, as formerly, came from the copper ores, but the increase in the shipments of silver-lead ores also contributed to the increase. The Commonwealth mine, at Pearce, was treating approximately 10,000 tons of ore per month, making bullion containing principally silver.

Arizona is the leading copper-producing State of the country, and had an output of nearly 450,000,000 lb. in 1915, an increase of nearly 57,000,000 lb. in spite of the strike in the Clifton-Morenci district. Great increases were made at the smelting plants at the Calumet & Arizona, Copper Queen, United Verde, Hayden, International at Miami, and Consolidated Arizona at Humboldt.

The mine output of lead increased from 15,003,068 to $22,272,000 lb., or 48 per cent.

The mine production of zinc, estimated as recoverable spelter, increased from 9,792,337 to 17,729,000 lb., an increase of 81%. It came almost entirely from the Golconda and Tennessee mines, in Mohave county.

For the first eleven months of 1915 the metal mines of Arizona contributed nearly $11,000,000 in dividends, the principal ones being the United Verde, Miami, Calumet & Arizona, Ray Consolidated, Superior & Pittsburg, Old Dominion, Shattuck, Arizona Copper, United Globe, Tom Reed, and Magma.

COLORADO

The mine output of Colorado metals for eleven months of 1915, with an estimate for December, from data compiled by Charles W. Henderson, indicates a yield for the year of $22,330,000 in gold, 7,080,000 oz. silver, 66,664,000 lb. of lead (in terms of lead in lead bullion and lead in leaded-zinc oxide), 7,100,000 lb. of copper, and 100,000,000 lb. of zinc (in terms of spelter and zinc in zinc oxide), with a total value of $13,100,000, compared with $19,883,105, 8,796,065 oz. 74,211,898 lb., 6,639,173 lb., and 96,774,960 lb., respectively, with a total value of $33,460,126, in 1914.

The quantity treated by the Globe, Leadville, Pueblo, Durango, and Salida smelters was approximately the same as in 1914.

The gold output of Cripple Creek (Teller county) was $13,539,245, an increase of $1,543,129. The yield was also $507,328 larger than the 1908 yield, which was the largest yearly output since 1906. Cripple Creek, to the end of 1915 has produced $272,326,000.

Lake county, chiefly from Leadville, but also including the Lackawanna Gulch and St. Kevin lode districts and the Arkansas River dredge district, produced $2,261,000 in gold, 2,660,000 oz. silver, 20,000,000 lb. lead, 1,840,000 lb. copper, and 71,000,000 lb. zinc, with a total value of $14,000,000, against $1,571,451, 3,810,830 oz., 26,784,615 lb., 2,382,910 lb., 78,763,334 lb., respectively, with a total value of $9,057,297 in 1914.

The San Juan region of Dolores, La Plata, Ouray, San Juan, and San Miguel counties produced $3,890,000 gold, 2,250,000 oz. silver, 13,800,000 lb. lead, 3,530,000 lb. copper, and 4,000,000 lb. zinc, compared with $3,969,857, 2,515,437 oz., 11,861,766 lb., 2,379,639 lb., and 1,382,334 lb., respectively, in 1914.

IDAHO

The output of gold, silver, copper, lead, and zinc from ores sold or treated from Idaho mines in 1915, had a total value of about $37,780,000. This is an increase of more than 53% over the production of 1914, which was valued at $24,645,848. There was no great change in the output of gold and a slight increase in that of silver, but there were material increases in the production of copper, lead, and zinc, especially of zinc. The increase in the total value of these metals, amounting to over $13,000,000, was due largely to the increased price of lead and zinc. These estimates are reported by C. N. Gerry.

The production of silver increased from 12,479,516 oz. to 13,000,000 oz., or more than 4%. The price of silver, however, was comparatively low and the value of the output was over $400,000 less than in 1914.

The output of copper increased from 6,445,187 to 7,169,000 pounds.

The mine output of lead, which is the main mineral product in Idaho, increased from 348,526,069 to 377,000,000 lb. A large part of this output, however, had not reached the smelters at the close of the year. This is an increase of over 8% in quantity and nearly $4,000,000 in value. Nearly all the large mines of the Coeur d'Alene region produced more lead in 1915 than in 1914 on account of the effort to market the ore the last half of 1915. The Yreka district around Wardner, alone produced 169,500,000 lb. of lead against 162,471,235 lb. in 1914.

Shipments of zinc ore and concentrate increased from 54,754 tons in 1914 to 97,000 tons in 1915. The shipments contained about 80,000,000 lb. of recoverable spelter, valued at over $11,000,000. On account of the unusual price for zinc in 1915, the zinc produced in the State was more valuable than the gold, silver, and copper combined.

The principal dividend payers in 1915 were the Consolidated Interstate-Callahan, Hercules, Bunker Hill & Sullivan, Caledonia, Federal, Hecla, Stewart, and Success, which will pay in all nearly $9,000,000.

MONTANA

The value of the output of gold, silver, copper, lead, and zinc from Montana mines in 1915 was nearly $87,000,000, an increase of more than 81% over the total value of the same metals in 1914, which was $47,849,747, and is the greatest annual value of metals produced in Montana. There were increases in the output of all metals, but especially of lead and zinc. Though quantities show increases, the large increase in value was even more the result of a great rise in prices. The figures are derived from preliminary estimates by Victor C. Heikes.

The mine output of gold was valued at nearly $5,000,000, against $4,117,911 in 1914, an increase of over 21%. There was a larger gold output from placers, particularly from dredging in Alder gulch, in Madison county. The production of gold from silicious ores also increased.

The mine output of silver increased from 12,016,460 to 14,500,000 oz., increase of nearly 21%. The increase was due not only to the enlarged output of copper ore, which supplies the greater part of the silver, but to the great impetus given to the marketing of zinc ores.

Montana's greatest asset is copper, the output of which increased from 233,229,640 to 275,000,000 lb. This was an increase

of nearly 18%, over 1914, but the output did not reach that of 1913. In the early part of the year the mines were adjusting themselves to conditions imposed by the War, but as the price increased from 13.60c. in January to 19.75c. in July, every effort was made to market the metal.

The mine output of lead increased considerably—from 9,656,008 to slightly over 14,000,000 lb., increase of over 45%, due largely to the shipment of lead concentrate and of residue resulting from zinc smelting.

The mine production of zinc increased from 141,580,544 to 184,086,000 lb. The spelter output represented an increase of nearly 61% in quantity, but as the price of the metal increased from 6.30c. in January to 22.2c. in June there was an increase in the value of the output from $5,690,608 in 1914 to over $26,000,000 in 1915. The two main producers were the Butte & Superior and Elm Orlu mines, at Butte.

The largest dividend payers were the Anaconda, Butte & Superior, and North Butte.

NEVADA

The value of the 1915 output of gold, silver, copper, lead, and zinc from Nevada mines was approximately $34,566,000. This represents an increase of nearly 18% over the output of 1914. These estimates by V. C. Heikes of the Salt Lake City office of the Survey indicate a marked increase in zinc output, and increase in lead and copper yield, as compared with 1914. The copper production however was below that of 1913, when Nevada had a record output of over 90,000,000 lb. There was a slight increase in the gold production, but a decrease in silver largely in the Tonopah district, where the output was affected by the decreased price of silver.

The production of gold was valued at about $11,968,000, an increase of 4% over the production of 1914. The greater part of the gold came from silicious ores milled at Goldfield and about 20% of the total came from Tonopah.

The silver production decreased from 15,455,491 to 14,478,000 oz. The decrease was at Tonopah, where the mines were affected by the low price of silver. At the Comstock district of Storey county, the production was also lower, and the idleness of the Mason Valley copper smelter to a small extent lessened the silver output.

The mine production of copper increased from 60,986,450 to 67,480,000 lb. an increase of 10.6%. The total value of the output, on account of the high average price in 1915 increased from $8,111,198 to approximately $11,708,000.

The lead production increased from 12,809,655 to 14,782,000 lb., an increase of over 15%. This output, however, is not as great as that of 1913, when over 16,000,000 lb. was produced. There was great activity in the Yellow Pine district of Clark county, where lead-zinc ore is separated into lead and zinc products.

A great increase, nearly 62%, was made in the mine output of zinc from 12,980,232 to over 21,000,000 lb. As the price of the metal was abnormally high in 1915, the value of the output increased from $661,992 to about $2,993,000 in 1915. The Yellow Pine district of Clark county was by far the largest producer, but the Amalgamated Pioche property in Lincoln county made important shipments.

The main dividend payers of the State were the Nevada Consolidated, Goldfield Consolidated, Tonopah Mining, Tonopah Belmont, Tonopah Extension, Jumbo Extension, Jim Butler, Nevada Wonder, Seven Troughs Coalition, and West End. To December 1, 1915, the total in dividends was over $6,000,000.

NEW MEXICO

The output for 11 months, with an estimate for December, indicates a yield of $1,500,000 in gold, 2,032,000 oz. silver, 3,951,000 lb. lead, 72,000,000 lb. copper, and 24,640,000 lb. zinc (in terms of spelter and zinc in zinc oxide), compared with $1,171,696, 1,777,445 oz., 1,763,641 lb., 59,307,925 lb., and 18,403,392 lb. respectively. These preliminary figures were compiled by Charles W. Henderson.

The Mogollon district, Socorro county, 80 miles from Silver City (Grant county), continued to be the most productive district in New Mexico in output of gold and silver. The production in 1915 was $512,021 in gold and 1,319,460 oz. silver, as compared with $629,102 and 1,410,327 oz. in 1914.

Another important district was the Cochiti (Bland) district, Sandoval county, inactive from 1904 to 1914, but with a record from 1891 to 1904 of a production of $695,000 gold and $345,000 silver.

Copper has been an important metal in New Mexico. The output from 1845 to 1910 was 92,323,163 lb., and the total output to the end of 1915 was 318,027,798 lb. Since 1910 the increased production was due principally to the activity of the Chino Copper Co. Its gross output in 1915 was 69,375,000 lb. The Burro Mountain Copper Co.'s new 1000-ton mill in the Burro Mountain district, was operated only part of the time, but development of the mines continued on a large scale.

The yield of lead showed an appreciable increase.

Largely increased shipments of zinc carbonate and sulphide ores and zinc sulphide concentrates were made in 1915. The production of zinc ore and concentrates was 39,970 tons of 36.3%, compared with 29,459 tons of 37.53% in 1914.

SOUTH DAKOTA

The mine production of gold was $7,390,000, compared with $7,333,508 in 1914, and that of silver 193,000 oz., compared with 176,642 in 1914. A nominal quantity of lead was produced. These are preliminary estimates reported by Charles W. Henderson. The usual well-known producers contributed.

TEXAS

The output of Texas mines for 11 months, with an estimate for December, from preliminary figures reported by Charles W. Henderson, amounted to $2500 in gold, 705,000 oz. silver, 250,000 lb. lead, 50,000 lb. copper, and 33,000 lb. zinc, compared with $234, 530,817 oz., 149,027 lb., 23,760 lb., and 216,451 lb., in 1914, respectively.

WASHINGTON

The value of the mine output of gold, silver, copper, lead, and zinc in Washington decreased from $809,767 in 1914 to approximately $728,000 in 1915, according to preliminary estimates by C. N. Gerry. There were increases in copper and lead, to the extent of a return to normal production. There were shipments of zinc ore, the first since 1911. The gold and silver mines, however, showed decreased output, especially in the Republic mining district.

The mine production of gold, which is the most important metal of the State, decreased from $557,173 to $407,000.

The silver output decreased from 264,861 to 220,000 oz.

The mine output of copper increased from 778,728 to 915,000 lb., or over 17 per cent.

The production of lead from ores sold or treated increased from 65,507 to 230,000 pounds.

QUICKSILVER

The domestic output of quicksilver in 1915, based on preliminary figures collected from the individual producers by H. D. McCaskey, was 20,681 flasks, valued, at the average domestic price for the year at San Francisco (estimated at $85.50 per flask), at $1,768,225. Compared with the Survey's final statistics for 1914, which gave a production of 16,548 flasks, valued at $811,680 (the smallest since 1860), the output of 1915 shows an increase of 4133 flasks in quantity and of $956,545 in value. The value therefore more than doubled, owing to the greatly increased prices demanded, but the quantity increased only about 25%. The production was the largest in value since 1881, and the greatest in quantity since 1912.

EDITORIAL

T. A. RICKARD, Editor

STATISTICS issued by the State Mining Bureau indicate a remarkable increase of zinc production in California, from $20,381 in 1914 to $1,620,000 in 1915. On the other hand, the output of petroleum has diminished in value from $47,000,000 to $40,000,000, the yield having decreased by nearly 11 million barrels, although 240 new wells were drilled, increasing the total to 6500. The gold production is given as $22,850,000, the highest since 1870 and the largest of any state in the Union. Increased activity in the mining of tungsten, antimony, magnesite, and manganese is reported. In value of total output, Shasta county is first. The total mineral output is estimated at $95,211,000 for the year.

FOR some months past various brokers have been exceedingly active in the purchase of aluminum; first they bought scrap, and when that stock became exhausted they began to bid for aluminum electrical conductors in position, at prices that made it profitable to take down the aluminum and to replace it by copper of equivalent conductivity. Lately they have been purchasing such stock before it has been strung. If any owner of aluminum conductors, either in service or in the warehouse, still has any of it, either he has escaped the search of speculators or he is holding it for speculation on his own account. Where is it all going? Present evidence indicates that a complete answer may be found in the chemical literature of about four or five years ago, when a French chemist announced his discovery of an unusually powerful explosive, which he called 'ammonal,' the name being a combination of the chemical symbols of its component parts, ammonium nitrate and aluminum. A letter received recently from a German officer who was in the battle at Loos stated that in an examination of a position out of which the Germans were driven and which they afterward recovered, he counted some 640 dead in a space of about one hectare, of which less than 10% showed signs of mutilation. "The others were killed by that new terrible French explosive."

TUNGSTEN is in tremendous demand for the making of high-speed tool-steel. We take pleasure therefore in publishing a short account of the mining of scheelite, the tungstate of lime, in association with gold-bearing quartz at the Union Hill mine, in the Grass Valley district. In our 'Review of Mining' we also give notes concerning the Atolia mines. These have been worked for scheelite during the last ten years, but not with any remarkable profit until lately. Just now the output is at the rate of three carloads per month, say, 90 tons, of ore containing 30 to 50% tungstic acid. The few leases on the property lapsed at the end of 1915 and will not be renewed, as the company intends to re-organize its operations, which are under the direction of Atkins, Kroll & Co., although the directors are four well-known Californian mining engineers. As high-speed tool-steel is worth $3 per pound and tungsten ore is selling at the rate of $45 per unit, it is obvious why the search for the principal tungsten minerals—wolframite, hübnerite, and scheelite—has been intensified lately. It is likely to continue unless manufacturers elect to use molybdenum steel, as they might do, for it has much the same qualities as tungsten steel. It would seem probable therefore that the price of molybdenum may rise shortly at the expense of tungsten.

ON New Year's day the principal mining companies at Douglas and Bisbee announced a voluntary increase in wages based on the recent rise in the price of copper. This is both just and sagacious. In the Clifton-Morenci district a sincere effort has been made by a Citizens Mediation Committee to arrange the settlement of the strike affecting the Arizona, Detroit, and Shannon copper companies and their employees. The strike has lasted now for four months. A concession as to higher wages was made by the mine managers, provided the men would surrender their charter of membership in the Western Federation, and this offer was presented by the citizens committee to the executive committee of the miners and through them to a mass meeting. The offer was rejected. It is reported that the American miners were for acceptance, but the Italians voted against it, as also many of the Mexicans, who are in a big majority. The committee of citizens, however, is still hopeful of settling the trouble, believing that the proposal was not thoroughly understood by the miners. We shall be glad to see this effort successful, for it will accomplish two worthy purposes: (1) to give the miners a share in the prosperity caused by 22-cent copper and (2) to help in eliminating an anarchistic organization that has done so much harm in the West and South-west.

MARANON PLACERS is a name familiar to our readers in association with an unsavory mining enterprise in Peru. In April 1914 the promoter, Mr. Raymond McCune, was arrested on the charge of using the mails to defraud the public by the sale of $200,000 worth of stock in the scheme. A number of persons of high standing in Delaware had been lured by Mr. McCune's talk concerning his discovery of "the treasure-house of the Incas." The action taken by the Post-Office department to stop this imposition was most commend-

able, but its later efforts to secure evidence are not nearly so praiseworthy. An inspector, Mr. Harry A. Barber, was sent by the Post Office department to Peru to investigate McCune's alleged prospecting operations. This inspector was accompanied by two official companions, one of whom is versed in placer mining. Thus a considerable sum of public money was spent on what seems to us a wild-goose chase, for, whether McCune sank few or many shafts, and whether he actually found gold at given spots or not, it is impossible to disprove it now, after a lapse of three or four years. If no gold were found by the investigating expedition, he could retort that they had examined the wrong spots. Moreover, most of the holes would now be filled up and overgrown. We consider the whole procedure foreign to the Department's duty in such matters. To stop the use of the mails for impudent circularizing and to warn the public is well within its functions, but if the Department is to undertake the examination of mines it should retain an engineer of high standing and act on his advice, which, in this case, would have prevented a fiasco.

COPPER is making new records. Just before Christmas the British Government signed a contract for the purchase of 135,000,000 pounds of copper in New York at 21 cents per pound, making $28,350,000. This order is to be filled within the ensuing twelve months. We understand that the business was done mainly with the Anaconda Copper Company, although the American Smelting & Refining Company and the Tennessee Copper Company participated. On December 22 the total sales of copper are estimated to have reached 200,000,000 pounds, representing a gross value of over $40,000,000, this being the record for a single day. The war demand for copper is estimated at 750,000,000 pounds per annum. That is in this country only, in the making of munitions for the Allies. Including the Germanic group, the present rate of consumption for use in the War is put at 1,200,000,000 pounds. This represents a little over one-half the total world production in 1913. The average annual consumption of copper in the United States during the five years from 1909 to 1913 inclusive was 365,000 tons. At the present time domestic production is about 900,000 tons. Allowing 400,000 tons for normal domestic requirements and 350,000 tons for normal export, we have an excess production at the present time of about 150,000 tons per annum. As the ordinary rate of increase in the world's consumption of copper is 7%, equal to 70,000 tons per annum, the present output is not so overwhelming. In 1907, when copper reached a price of 25 cents, the world's production increased only 18,610 tons over 1906, the average price in 1907 being 20 as against 19.2 cents per pound in 1906. For the last 15 years the average has been a little over 15 cents. During that period the world's production has increased from 486,500 to 1,100,000 short tons. On the whole, therefore, while the present price is decidedly high, it does not represent a figure so unreasonable as is feared by many mining operators. The main question is as to the proportion of the war consumption that goes permanently out of use; in other words, how much of the copper in shells and cartridges is saved by the belligerents? If saved for future use, it will represent such an increase to the stock of metal as to endanger the market.

Antimony

The average price of antimony in 1913 was 8.73 cents per pound for Cookson's brand, in 1914 it was 10.73 cents, and the present quotation is nearly 40 cents. The War is responsible for this high price. In 1914 China produced 13,313 metric tons, France 5406 tons, and Hungary 859 tons. Large quantities of metal are now required in the making of ammunition and explosives. As the supply from France and Hungary is cut off, as well as the production in Mexico, that from China has to take care of an abnormal demand for war purposes, and the domestic needs of the United States. Imports into this country during a normal period, such as 1913, were 7667 tons of metal or regulus, also 25 tons in ore, and 50 tons in type metal. The production from domestic leady ores in that year was 2204 tons, from imported ore 304 tons, and from old alloys, scrap, etc., 2705 tons. No purely antimonial ores were mined in 1913, according to the U. S. Geological Survey, this being due to low prices and lack of railroad facilities to the mines. The Survey's bulletin on antimony for 1914 is not yet available. For several years the production in this country from domestic ores has been confined to that contained in antimonial lead and small quantities recovered in the electrolytic refining of copper and lead. The antimonial lead is mostly a by-product in the smelting of the precious metals. The high price has led to the search for, development of, and production of antimony from American deposits. At present the Alaskan (Fairbanks), Californian (Inyo and Kern), Idaho (Coeur d'Alene), and Nevada (Humboldt county), deposits are being exploited actively. Several mills are producing concentrate, and smelters are in operation at Los Angeles, San Francisco, and Seattle. The output of the United States in 1915 should show a big increase.

Little has been published on the metallurgy of antimony. The best work on the subject is that by Mr. C. Y. Wang, whose book, however, is a summary from French, Italian, and German publications and reports, as far as the metallurgical data are concerned. The description of the Herrenschmidt processes and appliances plays a disproportionate part in this interesting volume. Without going into details in regard to the claim set forward as to the sublimation treatment applied to antimony ores, it would appear from the facts that the first to obtain soluble oxide (Sb_2O_3) direct from the ores was Mr. Emmanuel Chatillon, of Brioude, in the Haute Loire, France. Prior to his invention or discovery, this product was obtained by subliming the metal and condensing the fume. In 1888 Mr. Chatillon patented his process in France under the title, '*Pour un procédé de*

condensation des vapeurs métalliques,' and from that time forward the principal French and Italian smelters have adopted similar appliances for treating low-grade ores, running from 10 to 35%. This led to a long lawsuit between Mr. Chatillon and Giraud & Cie., Brioude, lasting from 1895 to 1900, when it was decided in favor of the former, but not until his patent had almost expired. In 1898 an Italian company erected a large sublimation plant in Tuscany; this is not described in Mr. Wang's book. He states that dry methods are generally adopted for the extraction of the metal, or of the metal in different combinations, while the proposals for the use of wet processes or of electro-metallurgical methods have not yet found practical application.

The different processes for treating antimony ores may be briefly described as follows: (1) Liquation of rich ores, assaying 40 to 65%, in furnaces or pots for the production of crude antimony, the product being sulphide containing 71.4% antimony. (2) Direct smelting of high-grade stibnite and crude ore in furnaces or pots using iron as a desulphurizing agent, the product being antimony metal. (3) Sublimation process for the treatment of either sulphide or oxide ores, especially adapted to low-grade ores, yielding antimony oxide. (4) Reduction of oxide from the preceding process by smelting with fluxes and carbon, producing 'star' metal.

Crude metal is largely used in the making of fireworks, safety-matches, vulcanizing rubber, etc. Oxide of antimony is used for the manufacture of paints, enamels, in glass and crystal, and the preparation of antimony salts. Antimony metal is used for hard lead, type-metal, anti-friction compounds, and other alloys. It is sold as 'starred' metal, and the market not only demands a product assaying 99%, but also that each slab should have the fern-like crystallized surface known as the 'star,' although this does not indicate that it is chemically pure.

There are several furnace methods of reduction, that shown on the front cover of this issue of our paper being a part of the plant owned by the Chapman Smelting Company, in San Francisco, where smelting is being done by what is commonly called the English method. Here the furnaces and general working conditions are practically the same as those of Hallett & Fry, near London. The process comes under the second of those classified above, the different stages being: the melting of rich ore or crude in a crucible with fluxes and iron, the metal thus obtained being known as 'singles' and containing over 90% antimony, 7 to 8% iron, and 0.3 to 0.5% sulphur. It is poured into conical molds and the metal is detached from the slag—iron sulphide and silica—by hammering. Then four or more 'singles' are broken in pieces and melted in another crucible with a small addition of potash or soda. The metal from this second melt should only contain traces of iron and sulphur, less than 1%. Next the 'doubles' are broken and re-melted in a crucible together with antimony flux or antimony glass, known as 'toppings'; the metal is brought to a bright cherry-red heat and is poured into square molds, care being taken to get enough of the 'toppings' to cover completely the surface of the molten metal and to prevent volatilization, forming the required 'star' under a gentle cooling action. With 30 fires this plant reduces 250 tons of ore yielding about 120 tons of 'star,' 99.5%, per month. Its capacity is limited by the amount of ore obtainable. More labor is required than is commonly supposed; when working full time 32 men are employed. The process is crude yet effective, and considerable physical strength and intelligence are required. Losses in reduction are high, more than in zinc smelting. Blast-furnaces are not satisfactory, and make larger losses. No. 60 plumbago crucibles are used, their life being 20 melts. Coke is the fuel, but oil is used in a new battery of furnaces for the first reduction, as the heat would cause too much loss in volatilization for the subsequent melts, namely, the 'doubling' and 'starring.' The maintenance of a proper temperature throughout the whole treatment plays an important part, as does also the manipulation, which requires skill and experience. On page 61 of this issue is a brief description of the treatment of antimony-gold ore by the caustic soda process, as now used in Rhodesia, and tried some time ago in Australia.

Antimony smelting in the United States has many disadvantages compared with the work done in China in respect to labor, freight, and other charges. It is only the sudden increase of price that has justified the revival of prospecting for antimony, but it is possible that before the War is over the improvement of facilities in regard to transport and reduction of the ores may lay the foundations of a new industry.

Testing for Flotation

In this issue and in the one immediately preceding we have been able to publish an article that must prove of immediate usefulness to a large number of readers. We refer to the detailed description of the apparatus for making flotation tests. For this the profession will, we are confident, be deeply grateful to the authors, Messrs. Oliver C. Ralston and Glenn L. Allen. The senior author, Mr. Ralston, has enriched our columns on several previous occasions. He is assistant metallurgist of the U. S. Bureau of Mines and has been assisting Mr. D. A. Lyon in making the Salt Lake station of the Bureau a centre of useful service to the mining industry. In this article the reader will find not only a detached and unprejudiced description of the various machines designed to ascertain the amenability of ores to the frothing process of flotation, but he will also find a discriminating analysis of the suitability of the individual machines for various experiments and a number of practical suggestions in regard to the manipulation of them. Indeed, we can hardly imagine any information more timely. The article is based on personal experience in the laboratory at Salt Lake City in the testing of a great diversity of ores from the surrounding region. It will be noted that in making such tests the experimenter

must not expect a high percentage of extraction and a high grade concentrate at the same time; in practice that final result is only attained by a repetition of the process in supplementary cells. The authors give the names of the makers of the several machines, with prices, and we have given supplementary information in two notes, realizing that many of our readers will be asking for such information as soon as they have been prompted, by reading the article, to make some tests on their own account. We hope they will. While the process has not the universality of application nor the comprehensiveness of scope that some of its more enthusiastic advocates may claim, it is yet certain that there are few mills in which it cannot play a useful part in one way or another.

Among the hints contained in the article we may draw attention to the convenience of separatory funnels in making preliminary tests, as well as the glass tube designed for testing oils, illustrated by Fig. 19. It will be gratifying to the novice to know that large-scale operations in flotation generally do better than the laboratory experiment indicates. But of all the suggestions proffered the one that impresses us most is the statement that a rational method of devising proper tests must be based on some theory of flotation. Of course. Any metallurgical work, to be productive of result, must be illuminated by sound theory, by a rational conception of the scientific principles involved. It is the absence of sound theory that has retarded the progress of flotation during the 30 years in which the use of oil for concentration has been known and it is the patenting of methods without knowledge of first principles that has produced a pestilential crop of litigation. So far, most of the work done in connection with flotation has proceeded by trial and error, by a crude empiricism unillumined by scientific comprehension of the forces involved, by a succession of fortuitous discoveries the meaning of which has been obscured by the exigencies of litigation. We hope that the publication of this information concerning testing machines will be accompanied by such a study of essential principles as will yield a rich harvest of careful observation and logical theory. On that basis the practical application of the process can be extended confidently.

Last Year's Mining

The preliminary reports of the U. S. Geological Survey provide an excellent summary of mining conditions in 1915. Last week we reproduced the summaries dealing with Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, and South Dakota; this week we give an abstract of the reports on California, Oregon, and Utah; and we reprodnee, almost in full, the account of Alaskan mining. As a rule we care but little for last year's almanac, preferring to look forward, but the Director of the Survey should receive the thanks of the community for giving this interesting information promptly and therefore usefully. The record is superb. In the Western States alone the increased value of the metal production is $130,000,000 as compared with the previous year, and for the whole country the increment of output of the principal metals during the twelve months represents $250,000,000. It is probable that complete statistics will show that 1915 was the most productive year in the mining industry of the United States, the total reaching $2,500,000,000, which is a lordly sum even in these days of war finance. Copper mining, of course, has responded to the intensified demand and the higher price. In 1915 the output of this metal was worth $236,000,000, which is an increase of $83,000,000 over 1914. It is estimated that the production of blister and Lake during the year reached a total of 1,365,500,000 pounds, or 120,000,000 pounds in excess of the largest previous production. The increase over 1914 was 18%. All zinc records have been broken. The output from domestic ores was 425,000 tons, worth $120,000,000 as compared with 343,418 tons, worth $35,000,000, in 1914; thus the increase was 82,000 in tonnage, $85,000,000 in value, and 25% in quantity. As regards the increase in lead, the figures are not so remarkable. The output of pig-lead from domestic ores was 515,000 tons, worth $48,500,000, as compared with 512,794 tons, worth $40,000,000, so that the increase in tonnage was only 2500, but the gain in value was $8,500,000, equivalent to 20% more. Antimonial lead increased from 16,668 to 20,550 tons, the gain representing $2,000,000. In regard to the precious metals, the Survey and the Mint join in estimating an increase of $4,359,300 in gold, principally from Colorado, California, Alaska, Montana, and Idaho, while the silver production has advanced by 4,000,000 ounces, chiefly from Montana, Utah, and Arizona. The increase in the yield of gold brings the total to $98,891,100, as compared with $94,451,800 in 1914. Quicksilver also has seen its best year in 1915, the quantity produced increasing 25%, while the value of the output was more than doubled, owing to the price having averaged higher than at any time in the last 40 years. The estimate is 20,681 flasks of 75 pounds each, worth $1,768,225. In value this is the best since 1881; in quantity it is the best since the year 1912.

In several states the past year was the best on record as regards metal mining. In Arizona, which is first in copper, even the 1913 record has been beaten. California is still at the head of the gold-producing states, with an output of $23,005,800, which is the biggest in 45 years. Colorado comes second with $22,191,200, Alaska third with $16,626,700, and Nevada fourth with $11,314,700. In Montana and Arizona the increased by-production of silver has been noteworthy, but Nevada is still the largest producer, with 13,793,000 ounces, as against Montana's output of 12,690,200 ounces and Utah's output of 11,168,500 ounces. Idaho produced 10,595,300 ounces of silver. In Alaska the intensified production of copper has joined with the yield of gold in making a year more prosperous than even the halcyon period of bonanza alluvial mining in 1906, when both Nome and Fairbanks were at their best. In fine, 1915 was a great year; and 1916 promises to be even better.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Who Owns a Report?

The Editor:

Sir—Your recent editorial on this subject brings forward a question of particular importance to the young engineer in the earlier stages of his professional work, and of great interest and practical significance to the older practitioner. Your request for a general discussion of the question shows a recognition on your part that "all opinions, properly so-called, are stages on the road to truth." In a young profession like ours, the code of ethics is still in the making, and I believe that a thorough discussion of it would be of general benefit. I therefore endorse your hope that there will be a wide response to your invitation.

The problem may be considered both from the legal and from the ethical standpoint. From the legal point of view the ownership of a report would probably be decided by a consideration of the customary practice, and of legal decisions, if such exist; but this phase of the question is better left to the lawyers or those in touch with the authorities, for while most of us think we know what our legal rights are, in many cases a close analysis of our ideas is apt to show them to be based, not so much on an actual knowledge of the law, as on the principles of fair play and justice. From the latter standpoint the question may be stated as follows: should a mining engineer communicate to one client, or use for his benefit, information obtained for and at the expense of another client; and what circumstances, if any, would justify a course of this kind? How far may a client insist on an engineer's secrecy concerning the report? In answering these questions it may be well to first consider the relationship between the engineer and his client.

The circumstances that usually bring the client into touch with the consulting engineer are that the one wishes special information and advice to guide him in the spending of money on a mining property, and the other is in a position to secure and furnish such guidance. An agreement is reached under which the engineer is to furnish the desired information for a money compensation. The relation is contractual, and an element vital to a contract is a mutual understanding between the parties to it; a distinct common intention as to the part each shall play in it. In order to reach a fair decision in the matter it is, therefore, of importance to examine further the mental attitude of the parties to the agreement.

To this end it is pertinent to inquire what the client wants and what he expects to get when he retains an engineer to examine a mine. It may be assumed that he desires a written report containing a description of the property, an appraisal of its value, a statement concerning its probable future, and mention of any facts or conditions that may have a bearing on these subjects. Frequently he desires advice as to the purchase of the property at a particular price. It may further be assumed that he expects to secure the engineer's loyalty to his interests for as long a time as his exclusive knowledge of the property is reasonably of use to him. Also he may expect non-intercourse on the engineer's part with conflicting interests, inasfar as such intercouse might injure his business. He wants the examination and report for the purpose of furthering his pecuniary commitment.

The engineer, in accepting the commission, implies an agreement to furnish, to the best of his ability, the required information and advice as far as it is possible within the limitations of the time and expense allowed. Tacitly he agrees that the quality of his work shall be commensurate with the breadth of his experience.

Without speaking from a legal standpoint, we have in these mutual considerations all the elements that go to make up what is ordinarily meant by an agreement or a contract. One feature of the contract I would especially emphasize: that the client enters into it for the purpose of making money, and that he employs the engineer as a precautionary means of safeguarding his investment. Presumably the engineer is fully aware of this phase of the contract and agrees to it.

Since the report is for the purpose of promoting a matter of business, its value to the client is often dependent on his exclusive possession of its contents. Its confidential features are: first those that are private from their very nature and remain so for a long time, and second those that are private as long as they may affect the client's negotiations for the property, or the other business with which the report may be concerned. In my opinion the former class includes the terms of the proposed deal, the specific advice offered, and perhaps the report itself as a whole, or even the bare fact that a report has been made. All of these may be essentially concerned with the client's private business operations and are only to be given out at his pleasure. The latter class includes geological, metallurgical, statistical, or engineering facts; things that could be as well secured by other equally competent engineers for other clients. They need be regarded as confidential only as long as the

client retains sufficient control of the property to prevent others from searching for them. Possibly they have already become known to others through previous examinations, and are not so very private after all. The dropping of the business, as through the failure to exercise an option, would immediately make the same facts available to the next prospective buyer. What good reason would there be, in a case of this kind for an engineer to deny himself the patronage of a second client who wished him to report on the same mine? In most cases there would be none. But exceptional cases may exist: the engineer may not be informed on all the provisions of the deal; unknown to him there may have been provisions for the renewal of the option, such as would be affected in a way injurious to the client by the divulging of information, even after the expiration of the original option. Obviously, the client is in the better position to pass on this question, and the only way in which the engineer can be safe in letting down the bars of secrecy is to refer the question to him.

The limit of time, within which secrecy should be observed, decreases with the client's interest in the property in a business way. This variation may be judged by direct information from the client himself, by significant events, or by the passage of time. A definite statement from the client to the effect that the property is no longer of interest to him, or permission to make use of the original report for the benefit of a second client, would, of course, be sufficient. A request from a second party for an examination, or the intervention of a later option and examination by another engineer, would at least indicate the lapse of the original client's interest. Under certain circumstances, the spread of information concerning the mine might justify the engineer in considering himself to some extent released from secrecy. For instance, an engineer might be sent to report on a new strike of tungsten ore in a district where its existence had not previously been known to others than his client and the discoverer. In this case it might be of particular interest to the client that the nature of the ore, or even the fact that a deposit of any kind had been found, should be withheld; but certainly after the discovery had become common knowledge, there would be no breach of faith in the engineer speaking of it. Another circumstance that might tend to loosen the bonds of secrecy would be the further development of the mine to such an extent that, practically, it had become a new mine: the later disclosures being such that the earlier report had lost its significance. Still another situation in which the client could hardly claim the exclusive right to a report would be where the mine was first brought to his attention by the examining engineer, but where the option was not exercised. The engineer obviously would be privileged to mention it to another client, although the propriety of exhibiting the first client's report might be questioned.

To summarize the matter, the engineer, in making an examination, may wish to use data secured in making a previous report. His experience and general knowledge, by which his client hopes to profit, were obtained largely in doing work of a confidential nature for others. Some important part of it may have been done in the same district, or perhaps in the same mine, where the examination is to be made; and under circumstances that make it of particular importance to the case in hand; and although of a confidential nature when it was done, perhaps the work might no longer be considered in that light. Possibly it was for these reasons that this particular engineer was chosen for the work. Now then—and here is an important point in my argument—if the client expects to profit by data resulting from the engineer's previous work, the confidential nature of which has lapsed, it seems that as a matter of justice, of common every-day fair-play, he thereby obligates himself to surrender similar information when his interest in it ceases. In deciding when such data are available for second use, the engineer must use tact and commonsense. Facts within his knowledge, or direct permission from the former client, will usually make these data honorably available. If such facts are lacking, and if the former client is thought to be unreasonable, it is best to submit to his wishes; and if the refusal appears to be due to 'pure cussedness,' to abstain from further relations with him. But it should be remembered that the client is in the better position to judge of how his own interest might be affected. It would be better to get along without such data than to be accused of using them to a client's detriment.

The engineer's standard of professional conduct should be high. He should be particularly careful not to permit the possession of valuable information to overshadow his knowledge of the former client's object in securing it. In doubtful cases the test should be, not the letter of the law alone, but that of fairness and regard for the client's interest.

What rules should guide an engineer, in the employ of a company, when writing about the technical details of the work he is doing, or has done, for his employer? I think the answer to this question should be governed by the same principles that control the reply to 'Who Owns a Report?' namely: those of fairness and regard for the employer's interest. There is this difference between the two situations; that where a client depends for protection on the consulting engineer's honesty, and where he would be practically at the mercy of an unscrupulous engineer, with doubtful means of redress in case of a breach of faith; an employer has a much more effective means of enforcing his will over the engineer on his staff. But aside from this phase of the question, no engineer of good judgment should be tactless enough to publish, without his employer's consent, an article that might be considered as bearing on the company's business affairs. Even where the article consisted of a description of technical methods as applied in the company's operations, the product of the engineer's own brain, it would at least be in good taste to first submit it for the employer's approval. I think this would be, in most cases, largely a matter of form, as the engineer

should be able to gauge fairly accurately the limits beyond which he might not go. On the other hand, since most men are reasonable if properly approached, I think it will be only in exceptional cases that the publication of articles on purely technical operations will be denied. A broad-minded employer will surely sympathize with the engineer's desire for such recognition from his fellow engineers as may be secured from writing on technical matters; and, if he gives the matter sufficient thought, will perceive that he, through the medium of the engineer's reading, is receiving the benefit of the technical experience of others. Here, again, we have run the question down to the principle that a fair exchange is no robbery.

J. A. Burgess.

Wonder, Nevada, December 14, 1915.

The Alaska Gold Mines

The Editor:

Sir—In your editorial on the Alaska Gold Mines, in the issue of November 20, you estimate that it will take 18 years to return the capital invested, provided that 5½% is set aside for that purpose annually. And in a recent editorial in the *Engineering and Mining Journal* (one of your contemporaries) it is stated that "A mine with a delimited orebody figured upon as lasting 20 years ought to pay about 9½% gross in order to afford 6% net." As the valuation of these shares has been so much discussed it seems as if an examination of the question from an actuarial standpoint may be of interest.

You evidently arrive at the term of 18 years for redemption of capital at the rate of 5½% annually by dividing 100 by 5½, which gives practically 18; however, you have neglected to take into account the fact that the shareholder who applies a portion of his dividend to redeeming, or amortizing, his capital does not put the money received in his safe-deposit box, but invests it in other securities. At present he can safely invest these sums in Government bonds to net nearly 5½%, and at this rate it will require but 13 years to recoup his capital instead of the 18 of your estimate.

The fact, however, that it will only take 13 years to repay the capital does not interfere with your conclusion that the price of $40 per share seems unreasonably high. Not enough information has been given to allow of an exact valuation of the shares, but the maximum statement of resources seems to be that made by the management that the mines will last for a generation and will produce 8000 tons daily at a profit of 75 cents per ton. The buyer of the shares at $40 is paying at the rate of $30,000,000 for the property (750,000 shares) and if 2,800,000 tons are worked yearly the annual profit will be $2,100,000, or 7% on the $30,000,000. Taking the life of the mine at 30 years and the rate on the sinking-fund for redemption of capital at 4% (to be on the safe side) it works out that the shareholder will receive about 5.25% for his investment, an entirely inadequate return for capital invested, or, speaking more accurately, used for speculating in gold mines. On the basis suggested by you that the shareholder ought to have 10% net on his money, the value of the shares works out at about $24. In view of the fact that a large horse of barren material has eut the profits to 45 cents per ton it would seem as if the price of $24 per share was fully high enough.

Although these problems of valuation of shares are fully understood by most engineers, yet they are not treated with any great detail in the ordinary engineer's pocket-book. The most complete set of tables for a reasonable price is to be found in Hurst's 'Architectural Surveyor's Handbook,' published by Spon & Co., London. This is often bound with Molesworth's 'Pocket Book of Engineering Formulæ.' One of the most recent books on the subject is 'The Mathematical Theory of Investment,' by E. B. Skinner, published by Ginn & Co., at $2.25. On pages 160-163 is found an article on the valuation of mining properties, the general problem being stated as follows: "To find the value of a mine when the rate to be received by the investor differs from the rate at which the redemption fund can be accumulated." The formula for this is:

$$V_n = \frac{R}{\frac{1}{S_n} + i'}$$

where V_n = value of the mine; R = the net annual income; i' the rate of interest the shareholder expects on his investment; i the rate at which the dividends can be re-invested; n, the time to elapse before the mine is exhausted. S_n denotes the amount of an annuity of $1 per annum, payable annually for n years, at the rate i.

John Worden.

Salt Lake City, December 10.

Colorado-Gilpin Gold and Radium

The Editor:

Sir—Noting publication in your Mining Summary columns of December 18 of the notice of organization of the Colorado-Gilpin Gold & Radium Mining Co., in which I am named as consulting engineer, I desire to say that I am not connected with this company and that my name has been used without authority.

Further, I take occasion to disclaim any connection with or responsibility for the prospectus of this company, issued from 1005 Drexel building, Philadelphia. Also, for my own part and on the part of others, I wish to protest against the use in this prospectus of letters bearing no dates and published in such a way that they are calculated to give a false impression of their real significance.

Forbes Rickard.

Denver, December 30, 1915.

Montana has an area of 146,080 square miles, which is over twice that of Missouri. Its population is less than half a million, which is smaller than that of Rhode Island, a territory of less than one-hundredth the size. Montana's output of metals in 1915 was $87,000,000.

Scheelite Mining and Grading

By P. B. McDonald

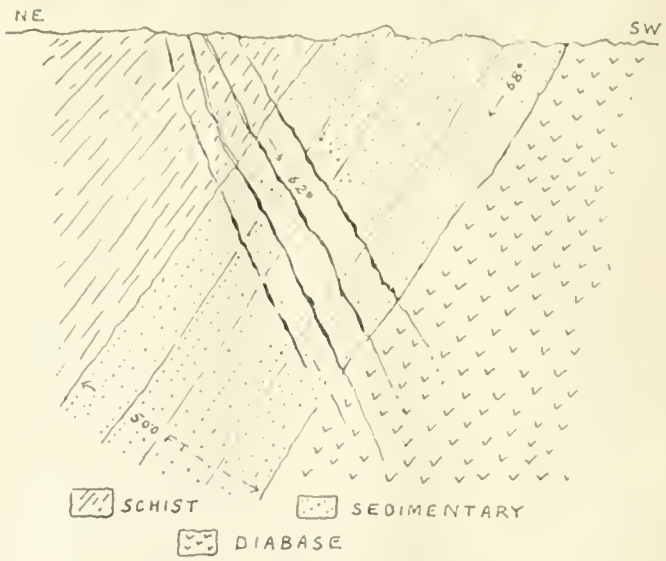
THE Atolia district in southern California, near the line between San Bernardino and Kern counties, has become an important producer of scheelite. Both lode and placer mining are in progress, and lessees are active in many operations of small scale but high profits. Prices of over a dollar per pound for concentrate of 60% WO_3 have stimulated the prospecting and mining of tungsten ores to an unusual degree. But the occurrence of scheelite in California is not confined to the Atolia district.

In the Union Hill gold mine at Grass Valley some scheelite is found associated with the quartz veins, and several shipments of picked ore have been made to a buyer in Colorado, the Wolf Tongue Mining Co. at Nederland in Boulder county, and to Atkins, Kroll & Co. of San Francisco. A. D. Cox, the mine superintendent, has noted that the scheelite is found where the quartz veins traverse a wide sedimentary series of black slate, quartzite, and intermediate phases. The accompanying sketch shows the four narrow veins cutting amphibolite schist at surface, in which no scheelite is noted; but in the 500-ft. thickness of sedimentaries (where the presence of lime may be a factor in the formation of the tungstate of lime) scheelite appears likely to be found liberally. It is not known whether or not there is scheelite in the altered diabase below the sedimentaries, as the mine-workings have not yet reached that depth. It was at first thought that the scheelite would only be found bordering the lenses of quartz, particularly where the vein changed in width. However, later developments in the lowest vein, called the Georgia, have not confirmed this idea, as the scheelite there is found in various parts of the vein.

Mr. Cox's method of grading the scheelite for shipment to the buyer is as follows: The scheelite ore is dried, cobbed, and picked. As is usual with most scheelite ores, what is apparently pure scheelite will be seen, if examined closely, to contain minute stringers of quartz. The specific gravity of chemically pure scheelite (containing 80.5% of WO_3) is 6, that of quartz about $2\frac{1}{2}$. The specific gravity of a piece of apparently pure scheelite was determined by test and found to be 5.42, showing the presence of a small amount of quartz as an impurity.

By proportioning the specific gravities of scheelite and quartz, it was computed that 'pure' scheelite, as found in this mine, contains 84% scheelite and 16% quartz, which means an estimated amount of 67.6% of WO_3. Continuing this computation, it was determined that ore that looked to be $\frac{3}{4}$ (by volume) of 'apparent' scheelite, as judged by the man sorting it, contains 58% of WO_3; that $\frac{1}{2}$ 'apparent' scheelite contains 46% of WO_3; that $\frac{1}{4}$ 'apparent' scheelite contains 35% of WO_3; that $\frac{1}{8}$ 'apparent' scheelite contains 28% of tungstic acid. These figures seem high, but the apparent discrepancy is due to the high specific gravity of scheelite as compared with that of quartz, it being remembered that the sorting is done by volume.

In the first lot that was shipped, the mine estimate of its No. 1 grade as averaging 65% of WO_3 checked closely with the analysis of the buyer, which was 65.1%. The second grade, which was judged at the mine to be 50% of WO_3, proved to be 45.7%. The third grade, estimated at the mine at 25% of WO_3, ran 26.2%. In the sorting for shipment at the Union Hill mine the No. 1 grade is usually made up of apparently pure scheelite; the No. 2



VEINS OF THE UNION HILL MINE.

grade embraces the picked ore between apparently pure scheelite and $\frac{1}{2}$ apparent scheelite by volume. The proportions of the No. 2 grade would thus lie between 46 and 67.6% WO_3; the final percentage is adjudged after looking it over carefully and would be probably nearer to 46 than to 67.6%, rather than the numerical average, because there is usually more ore slightly above 46% than there is slightly below 67.6%. The No. 3 grade is between $\frac{1}{8}$ and $\frac{1}{2}$ apparent scheelite judged by volume. The usual grades shipped are: 1st, 65%; 2nd, 50%; 3rd, 25%.

Mr. Cox's figures on specific gravities and volumes are as follows:

With $\frac{3}{4}$ apparent scheelite by weight, the other $\frac{1}{4}$ assumed to be quartz:

0.75×5.42 (sp. gr. apparent scheelite)	= 4.06
0.25×2.5 (sp. gr. quartz)	= 0.63
Specific gravity of specimen	= 4.69

Proportion of apparent scheelite by weight... $= \frac{4.06}{4.69} = 87\%$

Proportion of $WO_3 = 0.87 \times 0.676$ (percentage of WO_3 in apparent scheelite) ..... $= 58.8\%$

With $\frac{2}{3}$ apparent scheelite by volume (other $\frac{1}{3}$ assumed to be quartz):

0.67×5.42 ..... $= 3.63$
0.33×2.50 ..... $= 0.82$

Sp. gr. specimen ..... $= 4.45$
Proportion apparent scheelite by weight..... $= 81.5\%$
Proportion WO_3 in specimen $= 0.815 \times 0.676$..... $= 55.1\%$

With $\frac{1}{2}$ apparent scheelite by volume, etc.:

0.5×5.42 ..... $= 2.71$
0.5×2.50 ..... $= 1.25$

Sp. gr. specimen ..... $= 3.96$
Proportion apparent scheelite by weight..... $= 68.3\%$
Proportion WO_3 in specimen $= 0.683 \times 0.676$..... $= 46.2\%$
With $\frac{1}{3}$ apparent scheelite the proportion of WO_3..... $= 35\%$
With $\frac{1}{4}$ apparent scheelite the proportion of WO_3..... $= 28\%$
With $\frac{1}{5}$ apparent scheelite the proportion of WO_3..... $= 24\%$
With $\frac{1}{6}$ apparent scheelite the proportion of WO_3..... $= 20.8\%$
With $\frac{1}{8}$ apparent scheelite the proportion of WO_3..... $= 16\%$

Phosphorus, sulphur, and arsenic, although not of consequence in the Union Hill ore, are deleterious impurities in the scheelite because harmful to the steel to which the tungsten is added; one buyer of scheelite imposes a penalty on more than 5% of these elements. The occurrence of scheelite in gold ore raises a question as to the line at which the tungsten becomes more valuable than the gold. If the ore is treated for its gold content, the scheelite slimes so readily, on account of its friability, that it becomes difficult to separate. The most practicable way seems to be to pick the high-grade scheelite and grade it by hand methods. A fine intimate mixture of scheelite and other heavy minerals is difficult to separate; fortunately scheelite is usually found in particles of $\frac{1}{4}$ inch, or over, while the accompanying pyrite is generally less than $\frac{1}{16}$ inch. Cases where scheelite occurs with gold are increasing; they include besides the Union Hill mine, the Wasp No. 2 mine of South Dakota, the Suan Concession in Korea, and several gold mines in New Zealand.

Safety in Using Explosives. In a discussion of the above subject at a meeting of the Chemical, Metallurgical, and Mining Society of South Africa, the points of importance considered by eight members were as follows:

Fractional re-blasting of cut, saliva in detonators, placing the detonator well down the charge, crimping the fuse causing misfires, electric blasting, tearing off paper at ends of cartridge, slitting cartridge longitudinally, frozen explosives, use of cheap fuse of irregular burning speed, deterioration of fuse on storage, rate of burning speed of fuse, tying of fuse with detonator to primer cartridge, primer cartridge at bottom of charge with water tamping, Nowag clip, No. 6 and 8 detonators, weak detonators, damp detonators, saw-dust in detonators, working ends of detonators pointing wrong way, stacking of cases of explosives, excessive coiling of fuse, copper-sheathed tamping-rods, quality of fuse, natives firing holes, cut-out shots, and lig-dyn primers.

Flotation at Humboldt, Arizona

*The flotation process has been introduced into the mill of the Consolidated Arizona Smelting Co., at Humboldt, Arizona, with such success as to increase the concentration of copper 20% above the best work done previously with jigs, tables, and vanners. The ore treated in this mill consists of pyrite and chalcopyrite in a gangue of quartz and schist. Starting with a 3% copper ore, a table concentrate assaying 7% and a table tailing assaying 2.1% are obtained. This table-tailing becomes the flotation-feed, which, after treatment, yields a 14% concentrate and a 0.3% tailing. In September 1915 the mill treated 7173 tons of 2.65% copper ore for a recovery of 90.9% of the copper, 68% of the gold, and 72% of the silver. The ore contains 0.03 oz. gold and 1.3 oz. silver per ton. The ratio of concentration in the mill as a whole was 4:1 and in the flotation department $7\frac{1}{2}$:1. By the old method—with jigs, tables, and vanners—the recovery of copper was only 70%.

The friable copper mineral made a slime that eluded water concentration but is readily amenable to flotation. About 60% of the flotation product is finer than 200 mesh. Wilfley tables are used now only for the rough work, the flotation machines being responsible for the major part of the recovery. The Minerals Separation apparatus is used. Acid is not employed. Nor is the temperature of the pulp raised.

When oxidized ore finds its way to the mill, the extraction suffers. Decomposition products such as iron oxide and magnesium carbonate 'kill' the froth in the flotation-cell.

The total cost of concentration, including coarse crushing and flotation royalty, is slightly over $1 per ton. In September it was $1.03. Exclusive of royalty, the cost of the flotation part of the treatment has been 27 cents per ton during a period of six months. The cost for oil is 2.8c. per pound, on a consumption of a little less than one pound of oil per ton of crude ore. The power consumed by the flotation machine is 32.7 kw. per 24 hours. The improvements made in the metallurgical treatment are due to G. M. Colvocoresses, the general manager, and J. N. D. Gray, the mill superintendent.

Ecuador has an area of 116,000 square miles, being larger than Arizona, and a population of 1,500,000, which is six times that of Arizona. Quito, the capital, situated practically on the Equator, has 60,000 people. Three railroad companies operate, with a total of 360 miles of track. Guayaquil is the leading port of that section of the coast.

*A précis of an article appearing in *Metallurgical & Chemical Engineering*, December 1, 1915.

The Relation of Employer and Employee

By John P. Irish

THE relations of employer and employee have undergone great changes, affecting both classes. Before organized labor was known the workman of exceptional skill and industry commanded not only steady employment, but a premium on his skill, in the form of higher wages than were paid to the less skillful and less industrious. This acted as an incentive to all ambitious workmen to acquire skill in their trade and apply themselves to it with industry. In that time the American mechanic ranked high and advanced rapidly to a position of independence. It was our patriotic boast that a President of the United States had been a tailor, and that U. S. Senators who left a great work in the history of this republic had started in life as skilled cabinet makers, coopers, and harness makers.

All that is so far past that it is forgotten. The labor union system permits no premium on special skill, and it checks industry by limitation of output. Ambition is not merely smothered. It is discredited. Workmen no longer depend upon their skill and quality for employment, but upon the power of the union. They are commanded to work or to cease by the walking delegate or the business agent. The employer is no longer permitted to pick his employees from the members of a union. The business agent does that for him, and orders whom he pleases to work and whom to lie idle. That this power is liable to abuse goes without saying, since the power to favor some members by detailing them to jobs includes the power of the business agent to get a rake-off from the wages of his favorites.

There is no logical nor economic objection to the union organization of labor. The objection runs against its use of power. The unions are extra-legal bodies. They refuse to incorporate and so incur legal obligations, and the right to sue and be sued in civil actions. But they impose fines upon their members and collect them under penalty in denial to the delinquent of the right to work, which is a denial of the right to live, since nature endowed man with wants upon which his life depends and which can be satisfied only by the labor of his hands. Thus denial of his right to work is a sentence to death or dishonesty. This is a power that the State cannot exercise. The government of the United States cannot deny to the weakest of its citizens the right to live by his labor.

The exercise of that power by labor unions, extra legal bodies, with no standing in the courts, and no right to sue or liability to be sued in a civil action, is one of the most alarming manifestations of irresponsible power that the mind can conceive.

One of the avowed principles of labor unions is the right of collective bargaining. The individual workman no longer makes his contract with the employer for wages, hours, and conditions of labor. The contract is made for him by the business agent or other authority of the union. Now a contract, to be just, must be bi-lateral, equal in the responsibility of both its parties for its enforcement and observance. But a contract between a labor union and an employer cannot be enforced by the employer against the union, for the union is a legally irresponsible body. But the union can enforce the contract against the employer, if not by damages against his property in the courts of equity, by calling a strike, putting him under boycott, picketing his property, denying to his customers the right to trade with him, and throwing him into bankruptcy and ruin.

The history of these affairs shows that these things have been done when the employer has not violated any part of the contract, but because he has violated some "union rule" that was not part of the contract and of which he knew nothing.

The public has become accustomed and callous to these things. The courts, under terror of the recall, are cowardly or indifferent to their duty to protect the rights of property and under these circumstances the employer finds himself the powerless victim of union power and vengeance in matters not involved in contract, and which do not concern wages, hours, or conditions of labor.

The streets of Oakland for months have been incumbered by union pickets, sporting a red sash and marching in front of boycotted business houses, and for what reason?

The statement of one case answers for all. A large confectionery store and ice-cream parlor on Broadway is owned and operated by a widow. She has had the same teamsters in her employ for years, paying them the union scale and more. But they were non-union men, and the business agent of the union demanded that they join. They stubbornly refused. Then the business agent demanded of their employer that she make them join or discharge them. She replied that they were free to join or refuse, and she would not discharge them in either event. Therefore the union put her place under boycott and picket, and has in every way annoyed and threatened her customers and injured her business.

Now can you imagine a more defiant and impudent denial of the common right of men than that? Can you imagine a more brutal impairment of the rights of employer and employee alike? Can you imagine anything more repugnant to American citizens, to a lover of liberty, to a believer in our system of government?

Yet it goes on unchecked by the courts, permitted by the municipal government, which asks employers for support, while denying to them the protection of their rights for which they pay taxes. And yet there is no question of hours or wages involved; none of those things called by the unions "the rights of labor."

Surely it is time that the business men of the country organize and demand that labor unions accept legal civil liability or be treated as organizations injurious to the State, and forbidden by law.

*An address before the Oakland branch of the Merchants and Manufacturers' Association.

TWO VIEWS OF THE ALPHA DREDGE OF THE ANDRADA MINES, LTD.

Dredging in Mozambique

THE general manager for the Andrada Mines, Ltd., L. C. de la Malière, has communicated to us the results of the first year's work of the dredge *Alpha*, which is working in the Mozambique territory (Portuguese-East Africa), near the Rhodesian border.

After a trial, the dredge was set to work on February 10, 1914; from then to December 31, 1914, it worked out a surface of 19½ hectares or approximately 48 acres, digging a depth of 14 ft. 8 inches. During this period it treated 1,149,798 cubic yards, yielding gold worth 11,076,239 francs,* equivalent to 18.6 cents per cubic yard. The expenses, including all the general charges, in Mozambique, at Paris, and London were 545,090 francs, excluding amortization. The cost therefore was equivalent to 9.4 cents per cubic yard. The dredge worked 5407 hours, being stopped for repairs during 1912 hours, and for lack of power during 483 hours, equivalent to 2395 hours of lost time. This total is distributed as follows:

	%
For repairs and improvements	39
For lack of power	27
For boulders	20
For moving the dredge and stepping ahead	14

The average working-time per day, counting the loss from lack of power, was 16 hr. 40 minutes. The yardage treated per month averaged 100,000. This was unsatisfactory and was due to shortage of power, caused by the dry season, which lasts nearly three months. The company has erected an auxiliary Diesel oil-engine plant to remedy this defect.

The average expenses per month have been:

	Francs.		Francs.
White men	13,400	Realizing gold	1,000
Natives	1,600	Sundries	1,400
	15,000	General expense	14,000
Material	12,500		
Power	5,500	Total	$10,000 or 49,400

*A franc may be taken at 20 cents U. S.

As this one dredge had to bear all the general expenses, the cost is very high, for it includes all the expenditure in prospecting, to prepare ground for additional dredges.

	Per month.
1 Dredge-master	$200 to 250
3 Winch-men (each)	175 to 200
3 Oilers (each)	150
1 Fitter	200
1 Blacksmith	175
1 Shore-man	125
40 Natives	25 to 75c. per day and food

An average of 3 Americans has been employed, their board being paid by the company. The two features of this dredging operation are:

1. The blasting of the boulders in the buckets, 5625 blastings in 11 months 20 days.

2. The swinging of the boat in a pond about 1000 ft. wide, sometimes 1200 ft. This wide pond helps to render the monthly outputs less irregular, especially in patchy ground. Wear and tear of the principal parts of the dredge was distributed as follows:

Notwithstanding about 8000 blastings, the buckets have not been changed until August 1915, after 19 months work. The lips could serve two months more, 50% of the hoods were cracked or piereed, the bottoms and eyes were in very good shape and will serve for another 18 months, with new lips and hoods.

Pins have lasted 18 months.
Bushings have lasted 9 months.
Screen-plates have lasted 18 months.
Conveyor-belts have lasted 10 months.
Wire cables have lasted 8 months.

The cast-iron idlers, for the conveyor-belt, were all broken in a month's time, on account of boulders. They are now made of cast-steel and resist much better. During the first six months in 1915, the output has been 673,256 francs for a treatment of 781,253 cu. yd., that is, an average of $22,441 per month for 130,209 cu. yd. excavated.

Testing Ores for the Flotation Process—II

By O. C. Ralston and Glenn L. Allen

SEPARATORY FUNNELS. During the past year an article on practice in Mexico[5] mentioned the fact that much of the preliminary testing on the ore was done in separatory funnels, in which the charges of pulp, oil, etc., were shaken, after which the cock at the bottom of the funnel was opened and the tailing run into a second separatory funnel for further flotation tests, the cock being closed in time to catch the froth. The versatility of experiment permissible with the use of such apparatus (Fig. 13) is commendable. Obviously, this arrangement is open to the same objections as is the slide machine except that separatory funnels are simple and inexpensive.

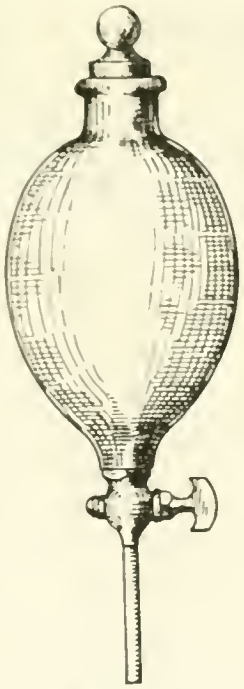


FIG. 13. SEPARATORY FUNNEL.

ELMORE MACHINE. As far as we know, no small test-machine for the Elmore process has come into common use on account of the fact that the pulp must be lifted through a tube corresponding in length to the column of water equivalent to barometric pressure. This makes an awkward laboratory machine. Mr. Hoover (2nd edition, page 98), describes "illustrative" experiments with the pulp in a bottle connected with a water-pump for producing a vacuum, but no quantitative method of this kind has been developed.

Other miscellaneous frothing tests are in the literature but most of them are merely "illustrative." Putting a charge into a soda-water siphon, pumping in air to dissolve the water, and then releasing the charge into a beaker gives nice-looking froth. In some of the lawsuits square glass candy-jars (Fig. 14) with a motor-driven impeller have been used to show flotation phenomena in court. In a recent U. S. Patent (No. 1,155,836) taken out by T. M. Owen, one of the engineers of the Minerals Separation Co., is a sketch of a simple test-machine made of an ordinary 2½-litre acid-bottle. (See Fig. 14A).

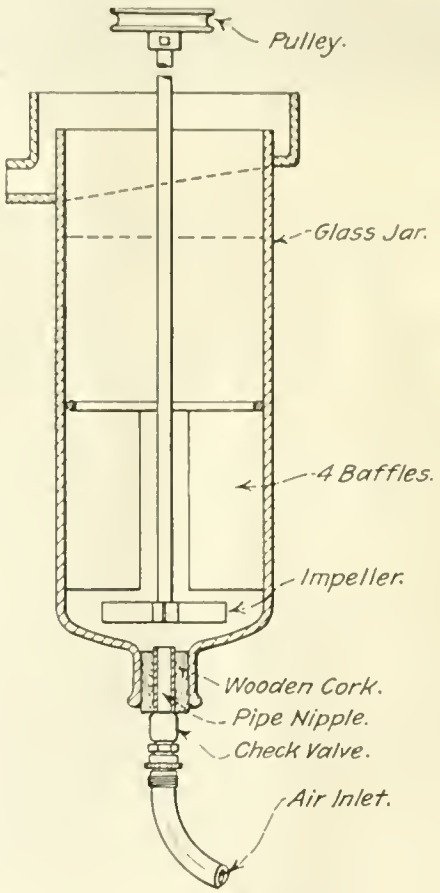

FIG. 14A. OWEN TEST-MACHINE.

This corresponds to the sub-aeration type of machine and is recommended by Mr. Owen for test-work when such a type of machine seems necessary, as in differential flotation. Air is led into the pulp through the stopper in the bottom and beaten into the pulp by the impeller. The four large baffles above the impeller prevent the swirling of the pulp from rising through them, so that there is a quiet zone in the top of the machine where the froth can collect. One great beauty of such a machine is that any froth formed will rise immediately to the discharge. However, we believe that the Janney and Hoover machines are the most useful of the mechanically-agitated type.

PNEUMATIC FLOTATION. Among the different pneumatic machines, as far as we are aequainted, the Callow test-machine is the only one of laboratory size that has

[5]M. & S. P., Vol. CXI, page 122 (July 24, 1915).

been much developed. It is merely the commercial Callow machine reduced in size (see Fig. 15, 16, and 17). Later development in the laboratory of the General Engineering Co., in Salt Lake City, has resulted in the reproduction of the whole plant in miniature (see Fig. 17 and 17a), with Pachuca mixer, roughing-cell, cleaning-cell, vacuum-filter, and sand-pump to return middling to the Pachuca mixer. As seen in the drawing, the

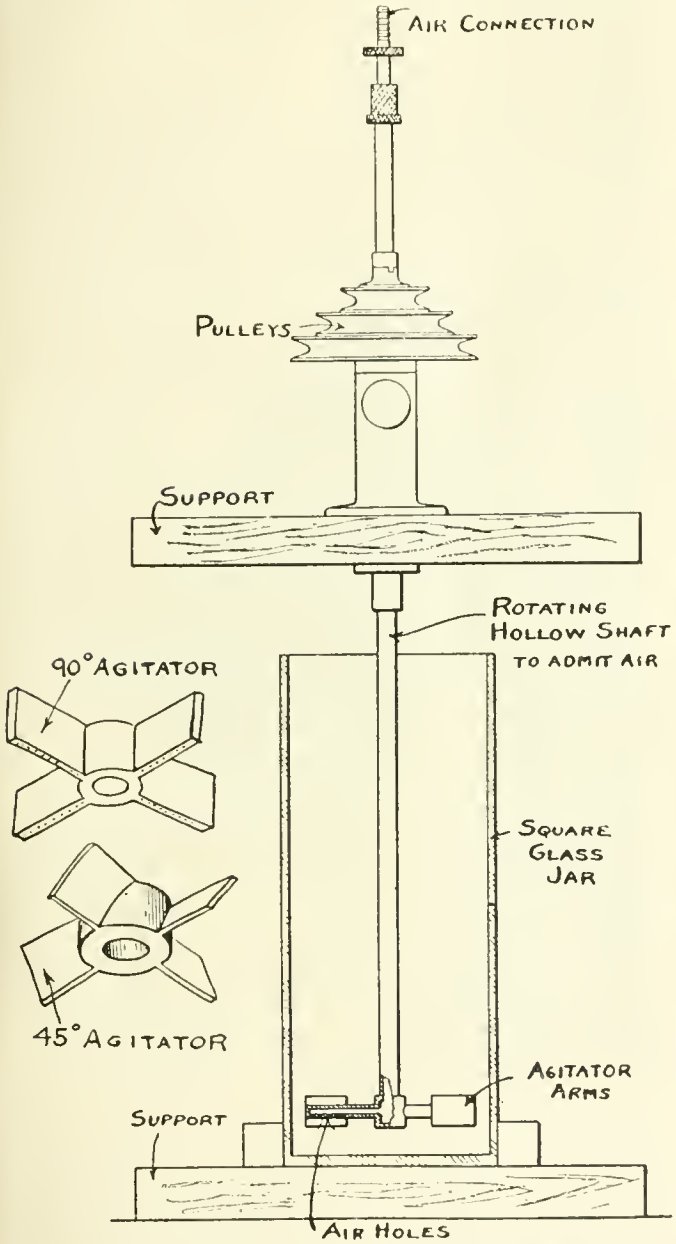

FIG. 14. THE SQUARE GLASS JAR MACHINE.

pulp is mixed well in a Pachuca tank of small size, overflowing into the rougher flotation-cell. The tailing from this rougher goes to a sand-pump and is returned to the Pachuca. The froth is treated in a second and smaller pneumatic-flotation unit, giving a concentrate that overflows into an ordinary laboratory vacuum-filter actuated by a water or aspirating pump. The tailing from the 'cleaner-cell' consists of a middling that likewise flows to the sand-pump and back to the Pachuca.

A novice will have no small difficulty in operating such an installation, as there are a number of things to be kept in operation at the same time. The mixture of ore, water, oil, and any other reagents is fed either into

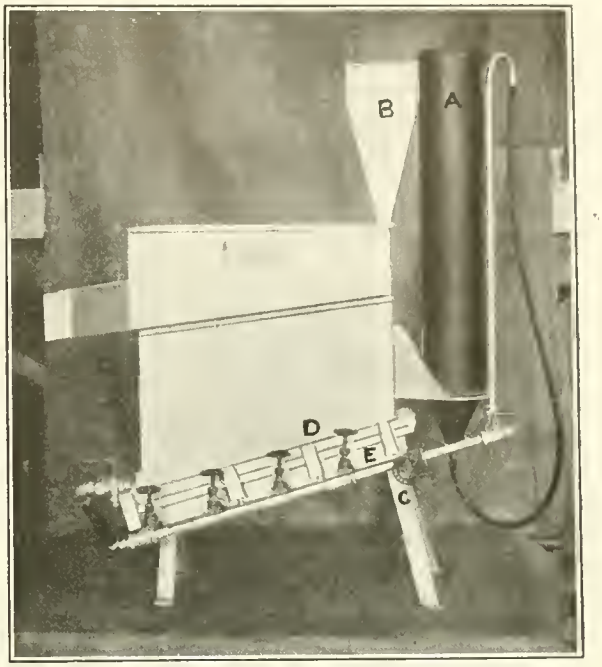

FIG. 17. CALLOW TESTING-MACHINE WITH PACHUCA MIXER.

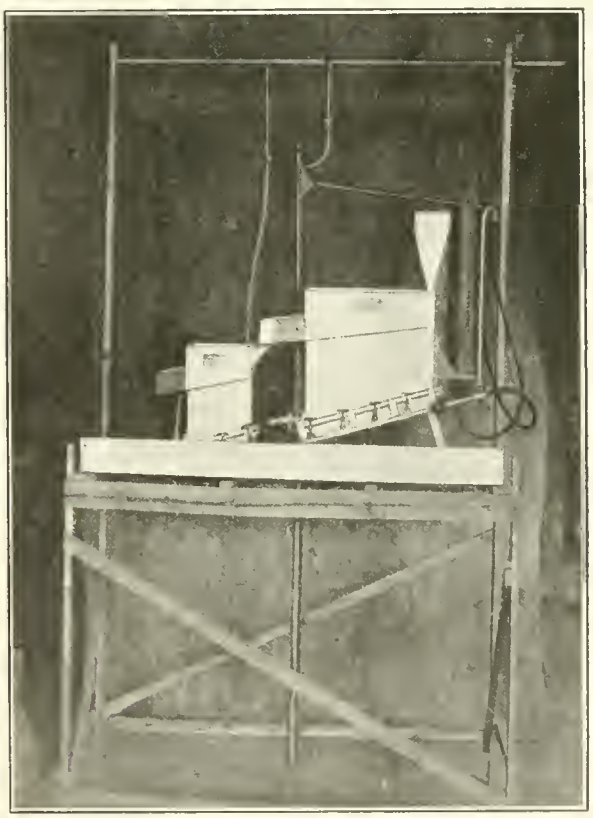

FIG. 17A. CALLOW ROUGHER AND CLEANER IN MINIATURE.

the suction of the sand-pump or into the top of the Pachuca after air has been started into the various machines. The overflow from the Pachuca into the rougher-cell accumulates until a nice froth is coming up and nearly overflowing. Then the tailing-discharge valve on

the rougher is gradually opened and froth allowed to overflow from the cell into the 'cleaner'-cell. It is best to get most of the charge circulating before much concentrate-froth is allowed to overflow, the overflow of froth being controlled by the main air-valves leading to each unit. After the valves into the individual windboxes beneath the machine have been once adjusted they should never be disturbed, and all control of air supplied should be at the valves in the main pipes. When everything is going well, the air pressure in the cleaner can be increased until concentrate-froth is overflowing into the vacuum-filter. A wooden paddle to stir any settled material in the flotation cells is of value, as well as a small jet of water from a rubber hose for washing concentrate along the froth-launders and for beating down froth when occasional too-violent rushes of froth from the cells take place. After a test is complete the pulp should be drained completely from all parts of the machine while the air is still blowing, so that solids will not settle in passages or clog the canvas blanket in the cells. Only practice will allow anyone to get reliable results with this machine. A watch-glass for catching and panning occasional samples of froth is another necessary auxiliary to this equipment. The cost of installing such a set of apparatus is from $100 to $150. At least 1000 grams of ore is required for a test and about 30 minutes to 1 hour is spent. It can be seen that nothing but a finished concentrate and a tailing are obtained. The machine is said to give results closely paralleling those obtained with larger-scale apparatus. A source of supply of compressed air at 3 to 5 lb. per sq. in. is necessary and the main valves on the air-pipe leading to each machine should be some type of needle-valve in order to ensure exact control.

Laboratory Manipulations. Turning from the description of the machines used to the operations on the ore before and after the flotation operation, we have in general the problems of crushing the ore and of drying the froth-concentrate.

As a rule laboratory machinery for the pulverization of ore is of the dry-grinding type, with the exception of small ball-mills that can crush from 1 to 100 lb. charges in the wet. Consequently, most people start with weighed charges of finely-ground dry ore, a known quantity of water, of oil, and of acid or alkali. Our experience has been that most dry-ground ore must be treated in an acidified pulp to get good flotation. Doubtless the surfaces of sulphide particles become somewhat oxidized in, or shortly after, dry grinding and the function of the acid would be to clean the slightly oxidized surfaces. Wet grinding usually does not call for so much acid. In nearly all laboratory work finer grinding than is used in practice seems to be necessary. This may possibly be due to the smaller amounts of froth that are formed. Such small quantities of froth cannot form layers as deep as those made in the large machines. If a big particle of sulphide can be entrained with a number of smaller particles, it can be floated, but with a thin froth the chance of such entrainment would seem to be less. Some experimenters have informed us that they were able to float even as large as 30-mesh material, but our own experience is that 60-mesh material is often hard to float with any chance of getting a high extraction, while the operation is performed with much more ease and expedition when the ore is crushed somewhat finer.

Wet grinding is more desirable, as it parallels conditions in practice, where most of the finer grinding of ore is in Chilean, tube, and other mills. However, wet grinding is harder to manipulate in a small laboratory and requires more time. The dry weight of the feed to the flotation machine must be known; hence a weighed charge of dry ore crushed to about 10-mesh can be introduced into a porcelain or iron pebble-mill for grinding and ground for the length of time found necessary to reduce the pulp to sufficient fineness—15 minutes to 24 hours. The charge can then be poured and washed through a coarse screen (to retain the pebbles) into a bucket and thence into the flotation machine. The oxidation of sulphide surfaces is thus avoided, but separate grinding of each charge, in order to know its exact weight, is rather tedious and requires a number of small mills if many tests are being run, on account of slow speed in grinding. A mill with iron balls rather than pebbles is of greater service. It is possible to introduce the flotation-oil before grinding, to be sure that it will be thoroughly mixed. For thick viscous oils this is highly beneficial, as a ball-mill gives about the best conditions for agitation and mixing. Usually 1 to 2 lb. charges are used and a small laboratory mill of the Abbe type serves well, although a good mill can be made with a 10-inch length of 8-in. iron pipe and two heavy iron caps for the same.

Practice in our laboratory has been standardized to a laboratory-gyratory crushing to 10-mesh, splitting into weighed samples kept in paper bags and reduced to smaller size by either wet or dry grinding as occasion demands.

A short-stemmed tin funnel about 6 inches in diameter with a one-inch opening is found to be about the most convenient means of pouring a charge of ore into a laboratory flotation-machine.

The measuring and testing of flotation-oils in the laboratory has been very inexact in many instances witnessed by us. It is common practice to count the number of drops of oil falling from a small piece of glass tubing. We are using a Mohr pipette of 1 c.c. total capacity for measurement of the amount of oil used in each test. Such a pipette is shown in full size in Fig. 18. It will be seen that this pipette allows measurement of the oil to the nearest 0.01 c.c., which is as close as will ever be desired. If the density of the oil is known, the volume as measured by this method is quickly converted into the weight of oil used.

The testing of oil samples for flotative power is a matter that needs standardizing. It is desirable to classify oils according to flotative power, but just how to do this is not exactly clear. A unit of 'flotativeness' might be established and each oil referred to that unit

in terms of percentage. But it has to be remembered that the best oil for one ore may not prove to be the best oil for another, although two such series of oils might roughly parallel each other. For any given ore, it would be permissible to make such a measurement on a series of oils and group them according to some definite standard. A standard oil might be chosen and the value of a second oil expressed in percentages of the flotative power of the first as determined by using equal quantities of the two oils in tests on an ore under identieal conditions. This

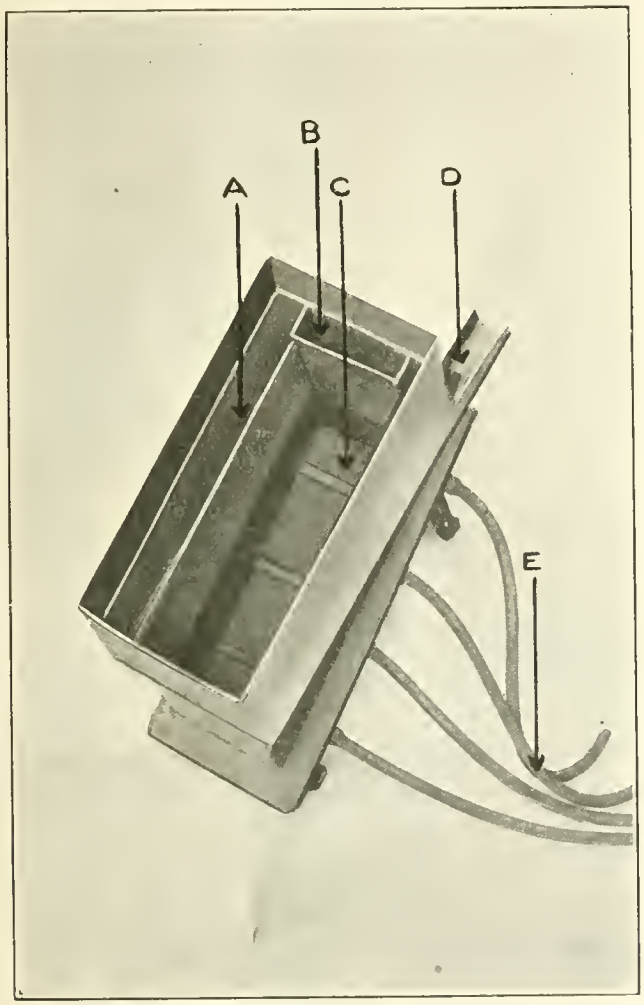

Fig. 15. THE CALLOW CELL.

test could not be fair for the reason that different amounts of two different oils are necessary to accomplish the same results. Further, the conditions of acidity or alkalinity might favor one oil and handicap another. If we measured the amount of oil necessary to give a fixed percentage of extraction the first of the above objections would be satisfied but conditions of acidity or alkalinity could make the test unfair for some oils. Hence the dilemma as to a standardized test of a flotation-oil.

No single test could definitely place an oil in any scheme of classification and nothing can be done but run a series of tests using varying amounts of the oil to be tested and with varying acidity or alkalinity. The temperature of the pulp must be kept constant although it has a minor effect.

Coutts gives about the only directions on oil testing that are to be found in the literature of the subject[6]. He states rightly that the first thing to do with an oil is

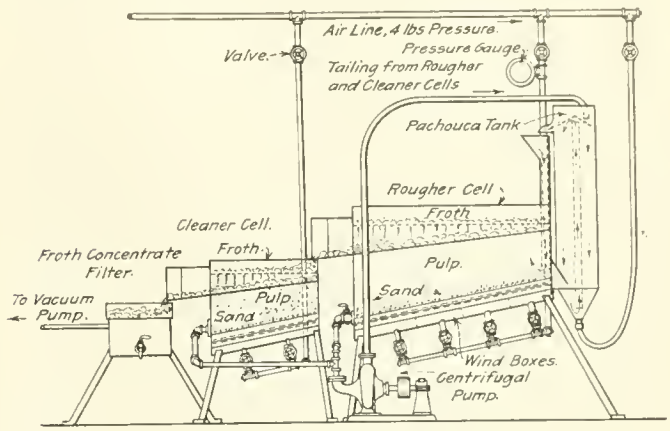

Fig. 16. CALLOW TEST SET.

to measure its density, for future calculations, as it will be measured by volume in the laboratory and must later be reduced to weights. He recommends the use of a burette for measuring the oil, but we favor the Mohr pipette mentioned above. He chooses a standard ore on which all tests are to be run and classifies three different kinds of standard tests: (1) for mixed sulphides, (2) differential separation, and (3) flotation of copper and iron sulphides. He states that oils high in phlanderene have proved best for differential separation of zinc-lead sulphide ores. While this is helpful, he does not state just how the oils are to be classified after the tests have been made.

Much work with oils is needed in order to determine if there are any definite constituents in oils that give them flotation power. Research is also needed in the preparation of oils from the wood, coal, and mineral oils in such a manner that they will have maximum efficiency in flotation. Work on this subject has been initiated in our own laboratory and it is known that several of the larger companies have employed oil chemists to look into such problems. We understand that most excellent work is being done on methods of modifying and reconstructing oils that can be had cheaply. By this we mean

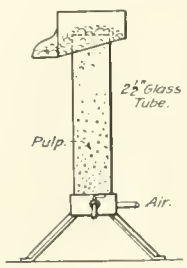

Fig. 19. CALLOW QUALITATIVE TESTER.

Fig. 18. MOHR'S PIPETTE.

more than mere mixing of a good flotation oil with a cheaper non-selective oil. Sulphonating the oils, dissolving them in acids, dissolving modifying substances in the oils, etc., are some of the ideas being tested with varying success. It is on account of all this oil testing

[6]J. Coutts. E. & M. J., Vol. XCIX, page 1079 (1915).

that considerable progress has been made in flotation during the past year, so that now most of the larger companies are using cheaper oils than they were a year ago.

When starting to work with a new ore, there is needed a rapid qualitative method of choosing an oil that seems well adapted to the flotation of the ore in question. Such a scheme is in use in the laboratory of the General Engineering Company in Salt Lake City. Their qualitative tester is designed to test oils for use in the Callow pneumatic flotation cell and consists of a glass tube of about two inches diameter and two feet long. (Fig. 19). This can be set on end and closed at the bottom with a one-hole rubber stopper through which passes a glass tube into a small canvas bag. The small bubbles of air coming through the canvas are similar to those used in large-scale machines and can be observed through the glass walls of the tube. With some pulp in the tube, oils, acids, salts, etc., may be added in very short tests until the proper appearance is obtained. An overflow lip is provided in case it is desired to examine the mineral in the froth. A slight adjustment of the air will provide an ample overflow of froth.

Disposal of the Froth. The handling of the flotation froth in the laboratory finds difficulties which are reflected in practice. It is often very slow to settle and filters with difficulty. A vacuum-filter, connected with a laboratory aspirating pump, is a very convenient method of getting the concentrate out of the froth. A large porcelain Buechner funnel fitted into a filtering flask, as shown in Fig. 7, is used at present in our laboratory. A copper vacuum-filter of much the same type, provided with a porous false bottom of acid-proof wire cloth, resting on a punched plate, is shown in Fig. 17 of the Callow test set. Filter-papers can be laid over the bottom of either of these funnels to collect the concentrates and the vacuum beneath sucks out the water and oil of the froth. Such a filter can be placed under the froth-discharge of a flotation machine so that a fairly dry cake of concentrate is ready for further drying at the end of the flotation test. By loosening the outer rim of the filter-paper and then turning the funnel upside down over a pan, the filter-paper with the concentrate can be dropped into the drying-pan by gently blowing into the stem of the funnel. This is set aside in a warm place to dry and later weighed against a filter-paper tare.

If it is desired, the froth can be collected in a glass beaker or other vessel and allowed to stand over-night. A layer of clear water can then be siphoned off and the thick pulp remaining filtered or dried direct. In some laboratories the froth is dumped onto a shallow pan on a hot plate and the water evaporated. Occasionally such a sample of froth will be left too long, and will be ignited and roasted. We once used a numbered set of shallow pans for such evaporations but prefer filtering before drying the precipitate. A numbered tag is now put in each pan along with the cake.

The products coming from the flotation machine should be watched closely and occasionally panned or examined with the microscope to see what kind of work is being done. This is fairly easy to determine as the sulphides are most of them distinguished easily from the gangue under the microscope, and likewise gangue particles in the froth concentrate can often be distinguished. A microscope is a most useful adjunct in a flotation laboratory or mill.

General Considerations. We have mentioned at various places the relation of the laboratory tests to the large-scale operations and now repeat that in almost every instance the laboratory results are somewhat pessimistic as compared to large-scale work. The reasons are made apparent by the smallness of the machine and the shallower layer of froth often formed under these conditions. Moreover, laboratory operations seem to call for greater amounts of oil, acid, etc., than do the large-scale operations.

Only one of the above machines is adapted to 'roughing' and 'cleaning' operations in a single test. Present-day practice tends toward re-treatment of at least part of the froth in order to make cleaner and higher-grade concentrates. Consequently, it may be desirable to collect enough froth from a series of tests to be re-treated in a 'cleaning' test. Of course, this is provided for in the Callow test set, where only 'cleaned' concentrate is discharged from the machine. It is further found desirable to weigh and analyze some of the successive fractions of the froth being discharged from a flotation machine, as the tailing becomes leaner, and determine at what point it may be desirable to re-treat such froth.

Many reports of flotation test-work with mechanical-agitation machines give the speed of the rotation of the agitating-blades. We have found that it was possible to get much the same work done with quite a variation of speeds, the only effect being to lengthen or shorten the time of treatment. We feel that the importance of this matter has been much exaggerated. Some means of speed-control is necessary and the speed can be adjusted in each case until the froth presents the proper appearance as to depth, size of bubbles, color, etc. Speeding toward the end of a test in order to give a deeper froth with a faint line of concentrate on the very top is often advisable. We recommend adjusting the speed in each test to suit the other conditions, rather than running a series of tests with different speeds. Only in the slide machine, where operation of the impeller must be suspended in order to allow froth to collect, is the speed of much importance. Here we recommend agitation for a definite length of time, and then a period of settling. The effect of variation of speed during a definite length of time may be a considerable variation in the amount of froth collected during the quiet period. Hence we are prejudiced against the use of the slide machine except for oil-testing.

When a good set of conditions has been found for the flotation treatment of an ore, it is best to recover the water from each test to see what effect a closed circuit of the mill-water will have. Some oil and chemicals are thus recovered, cutting down the amounts necessary for

operation. In fact, a carboy or two of the water to be used in the large mill should be used to make certain that no deleterious contamination will ensue from this source. Under these conditions filtration of the concentrate and tailing for recovery of the water is necessary. Such conditions are provided for in the Callow apparatus, above described, and can be applied easily to any of the other machines.

Oil samples for test purposes can be obtained from the various wood-distilling companies now advertising in the technical press, from gas companies and from petroleum-refining companies.

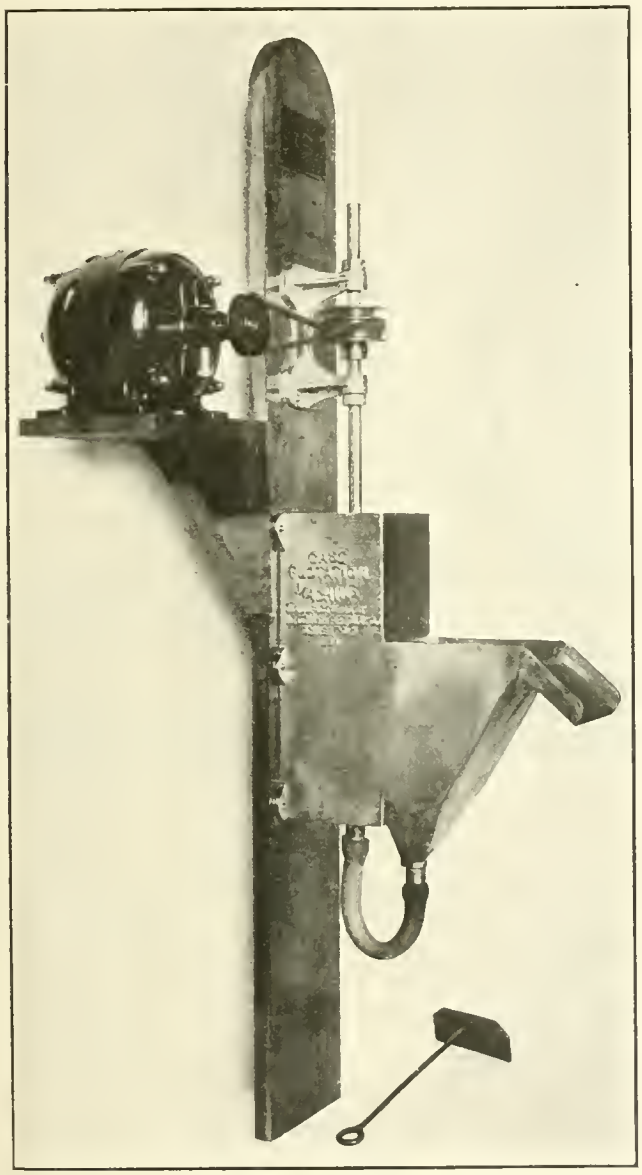

FIG. 20. THE CASE MACHINE.

In attacking refractory ores, there are a number of ingenious things that can be done to the pulp both in and out of the machine. The trouble may be due to deleterious substances, which sometimes can be washed out, rendered harmless by boiling, or by acidifying, or by making alkaline with lime before entering the machine. Occasionally, the ore will not work well under ordinary conditions but will yield beautifully after finer grinding. Sometimes extra reagents are necessary, such as powdered charcoal, modified oil, argol, soap, calcium sulphate, alum, etc. A rational method of devising the proper tests in such cases must be based on some theory of flotation. Colloid chemistry is a branch of knowledge that we believe to be very necessary for such work, as it has facilitated a more intelligent control of our tests and has given wonderful results in a number of instances.

Finally, it is well to be prodigal in the amount of analytical work connected with flotation testing in order to discover interesting differences in gangue-constituents carried into the concentrate, as well as to find the best conditions for leaving out some gangue constituent that is less desirable than the rest. If an experimenter does his own analytical work he can be expected to spend three-fourths of his time analyzing what has been done during the other fourth.

Summarizing the most important points to be tested on a given ore with any given flotation machine, we have:

Method of grinding.
Fineness of grinding.
Kind of frothing agent used.
Amount of frothing agent.
Acidity or alkalinity.
Temperature.
Necessity of preliminary agitation.
Effect of addition-agents in flocculating gangue-slime.

It can be seen that there may be a certain best combination of the above variables that will be entirely missed if a great many tests are not carried out; hence the desirability of doing the testing in a small laboratory-machine where many trials can be made in a short time.

After the best conditions have seemingly been established, they should be further tried in a larger-sized machine before they are incorporated into the general practice of a mill. The test-work on this scale need hardly be described, as, for the most part, it is a question of translation of laboratory results into large-scale operation.

[We have added an illustration of the Case machine, evidently a modified Hoover apparatus, made by the Denver Fire Clay Co.—EDITOR.]

SECONDARY COPPER. As contrasted with lead and zinc, the uses for which copper is principally employed are such that a large percentage of the metal can be eventually recovered and returned to the trade. According to J. P. Dunlop, of the U. S. Geological Survey, "the production of copper from secondary sources in 1913 was equal to about 17% of the refinery output of primary copper in the United States from all sources, or about 22.4% of the primary copper smelted from domestic ores." It is difficult to determine the amount of secondary copper, but apparently 200,000,000 lb. is recovered annually in the United States from material that has been actually used and scrapped. Copper probably shows less depreciation from corrosion, disintegration, burning, abrasive action, etc., than any other metal.

Treatment of Molybdenite Ore in Australia

NEW SOUTH WALES and Queensland are the world's principal sources of molybdenite, and as an embargo has been placed on its export to foreign countries, and as there is a good demand combined with high prices (now $1.50 per pound for 90% product), diligent search is being made for deposits in the United States, while in Arizona and Colorado some ore is extracted. In the PRESS of February 6, 1915, molybdenum was discussed editorially.

The geological department of the New South Wales Department of Mines is preparing a report on molybdenite mining and treatment, and in an advance note one of the staff, E. C. Andrews, makes the following remarks:

Methods in this State are more or less crude even at present, and consist, in the main, of crushing and screening dry. Experiments in water and oil flotation are being carried out in various places in the State, but no large quantities have yet been treated by such processes.

METHODS. (1) Small deposits containing molybdenite flakes of moderate size in quartz. The ore is crushed either by means of bucking-hammers or by hand-rolls. The larger flakes are hand-picked, while the smaller flakes are saved by hand-sieving, the undersize being mainly of the nature of quartz grains.

(2) Large deposits such as at Kingsgate, containing molybdenite and bismuth in a clean gangue of quartz or silicious granite.

The following description is of one of the several plants at Kingsgate, 20 miles east of Glen Innes. The capacity is about 5 tons per day, and the cost of the plant erected was about $5000. Two men and a boy are employed. Ore with an average content of 3% bismuth and molybdenite is hand-fed from a plant to a No. 2 Dodge rock-breaker, and there crushed to pieces about 1-in. diameter. From the crusher the ore passes through two sets of rollers, each set having screens to save the large flakes of molybdenite as over-size. This product is re-rolled to further rednce the quartz. Underneath the second pair of rolls is a shaking-screen. The holes in this shaking-screen are about 1 12-in. diameter. The under-size passes onto a Wilfley table to save the bismuth, the tailing being stored pending probable improvements in treatment, such as some form of oil concentration.

The over-size from the 1 12-in. screen is carried to a third set of rolls, where it is crushed to 1 20-in. gauge and screened. Much of the over-size from this process is cleaned by hand-sieving. The first part of the over-size, however, is re-crushed in rolls set close together, and passed over screens of 1/32-in. mesh. The over-size from this varies from 92 to 95% molybdenite. The under-size is a product rich in molybdenite, but considerably below the required 90% standard.

Some method of water or oil concentration for saving the molybdenite, after treatment of the crushed ore on a table for recovery of the bismuth, is obviously the proper method of treating this ore.

The most satisfactory method known of saving molybdenite up to the present is that practised at Irvinebank in north Queensland.

Some small plants have been made in New South Wales with the idea of concentrating molybdenite ores wet. These, however, have not treated large quantities so far. Of these the plant erected by M. Charles Poulot at Sheehy's wharf, Greenwich, Sydney, presents some interesting features: The ore, after fine-crushing, is pumped to the top of the building into a de-watering tank. Thence the water returns to the pump, while the ore drops into a small centrifugal pump situated below the de-waterer. The centrifugal mixes the pulp with oil fed from a tank by drops. From taps, this oiled mixture is dropped into horizontal shaking-troughs pierced with holes and discharging into boxes filled with water. The molybdenite floats, and is discharged into launders leading by tubes to a screen of 180-mesh, and then dried. The boxes are arranged in four tiers vertically above each other. As soon as a certain amount of pulp has been treated in the upper tier, taps are opened in these boxes and the material, which has sunk to the bottom is led into the horizontal shaking-troughs attached to the second tier, and the whole process is repeated; similarly for No. 3 and 4 tiers of boxes. The process is thus a four-fold one.

[American mining men will be interested to know that at Denver, Colorado, H. E. Wood has a plant for the treatment of molybdenite ores, in which film-flotation is used.—EDITOR.]

Flotation-Tests in Separating Funnel

EFFECT OF ALKALINITY.

100 grams of 200-mesh mill-heads, assaying Au. 0.17, Ag. 29.53, frothed 6 times in 400 cc. mill-water, with 0.44 lb. S. S. oil and 0.44 lb. cresylic acid per ton of ore, at a temperature of 80°.

Test No.	Lime lb. per ton At start.	At end.		—Concentrate-Assay— Gm.	Au	Ag.	—Tailing-Assay— Au.	Ag.	
1.	0.08	0.02	Acid	17.562	0.16	90.0	0.12	16.1	Acid
2.	0.01		Neutral	15.859	0.60	110.6	0.10	12.4	"
3.	0.15		"	15.350	0.82	161.6	0.06	5.1	"
4.	0.25	0.01	Alk.	13.470	1.00	192.1	0.06	4.1	"
5.	0.34	0.02	"	14.20	0.85	184.2	0.06	3.8	"
6.	0.43	0.04	"	15.05	1.00	166.4	0.06	4.2	"
7.	0.70	0.12	"	26.95	0.52	89.3	0.03	6.1	"
8.	1.00	0.25	"	31.55	0.34	60.3	0.09	12.0	"

In separatory-funnel tests, assays of concentrate are much lower than in plant-practice. Tailing-assays are practically the same.

When frothing in mill-water, the best alkalinity, both as regards extraction and grade of concentrate, is from 0.01 to 0.02 lb. per ton of water.

THE U. S. ASSAY OFFICE in New York, for the first time in 18 years, has more gold on hand than it has room for; the overflow has been taken to the sub-treasury vault; the total recently was $235,000,000.

Mining in Alaska in 1915

Advance Statement by U. S. Geological Survey, Compiled by Alfred H. Brooks

GENERAL. The Alaska mining industry as a whole was more prosperous in 1915 than in any previous year. This is indicated by the value of the total mineral output, which is estimated to have been $32,000,000, compared with $19,064,963 for 1914. The highest value for any previous year was in 1906, when Alaska produced $23,378,428 worth of minerals, but this was at a time when the bonanza placers of Fairbanks and Nome were yielding their greatest returns.

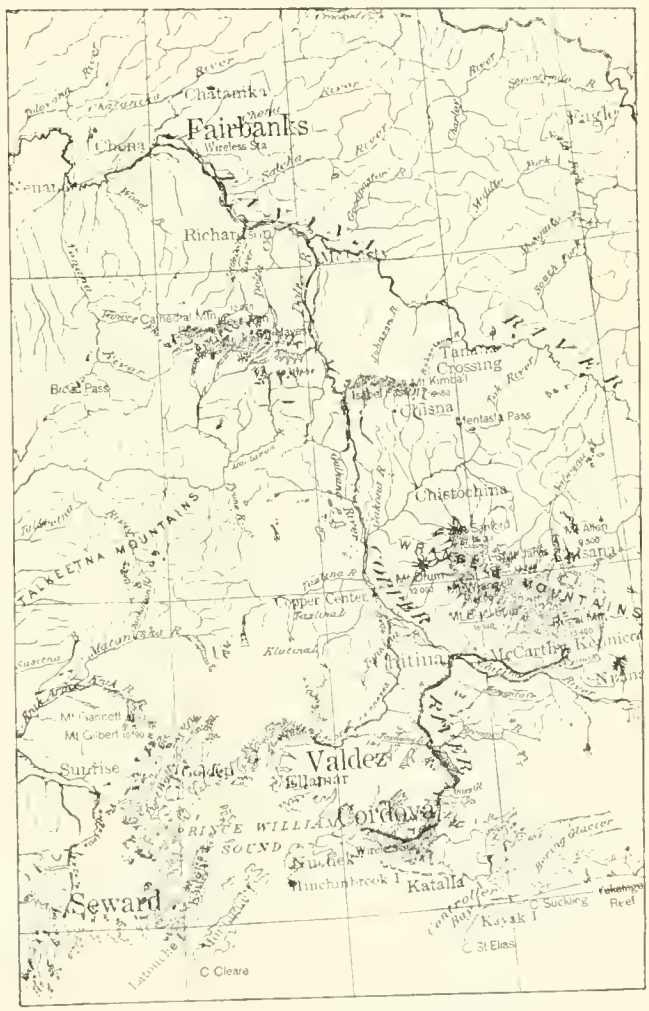
The high value of the mineral output in 1915 was due in large measure to the extraordinary amount of copper that was mined. Preliminary estimates indicate this to be 83,850,000 pounds, valued at $14,400,000. In 1914 21,450,628 lb. of copper was mined, valued at $2,852,934. The gold production also increased in 1915, when the value was about $16,900,000, against $15,626,813 for the output of 1914. This is the largest gold production since 1912, when the output was valued at $17,145,951. As the production of silver is incidental to gold and copper mining, this also increased. It is estimated that $400,000 worth of silver was mined in 1915, against $218,327 worth in 1914.

The output of other minerals, including tin, antimony, marble, gypsum, coal, and petroleum, in 1915 had a value of about $300,000, compared with $222,802 in 1914.

In addition to the productive mining a large amount of dead-work was accomplished during 1915 on properties that made no output. Therefore the abnormally large value of the total mineral production must not be considered as simply a temporary expansion of the mining industry, due to the high price of copper. The developments made during the year give assurance of continued large operations in both copper and gold-lode mining. Placer mining has been less prosperous, for this industry has not yet reacted to the stimulus of the Government railway, which will make available for profitable exploitation large bodies of low-grade gravel. The same is true of the coal-mining industry, which also must await railway transportation.

The first gold mining in Alaska was done in 1880, and since that time gold to the value of about $261,050,000 has been produced. Of this about $186,200,000 has been won from placers. Copper mining began in 1901, and the total copper output of Alaska is now about 217,250,000 lb., valued at $34,150,000. The value of the total silver production to date is about $2,650,000. Coal, petroleum, tin, lead, quicksilver, antimony, marble, gypsum, and other minerals have been produced to the value of about $2,150,000. Therefore, the value of the total mineral production during 36 years of mining in Alaska has been $300,000,000.

GOLD PLACER MINING. The data in hand indicate that the value of placer gold produced in 1915 was $10,500,000, compared with $10,730,000 in 1914. This decrease of output, if borne out by the final figures, is chargeable to the falling off in the output of some of the Yukon camps. On the other hand, the developments in the Tolovana district, where gold was discovered in the autumn of 1914, indicate that this will become of some importance.



PART OF CENTRAL AND SOUTH-EASTERN ALASKA.

About 42 dredges were operated in Alaska during 1915, the same number as in 1914. From the information at hand it appears, however, that the value of the gold recovered by dredges was less than $2,000,000 in 1915, compared with $2,350,000 in 1914. This decrease is chargeable to the Seward Peninsula districts, where about 37 of the dredges are at work. There can be no question that this decrease of dredge output is but a temporary check to the industry as a whole and is due to

certain local conditions. Several new dredges will be operated in 1916.

Gold-Lode Mining. About 23 gold lode mines were operated on a productive basis in 1915, compared with 28 in 1914. On the other hand, the value of their output has increased from $1,863,028 in 1914 to about $6,200,000 in 1915. This increase is to be credited to the Juneau district, where large developments were continued throughout the year. There can be no question that the gold lode output will increase at a rapid rate. This will be due not only to large-scale operations in southeastern Alaska, but also to the encouragement given to lode mining by the railway under construction from Seward to Fairbanks.

Copper. The tremendous increase in copper output during 1915 has already been noted. Nearly four times as much copper was produced as in the previous year, and the value was nearly five times as much. The copper was taken from 14 mines, of which seven were in the Ketchikan district, four on Prince William Sound, and three in the Chitina district. Though the high price of copper led to the re-opening of some of the smaller mines in the Coast region, yet it should be noted that the increased output was possible only because of the large developments that have been under way for several years. The advance of the Alaska copper-mining industry during the year may therefore be said to have been a normal development of the industry. It is of course true, however, that if it had not been for the high price of the metal, the output would have been considerably less. It augurs well for the future of the industry that the Alaska copper mines are now sufficiently developed to produce so large a tonnage.

Tin. It is estimated that about 200 tons of stream-tin was produced in Alaska during 1915. Much the larger part of the tin came from the York district of Seward Peninsula. Here one dredge was operated throughout the season on Buck creek. A new dredge was installed on the same creek during the summer and operated for a part of the season. No returns have yet been received from the two dredges operated in 1914 on the Anikovik river, in the same district. These two are working on placers carrying both tin and gold. Developments were continued on the Lost River lode-tin mine, and there was also some prospecting of other lode-tin deposits. There was, however, no production of lode-tin.

The only other tin mining in Alaska during 1915 was done in the Hot Springs district of the lower Tanana basin. Here considerable tin is recovered incidental to gold-placer mining.

Antimony. The high price of antimony in 1915 led to the mining of over 800 tons of stibnite ore in Alaska. Nearly 700 tons of this output came from the Fairbanks district, and the rest from Seward Peninsula. It is difficult to obtain any exact valuation of the stibnite ore shipped from Alaska. The evidence in hand indicates that the producer received from $1.25 to $1.75 per unit of stibnite. It is reasonable to estimate that the Alaska shipments sold for $85 per ton in San Francisco. This indicates a value of about $70,000 for the total shipments made in 1915.

Four antimony properties were operated in the Fairbanks district during 1915: the Scratford, in the Treasure Creek basin; the Stibnite, in the Eva Creek basin; the Gilmer, in the Vault Creek basin; and the Chatham Creek mine. All the operations were on a small scale. The mining consisted chiefly of making open-cuts and digging out the ore, which occurs in shoots, kidneys, and irregular masses along zones of fissuring. Most of the ore was broken and hand sorted, and no ore of less than 50% antimony was shipped. The average content of the ore was probably 58%. Considerable prospecting was also done on a number of other stibnite lodes in the Fairbanks district.

The ore was hauled to the railway by wagons and then sent by rail to Fairbanks and over the all-water route to San Francisco. The transportation companies offered a low freight-rate to encourage the new industry.

Developments were continued on the Sliscoviteh mine, in the Nome district. The ore from this property carries some gold, and the mine has been worked for gold. In 1915, however, the energies of the operators were directed toward getting out stibnite ore. Some stibnite was also mined at the Hed & Strand property, a few miles north of the Sliscoviteh mine. The total ore shipped from Nome is reported to be 132 tons, but there is reason to believe that a considerably greater quantity was mined.

Stibnite is not an uncommon mineral in Alaska. The recent demand for antimony has led to the prospecting of a number of stibnite deposits within the Territory. Such work is reported in the Kantishna district, on Prince William Sound, and on Kenai Peninsula.

Here follows a review by districts.

Southeastern Alaska. About 12 gold-lode mines and 4 copper mines were operated in southeastern Alaska during 1915. Preliminary estimates indicate that the gold production of this region, including the output of the placer mines in the Porcupine district, had a value of about $5,500,000. The estimated copper production from this field, all of which came from the Ketchikan district, was 4,500,000 lb., valued at about $800,000.

The Rush & Brown was the only copper mine operated in the Ketchikan district throughout the year. Operations were resumed at the Ht. Mamie, and Mount Andrew mines in the spring and continued on a large scale for the rest of the year. Work was resumed on the Jumbo mine early in summer, and the mine was again put on a productive basis. Some ore was shipped from the Goodro and Cymru mines, and developments continued on the Big Harbor and on other properties. The Ready Bullion, Dutton, and Valparaiso gold-quartz mines were operated, and some output was also made from the Gold Standard, Googoo, and Snowdrift claims. Marble quarrying continued in the Ketchikan district, as in previous years.

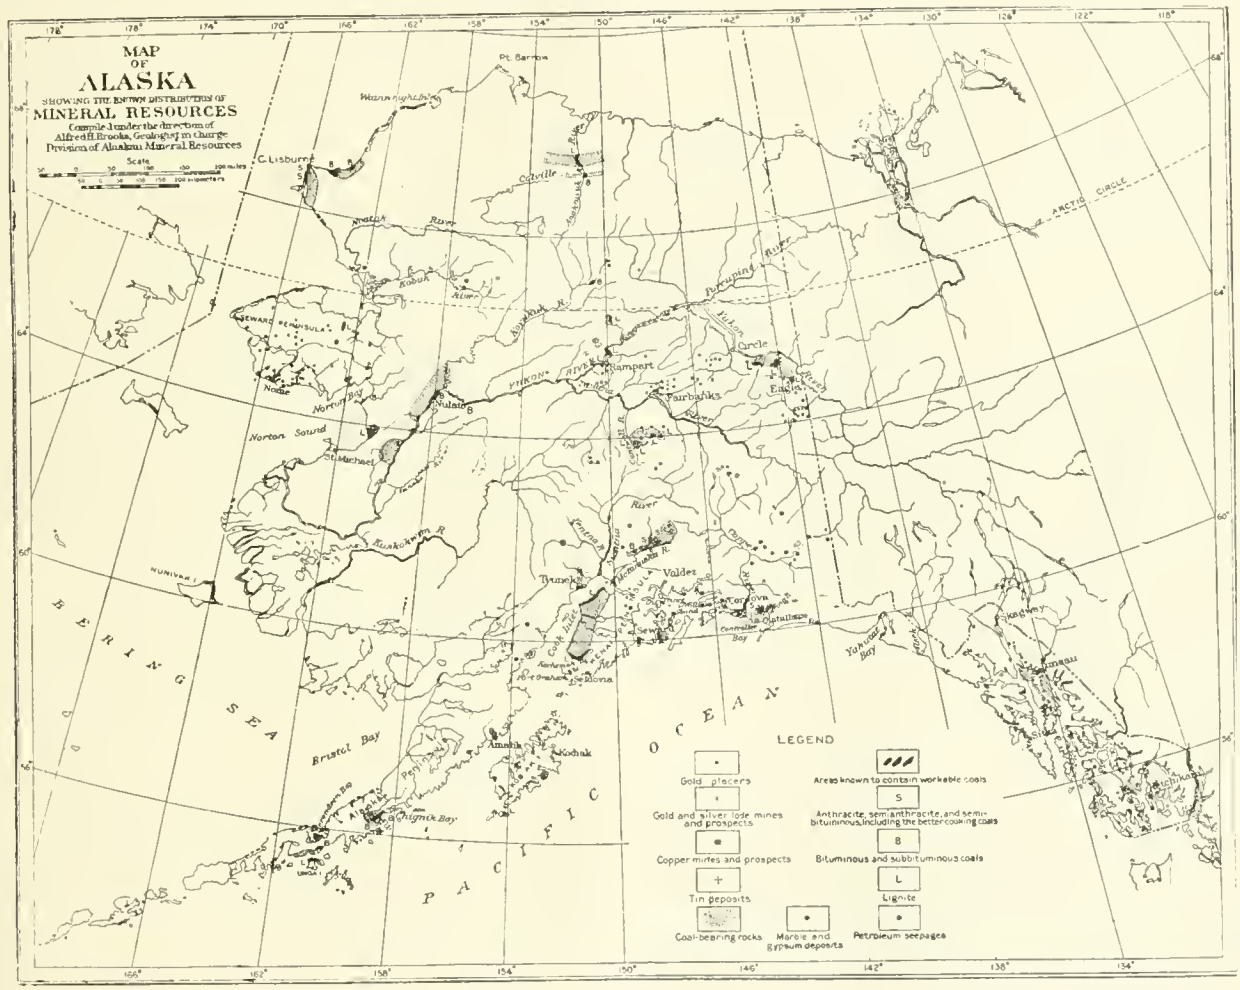
Considerable work was done on both copper and silver-

lead properties in the Wrangell district. Some shipments of barite were made from a deposit near Wrangell.

In the Juneau district the four mines of the Treadwell group were operated on the same scale as last year. An accident to the central hoist curtailed the output for several weeks during the summer. The construction of 30 additional stamps to the Ready Bullion mill is under way. A mill having a daily capacity of about 6000 tons was completed in February at the Alaska-Gastineau mine and operated for the rest of the year. Power is furnished by a hydro-electric plant on Salmon creek. Another plant, the Annex power project, is under construction on Juneau and at the Enterprise, on Limestone Inlet, south of Juneau.

In the Berners Bay region the Jualin mine was productive during the year, and the installation of a new power-house was nearly completed. Hydro-electric power is to be used, supplemented by an oil-burning plant. A group of claims, including the old Kensington, Bear, and Comet mines, in the Berners Bay region, has been consolidated, and the installation of equipment was begun.

The old Funter's Bay mine, on Admiralty island, has been re-opened and was operated on a productive basis in



Taku Arm. The mill of the Alaska-Juneau was operated during the year. The construction of a larger mill —a part of the original plan for the equipment of this property—has been begun. This mill includes four units, each having a daily capacity of 2000 tons. Hydro-electric power is to be used, supplemented by an oil-burning plant. Developments were continued on the properties of the Alaska Gold Belt, Alaska Taku, and Alaska Treasure mining companies, all of which are near Juneau.

The Eagle River mine was operated during the year, and a little productive mining was also done on the Peterson properties. Developments were continued on the Yankee and Montana and other properties north of

1915. The plant of the Chicagof mine, in the Sitka district, was enlarged and the mine was operated throughout the year. Gypsum mining continued at Iyoukeen Cove, on Chicagof island.

Three hydraulic plants were operated in the Porcupine placer district. In the Yakataga district beach mining continued and one hydraulic plant was operated.

Copper River. The enormous output of copper from the Bonanza and Jumbo mines, in the Chitina district, overshadowed all other operations. The adjacent Mother Lode mine was, however, also operated throughout the year. Its actual shipments are as yet limited to the winter season, as the ore is sledded to the railway, a distance of 14 miles. Ore shipments from this district were

interrupted for several weeks during the summer on account of the burning of several railway bridges. Work was continued on a number of other copper properties, but they made no output and details regarding development are yet lacking. The Nizina placer district had a prosperous season. Five hydraulic mines were operated, in addition to some smaller plants. Some placer mining was also done in the Bremner River region, and, so far as now known, placer mining was continued in the Chistochina district on about the same scale as in previous years.

Prince William Sound. The operation of four or five copper mines and four gold mines constituted the principal mining activity of the year in this region. The value of the total product was about $1,400,000, against $1,198,742 in 1914. The Ellamar copper mine was operated on about the same scale as in the past. Operations were also resumed in 1915 at the Three Friends, and copper ore was shipped. The McIntosh mine, on Fidalgo bay, made some copper production, and it is reported that some ore was taken at the nearby Dickey mine, although no shipments were made. Large operations were continued at the Beatson copper mine, on Latouche island. The tram connecting the Midas copper mine with Port Valdez was completed in October, and since that time productive mining has been undertaken. In addition to the productive copper mines noted above, there were developments on many other properties.

The Granite mine, at Port Wells, was the largest gold producer on the Sound in 1915. In the Valdez district the Ramsay & Rutherford mill was operated during the summer, and underground work was continued. The same is true of the Gold King, where the mill was, however, operated for only about a month. At the Cliff mine another vein was found, and the mill was run intermittently during the summer. In the aggregate much other work was done during the year on the gold veins of Prince William Sound, but these operations are too numerous to be listed here.

Kenai Peninsula and Susitna Region. The productive mining region that will be rendered accessible from Seward by the Government railway now under construction includes the gold lode and placer mines of Kenai peninsula, the Willow Creek lode district, the Yentna placer district, and the placers of Valdez creek. Latent mineral wealth is also found in the high-grade coals of the Matanuska fields and the lodes reported to occur in the Broad Pass region. This province has naturally been the scene of much mining activity during the season of 1915. While the large developments planned have not yet reached a productive stage, the preliminary estimates indicate that this field produced nearly $500,000 worth of gold in 1915, which is about $100,000 more than the value of the output for 1914.

In the Kenai peninsula there was much more placer mining than in any previous year. Among the important operations was the installation of a dredge on Sixmile creek. Much work was done on the auriferous lodes of the peninsula, but it was chiefly prospecting and dead work, though incidentally several properties produced some gold. In the Willow Creek district three lode mines were operated during the open season, and developments were continued on several other properties. The hydraulic plant on Valdez creek was operated, and placer mining in the Yentna district continued on about the same scale as in 1914.

Southwestern Alaska. There were no important developments in southwestern Alaska. Development work was continued on the copper-lode claims in the Iliamna region. Some work was done at the Aniak lode mine, on Kodiak island. Beach mining continued as in the past on Kodiak and Popof islands.

The Yukon. The Alaska camps of the Yukon basin are believed to have produced gold to the value of $7,300,000 in 1915, against $7,795,421 in 1914. The value of the output of the Fairbanks district was about the same in 1915 as in 1914, that is, $2,725,000. Preliminary estimates indicate that the gold output of the Ruby and Hot Springs districts was less in 1915 than in 1914. On the other hand, the Circle gold output was greater in 1915 than in the previous year.

No new placers were discovered in the Fairbanks district in 1915. The largest gold production, as in previous years, was from the mines of Cleary, Ester, Goldstream, Fairbanks, and Dome creeks, and their tributaries, this order being about the relative value of the output from each creek. One dredge was operated on Fairbanks creek. On Goldstream creek and its tributaries, Pedro, Gilmore, and Fairbanks creeks, mining was done chiefly by the use of the steam-scraper, which has been found an economical method of handling gravel. Most of the other large operations in the district are those of deep mining—a method that is becoming increasingly expensive, because of the increasing price of the wood used as fuel.

Of the $2,450,000 worth of gold recovered from the Fairbanks placers in 1915 about $50,000 was taken out during the winter. The most extensive winter operations were those in the Chatanika flats. About 115 placer mines were operated at Fairbanks during the summer, employing 1200 men.

Little progress was made in the development of gold lodes in the Fairbanks district during 1915. Most of the lode miners have decided to await railway communication before embarking in any new ventures, because the present operating costs are prohibitive. In spite of these conditions, the value of the lode-gold production was about $250,000, or nearly the same as in 1914.

The most productive gold-lode mines of the district are the Rhoads & Hall, operated until September, and the Crites & Feldman, operated throughout the year. In the autumn a 5-stamp mill was installed on the Gilmore-Stevens property, on Fairbanks creek. This mill was operated from about the first of September to the end of the year. Gold ore was also produced from a number of other properties and treated in one of the many mills of the district. The production of nearly 700 tons of anti-

mony ore from four properties in the Fairbanks district has already been noted. It is reported that a vein carrying tungsten ore (scheelite) was found near the head of Gilmore creek in the autumn of 1915.

The newly discovered Tolovana district lies about 50 miles north-west of Fairbanks. It is connected with Olnes, a station on the Tanana Valley railroad, by a winter road about 55 miles long. This road has also been used for pack-horses in summer. Another route of access is by launch up Tolovana river to a log-jam, around which a tram has been built. The distance to the log-jam by the windings of the river from the Tanana is about 200 miles. Above the log-jam a launch can be used for another 20 miles to the head of navigation; thence a wagon can go up the river-bars to Livengood, the principal settlement of the district, where are a post-office and a wireless station.

The gold placers of the district that have actually been developed are nearly all on Livengood creek and its tributaries. Of these the richest deposits are the so-called 'bench gravels,' which have been traced as a deep channel for two or three miles. Probably a dozen shafts have been sunk to bedrock on this deep channel, which lies on the north side of the creek. At Discovery claim the deep placers are about 100 ft. below the surface. The overburden thickens rapidly down-stream and becomes thinner up-stream.

Placer gold has also been found in the gravel of Livengood creek. These deposits are said to be from 10 to 20 ft. deep and to carry some gold, but they have not been developed. Besides the work on the deep placers, mining has also been done in the comparatively shallow gravels of several tributaries of Livengood creek and on Olive creek, in the same district. There were probably in all not over half-a-dozen plants installed in time for operation during the summer of 1915. These produced gold to the value of about $60,000. There was, however, a good deal of prospecting, and the results were encouraging. Late in the summer some promising prospects were found on the south fork of Mike Hess creek and its tributaries.

About half of the gold output of the Ruby district came from the mines on Long creek and its tributaries. This locality contained not only the largest producers, but also the greatest number of plants. The output was somewhat curtailed by a dispute between the operators and miners in midsummer, when the 8-hour law for all underground mine-workers went into effect. Poorman creek and its tributaries was the second largest producer of gold in 1915. Placer mining was also done on Birch, Trail, Tamarack, Spruce, and Flat creeks. Extensive prospecting was done on Greenstone creek, where a dredge is to be installed in 1916.

The value of the gold produced in the Iditarod district in 1915 is estimated at $2,050,000, or practically the same as in 1914. In all, 31 placer mines were operated, employing from 350 to 400 men. Two dredges, one on Flat creek and one on Otter creek, were in operation throughout the season. One drag-line excavator, the first to be used for placer mining in Alaska, was installed on Willow creek during the summer. The principal centres of gold production were at Discovery claim on Otter creek, on the upper part of Flat creek, and at the heads of Happy and Chicken creeks.

THE SEWARD PENINSULA.

Complete returns have not yet been received from the Circle district, but the data at hand indicate a larger production than in 1914. The installation and operation of a dredge on Mastodon creek formed the most important event of the season. A number of hydraulic plants were also operated, as well as a larger number of smaller placer mines.

In the Hot Springs district about 30 placer mines, em-

ploying 300 men, were in operation during 1915. The largest plants were near the mouth of Woodchopper creek, where some rich placers were developed. The value of the gold output is estimated to be between $500,000 and $600,000. There was also some production of stream tin incidental to gold mining.

Preliminary estimates indicate that gold to the value of about $135,000 was recovered from the Chisana district. The value of the output in 1914 was $250,000. About 25 placer mines were worked during the summer and the principal operations were on Bonanza creek. New discoveries of placer gold are reported to have been made on Dry gulch, a tributary of Johnson creek.

The Koyukuk district is estimated to have produced gold to the value of nearly $300,000 in 1915, compared with $260,000 in 1914. A large part of this was taken out of one or two mines on Hammond river as a result of winter deep mining. The next largest producers were the mines on Nolan creek. A new discovery of placer gold was made on Jay creek, a tributary of Wild creek, and here considerable gold was mined.

It is estimated that the value of the gold output of the Innoko district in 1915 is $190,000, or about the same as that of 1914. About 22 mines were operated in the winter and 38 in the summer. Yankee creek was the largest producer, and here two steam-scraping plants were installed. The second largest producer was Spruce creek, and mining was also done on Little, Ganes, Ophir, and Cripple creeks.

No important developments are reported from the other Yukon districts. The value of the gold output of the Fortymile, Eagle, Rampart, and other smaller districts was probably about the same in 1915 as in 1914. In the Kantishna district some work was done on gold and stibnite bearing veins.

The Wade Hampton placer district is situated on the lower Yukon, and Marshall is the name of the recording office. Placer gold was first discovered in the district in 1912 on Wilson creek. In 1915 gold placers were also found on Willow creek, in this district. Four mines were operated during the summer, and some high values were reported. Some prospective dredging ground was tested on Elephant creek with a hand-churn drill, with results that appear to have justified the installation of a power-drill. Some work was done on an auriferous quartz vein on Willow creek, and a sample was shipped for a mill-test.

Kuskokwim. Placer mining was carried on during 1915 in the Candle Creek, Aniak-Kwethluk, and Goodnews Bay districts. The value of the total production is estimated at about $110,000. At Candle Creek a hydraulic plant was installed and operated during the later part of the season. About 40 men were engaged in mining in the Aniak-Kwethluk district. Most of the gold from this district was taken from the placers of Canyon creek. About a dozen men were engaged in placer mining in the Goodnews Bay district.

Seward Peninsula. It is estimated that the Seward Peninsula mines produced gold to the value of $2,900,000 in 1915, against $2,700,000 in 1915. About 37 dredges were operated in 1915, against 39 in 1914. It appears that the dredge production, for which data are not yet complete, decreased much more than is accounted for by the smaller number of dredges. The reason for this decrease is not clear, but it is probably in part due to the fact that as yet there has been but little attempt made to dredge the placers that require artificial thawing. This is in contrast to the operation of the dredges in the Yukon basin, which are practically all on ground that is permanently frozen.

The data available indicate that about $1,500,000 worth of gold was taken from the region immediately tributary to Nome and about $700,000 from the Council district. The other districts, named in order of the value of their output, are Solomon, Kougarok, Fairhaven, and Port Clarence. One of the most important features of the year's operations was a marked revival of underground mining during the winter. It is estimated that about 36 deep mines were operated near Nome in the winter of 1914-15. There was also a little deep winter mining in other districts of the peninsula. The value of the gold produced in this winter work was probably about $300,000. Besides the dredging and deep mining, there were many large open-cut operations, some with the use of hydraulic methods. There were also more small operations than in the previous year, and a good deal of mining on the present beach.

The continuation of stream-tin mining and of lode-tin development in the York district has already been referred to. It has also been noted that antimony ore was mined and shipped from two properties in the Nome River basin. There was considerable prospecting of auriferous lodes in this district, but so far as learned no gold was produced from this source.

Northwestern Alaska. No important developments are reported from the Kobuk basin. Placer mining continued in a small way on Squirrel river and Dahl creek. No returns of production have yet been received, but it is probable that the value of the gold output was about the same as that of 1914, namely, $33,000. The discovery of the petroleum seepage near Wainwright inlet has already been noted.

The San Francisco Mint reports the following transactions, bullion received, for November:

Gold.	Fine ounces.	Value.
English coin	296,912.416	$6,137,724.41
Chinese bars	2,517.923	52,050.10
Australian bars	101,446.077	2,097,076.51
Other sources	209,299.861	4,326,612.12
Total	610,176.277	$12,613,463.14
Silver	58,935.27	$29,797.25

Coinage consisted of $152,000 in half-dollars, $76,000 in quarter-dollars, and ₱4000 in Philippine one-centavos. Coin, bullion, etc., on hand at the end of the month totaled $360,219,025.78. A feature of 1915 was the large quantity of foreign coin and bullion received.

Cyanide Consumption on the Rand

*IN the treatment of 25,701,954 tons of ore in 1914, there was purchased for consumption a total of 10,518,009 lb. of cyanide and 8,543,014 lb. zinc. This gives an average of 0.4 and 0.32 lb., respectively, per ton. The present annual requirement of sodium cyanide is 5000 tons, costing at current prices about $2,400,000. The possibilities of economizing in the consumption of cyanide was first investigated by the Buyers Committee of the Chamber of Mines and the consulting metallurgists of the Rand. The latter agreed that no application of known methods could be relied on to reduce the consumption materially in an economic manner. Special trials made a year ago showed a loss of gold more than balancing any saving in cyanide. Later, experiments were made under the control of a sub-committee consisting of W. A. Caldecott, K. L. Graham, E. H. Johnson, and H. A. White. These were mostly done in the laboratory of the Consolidated Gold Fields of South Africa by C. A. Meiklejohn, and were presented at the Society's meeting by H. A. White.

A theoretical limit to the minimum consumption of cyanide is set by the fact that the ore, crushed in water, carries into the collected charges a large amount of moisture; this water must be brought up to the cyanide strength required for extraction. For example: assume 50% sand at 15% moisture with a strength of 0.05% KCN, and 50% slime at 40% moisture with 0.01% KCN; this would give a loss of 0.12 lb. KCN per ton of crushed ore, and the exact figure will depend on the proportion between sand and slime and the moisture with each.

Another way of looking at this is to note that as the solution in stock is always kept at a certain average strength, the water brought into the plant as moisture must be brought up to that strength by the addition of cyanide, one way or another, and this cyanide must go to the residue or be dissipated elsewhere. This dilution effect is, of course, minimized by crushing in solution.

If to this is added the cyanide converted by contact to KCNS, $K_4Fe(CN)_6$, etc., a limit is reached which cannot be improved upon in practice, and to it must be added the self-decomposition of the solution while standing in sumps.

The cyanide going to the residue-dumps in various forms must represent the dilution loss, less the decomposition and HCN or other gas losses. Any saving in these two directions must therefore be partly discounted by increase in cyanide sent to dumps.

No attention need be paid to cyanide used in dissolving copper, silver, gold, mercury, or zinc, which merely has the effect of a temporary accumulator.

The theoretical minimum cyanide consumption for Geduld ore, based on 60% of the pulp (that is, 40 tons of water with 60 tons of dry slime) and 40% of sand of 15% moisture (that is 15 tons of water to 85 tons of dry sand) after allowing for cyanide required to raise the associated water to 0.3 lb. NaCN per ton for slime, and to 1 lb. per ton for sand, amounts to 0.19 lb. per ton of ore treated. To this must be added 0.07 lb. converted into unavailable products. The irreducible minimum of 0.26 lb. NaCN per ton is thus arrived at, and this shows a possible saving in this case of only 0.06 lb. per ton if there were no losses in the form of gas.

Of course, a saving could be effected if lower cyanide strengths were possible without corresponding losses of gold in the residue, but that is not generally the case, and the point must be emphasized that any saving of cyanide by means of increased alkalinity or in any other way of reducing gas losses must be partly offset by increased amount of loss in residue moisture.

It is, however, a theoretical possibility that the CO_2 of the boiler flue-gases might be utilized to displace the HCN in the sand and slime residues, and in the former case the use of cyanide destroyers previous to sand-filling would thus be avoided and the HCN collected in alkali instead.

A number of experiments were undertaken, and are given in great detail. Briefly, they were as follows:

(1) Estimation, as NaCN, of the amount of total cyanide, ferro-cyanide, and sulpho-cyanide in sand-residue as discharged at the Simmer Deep.

(2) Estimation, as NaCN, of the amount of total cyanide, ferro-cyanide, and sulpho-cyanide remaining with settled charge of slime after treatment, and before same is discharged.

(3) Estimation same as No. 1 on sand-residue as discharged at the Rose Deep.

(4) Estimation, as NaCN, of the amount of total cyanide, ferro-cyanide, and sulpho-cyanide remaining with the settled charge of slime after treatment, and before same is discharged.

(5) Estimation, as NaCN, of total nitrogen in a sample of zinc-box precipitate from the Simmer Deep.

(6) Estimation of cyanide solutions from the Simmer Deep and Rose Deep for total nitrogen present.

These tests showed a total loss as NaCN of 0.305 lb. at the Simmer Deep, and 0.268 lb. at the Rose Deep. The loss due to the escape of HCN as gas into the air was 44.7 and 49.5% respectively. It was noticed that an increased proportion of the pulp treated as slime results in increased cyanide consumption, owing to the greater amount of cyanide-bearing moisture in slime-residue; and that the smaller loss per ton of slime at the Rose Deep is due to the lower cyanide strength required for treatment at that plant.

In a test to determine the effect of exposure of sump cyanide solutions to the atmosphere, it was found that

*Abstract from the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa.

loose or incomplete covering is practically useless in preventing loss of alkali or cyanide; with weak solutions there is no loss of HCN as total cyanide, and but little loss as free cyanide occurs while available protective alkali is present; with strongest solutions the loss of HCN, both as free cyanide and total cyanide, becomes serious when available protective alkali is below 0.01% NaHO; and, comparing previous results, it is evident that the presence of zinc enormously decreases the loss of HCN by hydrolysis.

Another investigation covered the exposure to the atmosphere under varying conditions of working cyanide solutions. The conclusions to be drawn from a careful consideration of the exposure experiments, which are sufficiently comprehensive and consistent when account is taken of the various sources and conditions, may be briefly stated as follows: The loss is incomparably greater in pure synthetic solutions, even with added alkali, than is the case with ordinary working solutions; and a very heavy loss is shown in the presence of little or no protective alkali, when determined with addition of ferro-cyanide. This suggests that it is safer to omit the addition of ferro-cyanide in mill-tests.

An estimation was made of the amount of cyanide consumed during the treatment of a charge of collected slime, from the time of leaving the collectors till immediately after transfer to the first settling-vat. This resulted in 0.0158 lb. KCN, or 0.0122 lb. NaCN, per ton of slime treated. In transferring from the first settlement to the second, the loss was 0.0188 lb. NaCN. A considerable loss takes place during the settlement and decantation in the vats. In each of these the solution loses 0.001% KCN during the time the charge is under treatment. The loss during the treatment is considerable, and if this is taken as representing the loss by evaporation of HCN during the slime treatment, it will account for more than 0.14 lb. NaCN per ton of slime treated.

At the Rose Deep the consumption of NaCN is 0.0442 lb. per ton during transfer of slime from the collector to a Trent agitator, during agitation in this machine, and during transfer from it to the first settling-vat. No decomposition of the KCN in solution could be observed at the end of 72 hours from the action of the mill-service water.

Tests were made on regeneration. In ore, the cyanide regenerated equalled 28.9% of the total cyanide lost during agitation. This was in a closed vat. This was confirmed by using absorption-towers.

At the same meeting of the Society (September 18) a paper on the prevention of hydrolysis in cyanide solutions was presented by H. M. Leslie. He said that in ordinary practice it has always been recognized that a great deal more cyanide is used for dissolving the precious metals than is theoretically necessary, and various reasons have been put forward to account, in individual cases, for high consumptions; but in stating that, no one has ever yet put forward a reason to account for this large excess of cyanide which is necessary in present practice, and which excess also applies to cyanide practice in general. A cyanide solution undergoes gradual decomposition; it evolves hydrocyanic acid, and this decomposition is not prevented by the use of excess alkali; the evolution of hydrocyanic acid means loss or consumption of cyanide in working practice, and it is this loss which is accountable for the large excess of cyanide which has to be used over and above that which is necessary for efficient extraction.

Experiments demonstrated clearly the following points:

That simple cyanide solutions decompose by the hydrolysis of the solution; that the percentage loss by this reaction is greater in a given time, the weaker the solution; that increased temperature accelerates this decomposition; that the alkali formed as a product of the hydrolytic action has little or no protective action on the remaining cyanide, so that hydrolysis goes on until all the cyanide is destroyed; and that the protection afforded by the addition of an excess of caustic alkali is by no means complete, and that the protection is only of a very temporary nature.

An investigation into the protection afforded to a simple cyanide solution, by means of a cover, showed the loss in a covered vesssel is small compared with that in an open one. This loss was found due in accordance with the equation

$$KCN + HOH = KOH + HCN$$

Larger tests, on a working-scale, at the Village Deep mine, were made, to see if a loss was really being made which the 'closed' system would prevent, and if it was sufficient to justify any modification of plant. A large loss of cyanide, due to evaporation, was found; in the decantation-plant definite results were obtained, showing a loss of 0.0013% KCN per 24 hours, amounting to 32,572 lb. of 100% KCN per year, added to which is 10,857 lb. per year lost from the clarifiers on this solution, a total of 43,429 lb. Other tests were made, and it was ascertained that there was a difference of 0.2092 lb. per ton of 100% KCN, or 0.161 lb. of 130% KCN, in favor of the closed system per ton of sand treated. This was done at a small test-plant. The cyanide consumption at the Village Deep plant is 0.3 lb. 130% KCN per ton, or 0.39 lb. of 100% KCN. This might be reduced to 0.139 and 0.1806 lb. respectively by using the closed system of treatment. Pachuca tanks would also show a reduction by being closed.

Calculating the present rate of treatment on the Rand as 27,000,000 tons per annum, and the cyanide consumption as 0.3 lb. of 130% KCN, a saving by closed method would mean 1250 tons per year, say $770,000. [It is significant that Mr. Leslie did not estimate the cost of covering treatment vats, etc., without doubt a large expense.—Editor.]

The last tabulated report of the Transvaal Chamber of Mines shows that 10,048 stamps and 328 tube-mills, working 26.46 days, crushed 2,470,760 tons of ore, equal to a stamp-duty of 9.49 tons. The yield was $6.19 per ton, and costs $4.20. The working profit was $5,050,000.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

A CUBIC INCH of gold contains about 10 troy ounces and is worth $200.

BORNITE contains from 77 to 55% copper, and 18 to 6% iron, with the formula Cu_5FeS_4.

HEAT-LOSSES in electric furnaces occur around the charging-doors, tap-holes, and where the electrodes pass into the furnace. The latter loss cannot be reduced with the present design, but the others can be.

THE USE OF THE SLIDE-RULE by engineers and men about mines should be encouraged. Being able to settle quickly a question, involving numerical calculations, when it is being discussed is a matter of constant advantage, and a slide-rule in a handy leather-case for the pocket is an invaluable adjunct to a man who must consider costs.

IN BUSINESS there are two stages: one when the business is small, and can and should be dominated by an individual; and the other when the business has grown to such a size that it requires an organization. The dividing line is clear, but difficulty arises when one phase passes to the other. This applies to mining as well as other industries.

BELTED ALTERNATORS can be used to advantage in many installations where the space occupied is not a deciding factor in the selection of the generating-unit. Their lower first cost, as compared with direct-connected units, and the ease with which these generators may be connected to an existing source of power, as an engine, water-wheel, or line-shaft used for driving other machinery, has led to an extensive use of this type of alternator.

CANARIES have been used in coal mines to show a deficiency of oxygen in the air, but recent tests by the U. S. Bureau of Mines at Pittsburg proved that the use of these birds is not altogether reliable. Guinea-pigs have been used in Western Australian gold mines to note the effect of rock-dust, and subsequent examination of their lungs; but these animals evidently knew something was wrong, and buried their snouts in their fur, thus defeating the investigation.

CHANGE-HOUSES are necessary to the comfort, contentment, and efficiency of miners, millmen, and smeltermen. Every company that can afford it should erect one, and it is gratifying to note that the advantages of having a bath, dry, or change-house is becoming largely understood. In dirty mines and poisonous works men finish work in a considerable mess, making in many cases changing absolutely necessary. Seven States require change-houses by law, while in 13 States, where this is no law, many companies have supplied them. Good material and sanitary ideas should be used in construction, and they should be well lighted and heated, with arrangements for drying wet clothes. Forty gallons of water per man-day is a reasonable consumption.

THE ELECTRIC-FURNACE is considered to be able to produce steel of superior quality to that made by other methods. The furnace makes a temperature higher than any other furnace, and produces such temperature economically; it produces this without contamination of the charge through gases and other impurities, and in case of the induction-furnace, without contamination through carbon; and it offers the possibility of controlling the temperature within limits which are entirely beyond the reach of the older types.

STARTING a load suddenly or when there is excessive slack is one of the most destructive influences on wire rope under any conditions of work, and especially a drilling-cable. Experiments made by placing a dynamometer between the rope and the load prove this contention, as when there was 2½ in. of slack, the stress on the rope was 39% greater than when the rope was pulled slowly; with 3 in., 65%; with 6 in., 122% or more than double; and with 12 in. stress was three times as great. When a new wire drilling-line is put on, it should be run a few times without doing any work, in order to get its 'set.' The cause of a lot of wire-rope trouble is due to kinks, and care should be taken to prevent them. All small bends and kinks should be taken out by placing the line on a wooden block and hammering it carefully with a wooden or copper mallet. If such kinks are not taken out promptly, there is likely to be a projection where the kink appeared, and when the wires at this point rub on the side of the casing, there is excessive wear.

ANTIMONY-GOLD ORES are troublesome to treat by cyanidation; this is the experience in New South Wales, Western Australia, and Rhodesia. At Hillgrove, in the first-named country, the caustic soda process was used for a time. In the Murchison range of Rhodesia the occurrence of antimony has hindered work, but a plant has been started at the United Jack mine, in which the McArthur-Forest process is used. The ore is reduced to 30 mesh in two No. 7 ball-mills. From bins it is conveyed to tanks 23 ft. 9 in. diameter, and 8 ft. deep. A solution of caustic soda is pumped on ore, which assays $7 gold and 12.5% antimony, and allowed to percolate through it. The resultant solution carrying the antimony sulphide chemically combined, is drained off to three carbonators, where it is treated with carbonic acid gases from a lime-kiln. The antimony is precipitated as an amorphous sulphide, and the sludge is pumped to a filter-press, the cakes being finally dried and sent to the market. The solution from the filter-press is used again. The sand residue is treated in the usual way by cyanide solution, which goes through zinc-precipitation-boxes for the recovery of the gold.

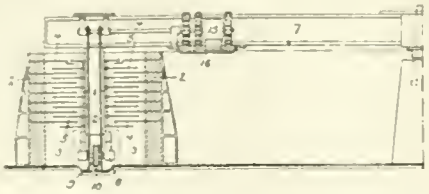
Recent Patents

1,157,176.—Separation of Metallic Sulfids from Ores. Thomas Mackellar Owen, Sydney, New South Wales, Australia, assignor to Edward William Culver, Sydney, New South Wales, Australia. Filed February 27, 1914.

1. In selective or preferential froth flotation separation of metallic sulfids from slimes, the herein described process for augmenting the flotative quality of certain sulfids in relation to certain other sulfids, which consists in adding to and agitating with the pulp a limited proportion of alkaline permanganate.

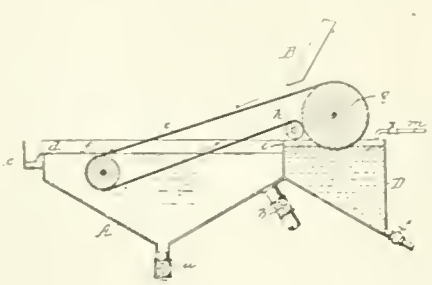
2. The herein described improved process of preferential or selective froth flotation of lead and zinc sulfids, which consists in subjecting slimes to contact with alkaline permanganate in solution, agitating the slimes in water containing a flotation medium, removing the leady float concentrate, adding acid, reagitating and removing the zincy float concentrate.

1,159,141.—Furnace and Allied Structure. Utley Wedge, Ardmore, Pennsylvania. Filed March 4, 1914.



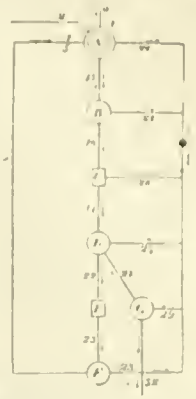
1. The combination, in a furnace, of inner and outer fixed annular structures, the inner having annular hearths projecting outwardly therefrom and the outer having annular hearths projecting inwardly therefrom, and an intermediate rotating annular structure supported from below and having annular hearths projecting in both directions therefrom, the inwardly projecting hearths lapping those of the inner fixed structure and the outward projecting hearths lapping those of the outer fixed structure.

1,159,713.—Separation of Minerals by Flotation. Lewis G. Rowland, Brookland, N. Y., assignor to New Jersey Zinc Company, New York, N. Y., a corporation of New Jersey. Filed August 1, 1914.



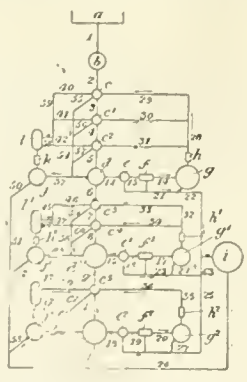
1. The method of separating sulfid constituents from ores in which they are contained, which comprises feeding the solid particles of the ore in a finely divided condition upon a moving layer of an oleaginous liquid having a selective action for the sulfids of a character to effect flotation, progressively feeding said layer with its charge of ore into a flotation liquid at the surface thereof, and floating off and recovering the floating sulfids; substantially as described.

1,158,511.—Extraction of Metals from Their Ores. Hugh M. Leslie, Glasgow, Scotland. Filed December 30, 1911.



1. The improvement in the cyanid process for treating ores consisting in collecting the gases liberated at all stages of the process and conducting them continuously to a regenerating vessel wherein they are subjected to the action of an alkali so as to convert any hydrocyanic acid gas into a simple cyanid solution which latter is drawn off and added to the solution, from which the metal has been extracted, in the sump and thereafter supplied to the vessel in which the ore pulp is undergoing treatment, the arrangement constituting a closed circulatory solution system whereby the hydrocyanic acid gas which is constantly evolving from all the tanks, vessels or places in which cyanid liquor is used or stored and which go to form the various units of a cyanid plant is continuously being re-used in the process.

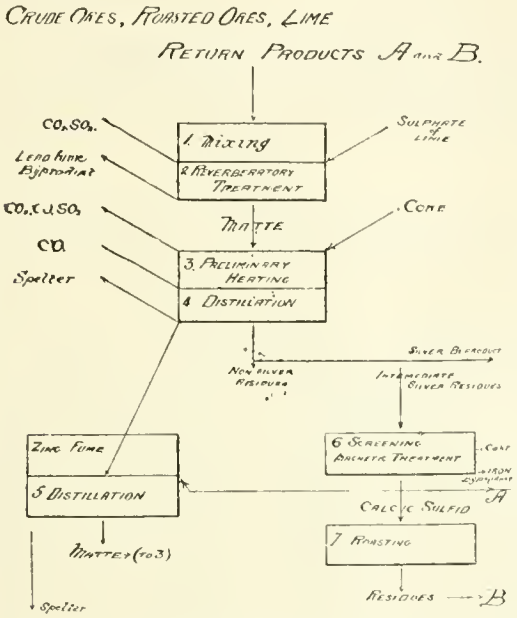
1,158,513.—Treatment of Ores by the Cyanid Process. Hugh M. Leslie, Glasgow, Scotland. Filed December 30, 1911.



1. The closed circulatory cyanid process for the treatment of ores for the extraction of metals, consisting in effecting the treatment in stages, the first stage consisting in continuously bringing the ore pulp into contact with cyanide solution, then agitating the same, then conveying the same to the second stage which consists in removing surplus solution and then transferring the residue, from which surplus solution has been removed, to the third stage which consists in treating the same with a weaker cyanid solution, then agitating same and then conveying same to the fourth stage which is a repetition of the

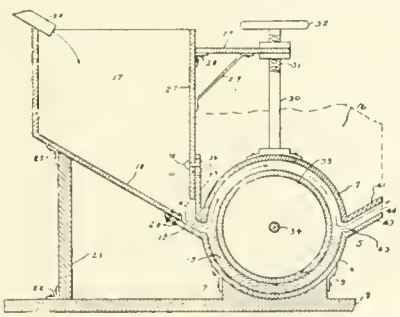
second stage, the process further consisting in collecting the liquid removed at the second and fourth (dewatering) stages, extracting the metal therefrom and re-using same as required throughout the process, and also in collecting the whole of the cyanogen containing gases evolved during all stages of the process and re-using same in conjunction with air to agitate the ore pulp and convey same from stage to stage.

1,157,375.—Process for the Manufacture of Spelter from Ferruginous and Admixed Zinc-Blende Ores. John James Fingland, Kaslo, British Columbia, Canada. Filed September 10, 1913.



1. The herein described steps in the process of manufacturing spelter from ferruginous and admixed lead and zinc-blende ores, which consists in heating a mixture of crude ore, roasted ore, and lime, thereby forming litharge and maintaining the heat treatment until the litharge has been driven off by volatilization.

1,157,836.—Amalgamator. Erastus B. Bennett, Denver, Colorado. Filed November 23, 1914.



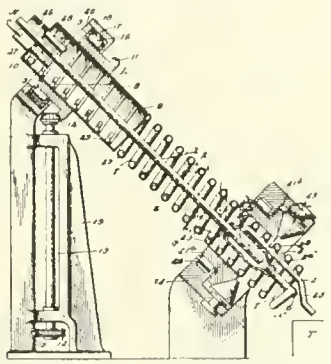
1. An amalgamator, consisting of two semi-circular members, arranged in conjunction with each other to form a circular chamber, said members being normally separated to form longitudinal openings the entire length of said chamber on opposite sides of the latter for the intake and discharge of the ore to be treated, an amalgamating roll journaled in said chamber, and one of said semi-circular members being adjustable to vary the size of said intake and discharge openings, a space being provided between said amalgamating roll and one of said semi-circular members for the passage of the ore through said chamber.

1,162,044.—Process for Extracting Valuable Copper Constituents from Cupriferous Ores and Their Gangues. Eugene Erdös, Kolozsvár, Austria-Hungary, assignor to Azurit Company Limited for Chemical Industry Kolozsvar, Kolozsvár, Austria-Hungary. Filed February 26, 1914.

1. Process for extracting valuable copper constituents from materials containing the same consisting in disintegrating the said materials and thereafter leaching the same with aluminium sulfate solution.

2. Process for extracting valuable copper constituents from materials containing the same consisting in disintegrating the said materials, roasting the said materials and thereafter leaching the same with aluminium sulfate solution.

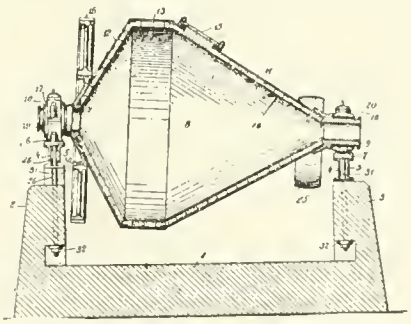
1,160,849.—Precipitation. Harry R. Conklin, Joplin, Mo. Filed April 7, 1915.



1. The method of precipitating substances from solutions which comprises passing a solution of the substance successively over pieces of a suitable solid precipitant moving in succession.

2. The method of precipitating substances from solutions which comprises subjecting a solution of the substance to pieces of appreciable volume of a suitable solid precipitant moving in succession in a direction opposite to said solution.

1,161,859.—Apparatus for Disintegrating Ore and Other Material. Harry W. Hardinge, New York, N. Y., assignor to Hardinge Conical Mill Company, New York, N. Y., a corporation of New York. Filed December 31, 1908.



1. In an apparatus for disintegrating ore and other material, in combination, a barrel or drum having axial inlet and outlet trunnions, bearing members for the trunnions, each having a cylindrical inner surface surrounding a trunnion, and a spherical outer surface, supporting members having spherical inner surfaces to fit the said bearing members, a foundation upon which the supporting members are mounted, means for raising and lowering a supporting member to vary the inclination of the axis of the barrel, and driving means for rotating the barrel, including a driving shaft parallel with the axis of the barrel and supported by said supporting members whereby to remain substantially constant in position relative to the barrel at all positions of the latter.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ATOLIA, CALIFORNIA

LATEST FROM THE TUNGSTEN AREA, INCLUDING PRICES FOR ORE

A legal township organization, followed by the laying out and platting of a townsite to be known as Atolia, is almost accomplished. The tract covers 10 acres, on mining ground, the mineral rights of which are reserved to the original locators. Lots are being sold every day. A new general store has been built, to be open for business on January 1, a bakery will be built by a San Diego man, a pool-room, a stationery and cigar-store, with a club-room annex, are other substantial evidences of progress in this important tungsten district.

Brock & Lipp, lessees at the Osdick group, received a check for $55,000 for tungsten ore shipped to New York in November. Another lot was bought from the same lessees by Atkins, Kroll & Co. of the Atolia company. The price paid was said to be $48 per unit of 60% WO_3.

The Scheelite group of 10 claims, which adjoin the Atolia company's ground on the east, is being prospected by means of a Keystone drill.

The recently erected mill is now working at full capacity, night and day, on ore extracted from the Atolia company's ground. When ore is short, there is 500,000 tons, more or less, of tailing that is being re-treated with good results.

The area of the tungsten belt is gradually increasing. Scheelite float is now being found on the Kramer road, three miles south of Atolia. Bailey and Anderson found a chunk of scheelite weighing over 300 lb., yielding nearly 200 lb. of high grade, which brought $1.50 per pound.

There are half a dozen, or more, buyers of high-grade tungsten ore at Randsburg and in this district. Some of these are paying over $2 per pound for grades better than 60%. As a consequence, there is more or less high-grading, and purloining of ore from dumps, warehouses, and cars, when shipments are being made. Last week two sacks worth over $400 disappeared quickly when the watchman was not looking. A peculiar arrest was made. It is difficult to find out from where the ore comes, as many who sell scheelite buy for cash, in small quantities, from others and then re-sell it to agents or middlemen, who market the valuable high grades to eastern steel manufacturers. Tungsten is now so high that smaller shipments than carload lots must be sent by express. Several tons were thus shipped in a regular express-car last week. The rate is $190 per ton by express for high-grade ore in sacks.

Victor Lipp has purchased the McGinnis hotel of Randsburg for $3000. During the scarcity of accommodations at Atolia, the hotel is being used as an adjunct to his tungsten mine, where he can board and lodge his employees. The acuteness of this problem of accommodations is illustrated by the fact that there are nine regular boarding-houses, and two restaurants and chop-houses, that are 'rushed to death.' The overflow goes to Randsburg, five miles away, by jitney.

More than 100 men are working at No. 1 shaft of the old Churchill mine, on the various levels. The main shaft is down about 100 ft., with the bottom in ore of good grade. Driving and stoping is under way for several hundred feet east and west, showing continuity of the main vein. At present the principal producing mines are the Churchill, No. 1, 2, and 3; Papoose, Piute, Para, Paradox, and Spaniard lease. Harry Hughes and R. D. Mayhood are the principal operators of leased ground from the Atolia Mining Company.

All leases of ground owned by the Atolia company will terminate on the first of January 1916. Leases of the Osdick, Scheelite, Toboggan, and other groups, however, will continue indefinitely. These groups are all outside of the 90 or more claims held by the Atolia company, only a half dozen of which are being worked as quartz producers. Several others, located and patented as lode claims are being worked by Italian squads for 'float' digging. The float diggers receive $3 per day wages.

WASHINGTON, D. C.

MEETING OF THE PAN-AMERICAN SCIENTIFIC CONGRESS.—TITLES OF SOME OF THE PAPERS.

During the last two weeks there has not been much mining legislation at the Capital, but the second Pan-American Scientific Congress has been of interest to mining men. It was in session from December 27 to January 8, during which time there were a large number of meetings at which many papers on a variety of subjects were read and discussed by prominent men. The Congress was divided into many sections and sub-sections, the papers being grouped according to their relationship to subjects. Mining, metallurgy, economic geology, and applied chemistry made up section 7, with Hennen Jennings as chairman. Van H. Manning, director of the U. S. Bureau of Mines, was chairman of the sub-section devoted to mining; W. R. Ingalls, president of the Mining and Metallurgical Society, chairman of the sub-section on metallurgy; George Otis Smith, director of the U. S. Geological Survey, chairman of the sub-section on economic geology; and Charles E. Munson, former president of the American Chemical Society, chairman of the section on applied chemistry. In the 19 sub-section meetings, all of which were fairly well attended, considering the diversions, over 50 papers were read and discussed.

Some of the papers were as follows: 'The Relation of Mining to the Pan-American Countries With Special Reference to the Mineral Resources of Peru,' by Hon. F. A. Pezet, Peruvian minister to the United States; 'The Value of Technical Societies to Mining Engineers,' by Dr. R. W. Raymond, past secretary A. I. M. E.; 'The Influence of Technical Journals Upon Engineering Education,' by T. A. Rickard, editor of the MINING AND SCIENTIFIC PRESS, San Francisco; 'The Possibility of Treating by the Cyanide Process the Complex Silver or Silver-Gold Ores of the Latin American Republics,' by G. H. Clevenger; 'Cyaniding in South America,' by H. A. Megraw; 'Mining in Ecuador,' by J. W. Mercer; 'The Electric Furnace in Metallurgy,' by J. W. Richards, Lehigh University; 'The Iron Mines of Cuba and the Methods of Preparing Their Ore,' by J. E. Little, Felton, Cuba; 'Metallurgy of Native Silver Ores in Southwestern Chihuahua,' by Walter M. Brodie; 'Concentration by Flotation,' by F. G. Fuchs, Lima, Peru; 'The Copper Mining Industry in the Americas,' by Walter H. Weed; 'Improved Mining and Metallurgical Methods as an Aid to Conservation,' by L. D. Ricketts; 'Buying and Selling of South American Non-ferrous Metals,' by L. Vogelstein; 'History and Development of Gold Dredging in Montana,' by Hennen Jennings; 'Recent Progress in Electrical Smoke Precipitation,' by F. G. Cottrell; 'Metallurgy at Braden,' by B. T. Colley and R. E. Douglas; 'Metallurgical Operations in Chuquicamata,' by

E. A. Rose; 'Ore Dressing,' by R. H. Richards; 'Mining Laws of Panama,' by J. F. Sanchez; 'Mining Law,' by J. W. Thompson; 'The Prospect of Marketing South American Zinc Ores,' by W. R. Ingalls; 'Lead and Zinc in the United States,' by C. B. Siebenthal; 'Iron Ore Deposits of the Americas,' by C. K. Leith; 'Value of Mining Property,' by J. R. Finlay; 'Mining the Pioneer of Intimate Commercial Relations,' by F. F. Sharpless, secretary of the Mining and Metallurgical Society; 'Development Work and Placer Operations of the Chile Exploration Co.,' by Pope Yeatman; 'Placer Mining Methods and Operating Costs,' by Charles Janin; 'Metallurgical Practices at the Tin Mines of Bolivia,' by Scovill E. Hollister, Bolivia; and 'Bolivian Tin,' by Howland Bancroft.

HOUGHTON, MICHIGAN

COPPER OUTPUT IN 1915.—FACTORS AFFECTING OPERATIONS.—COPPER RANGE, WINONA, OSCEOLA, CALUMET & HECLA, AHMEEK, ALLOUEZ, AND MOHAWK.

The production of copper from the Michigan mines during 1915 broke all records, with a total of 259,352,000 lb. The nearest approach to this figure was in 1909, when it was 231,870,000 lb., and 230,437,000 lb. in 1905. Individual yields were as follows:

Mine.	Pounds.	Mine.	Pounds.
Osceola	20,045,000	Copper Range Con., including Baltic, Champion, and Trimountain	54,000,000
Ahmeek	21,500,000	Winona	1,500,000
Wolverine	7,400,000	Hancock	1,400,000
Mohawk	15,800,000	Tamarack	3,700,000
Isle Royale	9,500,000	White Pine	3,000,000
Calumet & Hecla	72,000,000	La Salle	700,000
Centennial	2,500,000	Houghton	270,000
Allouez	10,000,000	South Lake	82,000
Mass	6,000,000	Lake Copper	855,000
Superior	4,000,000		
Franklin	2,600,000		
Victoria	2,500,000		
Quincy	20,000,000		
		Total	259,352,000

In considering these figures from a shareholder's point of view it should be understood that they are not the present annual rate of production, which is now 25% higher than the rate for the year. The first quarter of 1915 showed an output much below normal. When the War started in August 1914, the general condition of the copper business was not good. There were enormous quantities of metal on hand. It was a task for the treasuries of the companies to carry their unsold metal. All business was depressed. Copper mines in Michigan curtailed production; some went on half time, and some on three-quarter time. This was the condition when the year 1915 opened. In February the situation showed improvement, and by March all of the companies were turning their attention to an increased output. The War resulted in a big demand for copper. Lake Superior mines did not benefit much until April and May; it has been maintained ever since. Wages, dividends, and treasury surpluses were increased.

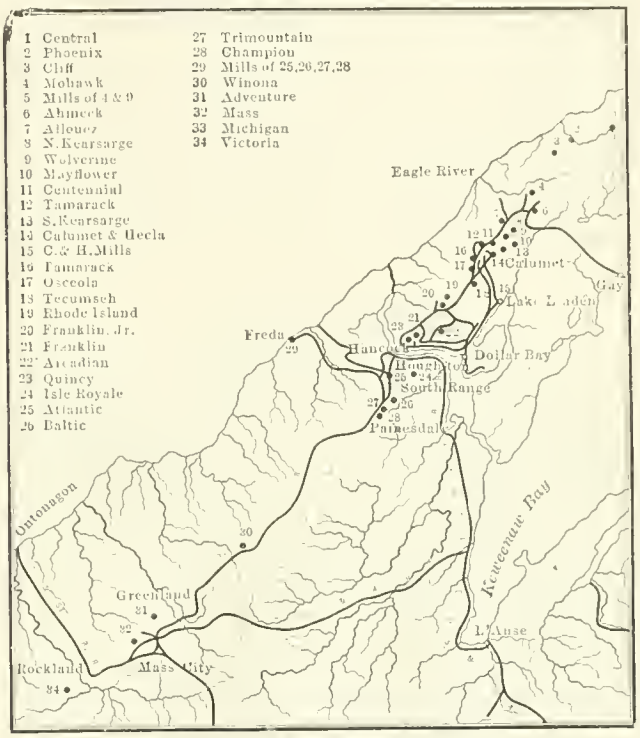
At present every mine's output of copper is only limited by its milling capacity. The output for 1915, while it was the largest on record, shows, in addition, a much greater increase in ore treated; also the largest working force ever employed here, a total of 18,000 men, and a yearly pay-roll of $17,000,000.

The most interesting feature of the present situation in this State is the fact that 1916 will show a general betterment of at least 20% over 1915, provided the demand and price of copper averages the same as in 1915.

Perhaps the most remarkable yields are those of the three mines of the Copper Range Consolidated Co., which owns the Baltic, Trimountain, and Champion, but only a half interest in the third named. The output of these three was 54,000,000 lb., which is 30% more than their combined output in any previous year. More than half is from the Champion, which did well both in the ore extracted and the increase in copper-content; as high as 50 lb. for a month at a time, a yield for an amygdaloidal mine that is rarely equalled.

The output of the Winona, 1,500,000 lb., includes 600,000 lb. which was taken out by contract and tribute mining, upon which the corporation received a royalty. The Winona was inactive part of the year.

The production of the Osceola Consolidated includes that of the North Kearsarge, South Kearsarge, and the original Osceola. The yield is larger than many anticipated, owing to the general belief that the life of the property is limited. The



THE COPPER COUNTRY, MICHIGAN.

showing is 2,000,000 lb. better than any made in recent years, with the exception of 1909, when it was 25,000,000 lb. The record is all the more creditable when it is remembered that at the Kearsarge there was interference with hoisting owing to accidents and the completion of some construction. In addition to its earnings of at least $24 per share, the company at present has the largest treasury balance of any in the district, excepting the Calumet & Hecla. The most encouraging feature is the fact that its underground openings in the North Kearsarge, where the ore has been extremely low grade, are slightly improving.

Calumet & Hecla's performance is the more remarkable when it is remembered that the increased tonnage of ore came entirely from the lower-grade amygdaloid shafts. Naturally the conglomerate has to be conserved. It is quite a different proposition handling Calumet & Hecla with a grade that averages 80 lb. per ton, and with about 20 lb. The output is better than it has been in six years, and with its subsidiaries the total was 146,000,000 lb., about 66% of the entire Lake Superior region. In the profit of this subsidiary production, however, the Calumet & Hecla treasury participates only to the limited extent of its ownership, one-half of Ahmeek, one-third of Osceola, and similar proportion in its other subsidiaries. Calumet & Hecla's present dividend rate is on a basis of $60 a year, yet the earnings for 1915 undoubtedly were better than $80 a share on its own mine alone.

The richest subsidiary of the Calumet & Hecla is the Ah-

tucks. The output in 1916 will probably show an increase of 30% over that of 1915. Two new stamps are to be erected at once. This work will take at least four months, possibly six. In the meantime the mill capacity is taxed to the utmost. The quality of ore maintains a good average, and the workings which now are well opened to provide for the additional tonnage needed show the average quality of the Kearsarge lode.

In 1903 the Ahmeek Land & Improvement Co. was organized, and purchased the surface rights of three estates in Keweenaw county. The mineral rights under the town of Ahmeek were recently sold to Thomas F. Cole of Duluth for $4000 an acre, or $160,000 in all. Evidently the idea is to develop the Kearsarge lode, but a 2500-ft. shaft will have to be sunk.

Allouez is another Calumet & Hecla subsidiary which is now, after five years of thorough preparedness, in shape to produce copper at the rate of at least 10,000,000 lb. annually for 10 years at least, and 25 years with reasonable certainty. Costs will be lower in 1916 than ever before, as practically all necessary construction is done, and underground openings are further in advance than in any mine in Michigan.

Mohawk's performance is the talk of the district. Earnings for 1915 are over $15 a share, and the present rate of earnings is better than $20. Further, the mine is in excellent condition.

TORONTO, ONTARIO

Cobalt and New Developments.—Porcupine Notes.—Kowkash.—Canadian Mining & Exploration Co.

Lately there has been a marked revival of interest in Cobalt, stimulated by the opening of new veins in some of the older properties. There is an active demand for prospects, and the share market has been buoyant, with a general upward tendency. While shipments have increased, they are not being rushed, as most of the companies are pursuing a conservative policy, thinking that the price of silver will advance.——The Nipissing has added considerably to its ore reserves. In a cross-cut from an old drift a vein which yielded nothing on the surface has been opened 27 ft., assaying 3000 oz. per ton over 1½ in. Driving 60 ft. above the No. 4 level on a vein paralleling vein 98 has opened a 3-in. shoot, containing 2500 oz. per ton.——The Conlagas has purchased the old Agaunico mine on Lake Timiskaming, one of the early producers of the district.——Work is to be resumed on the Ophir Cobalt, which was closed down some years ago for want of funds. B. Neilly will be in charge.——The old Silver Queen is being worked from the Right of Way shaft, and making regular shipments of high-grade ore.——The new vein recently found on the Cobalt Comet is opening well at depth, containing 4000 to 5000 oz. of silver per ton at 20 ft. The shaft sunk on it will be continued to connect with the old workings.

At Porcupine good progress is being made with the new central shaft of the Dome; it is expected to reach a depth of 700 ft. in March. The hoist will have a capacity of 75,000 tons per month, which will be considerably ahead of the requirements of the mine for some time to come.——The Tisdale Mining Co. is sinking a shaft near the Dome Lake boundary. ——Diamond-drilling on the Preston East Dome has shown a mineralized zone 200 ft. wide, traversing the property for 2000 ft. Surface development has been started to uncover promising looking veins cut during drilling.——The directors of the Dome Extension have been authorized by the shareholders to sell 1,000,000 shares at not less than 25c. each.

Though the original discovery on the King Dodds claims in the Kowkash district has proved disappointing, the vein which showed so rich on the surface having pinched out at the depth of a few feet, the latest report of Percy E. Hopkins, of the Ontario Bureau of Mines, on the district generally is understood to be of a favorable character, especially as regards the prospects to the west of the district along the line of the National Transcontinental railway. It has not been considered advisable to publish it, as too little development has been done to form a basis for a conclusive decision as to the value of the region.

The Canadian Mining & Exploration Co. organized in 1912 by New York and Canadian people, with a capital of $5,000,000, to investigate and exploit mining property, is being wound up, and the money returned to investors. It investigated about 1500 mining propositions, but found none that were considered worth purchasing at the price asked. In the meantime the capital was invested in good securities, and the shareholders will, it is stated, be repaid in full.

The annual report of the Conlagas Mines, Ltd., of Cobalt, has been issued. Development was confined to following small veins and extending certain cross-cuts. This work added 212,700 oz. to the reserves, which were estimated as 12,891,380 oz. on October 31. The mill treated 55,437 tons of ore. Shipments included 473.9 tons of concentrate assaying 2174 oz. per ton, and 133.2 tons of 233.3-oz. slime. The heads averaged 23 oz. per ton, and residue 3.94 oz. Ore shipped weighed 267.2 tons, containing 3519.6 oz. per ton. Silver sold totaled 2,002,053 oz. Mining and treatment cost 13.618c. per oz., exclusive of freight, smelting, and marketing, which was 3.252c. per oz. Dividends totaled $740,000, making $7,840,000 to date. F. D. Reid is superintendent.

During shaft-sinking at the Croesus gold mine in Munro township, $125,000 was extracted in 75 ft. of work. The vein has been cut at 200 ft., where it is high grade.

On January 20 the La Rose company will pay 1%, equal to $74,931, making $5,472,052 to date.

RAND, NEVADA

Notes on a District with Three Rich Mines.

Rand is in Mineral county, about 15 miles east of Walker lake. It has been somewhat sensational by having shipped upward of $100,000 of high-grade ore, also having opened large veins of excellent mill ore. Only three mines have been developed, but are shippers of rich ore.

The most important deal made in the camp so far is the sale of the Golden Pen mine to a syndicate of Western operators headed by Jesse Knight of Utah, associated with Adams and O'Neil of Los Angeles, J. H. Miller of Hawthorne, and others. The deal was closed on December 15, and the new owners immediately started 12 men working. High-grade ore is being hauled to Nolan spur, a station on the Southern Pacific railway. The price reported is $150,000, to be paid within one year. The Golden Pen has made very rich shipments; one car, the lowest grade shipped, averaged $118; another, $600; while a recent carload averaged $1018 per ton; smaller lots have contained as much as $18 per pound. One very unusual condition of the sale is the fact that the owners retain for their own use and operation, one high-grade shoot in the mine 20 ft. long, from which they are stoping some wonderful ore and will soon make shipment.

The Queen Regent Merger Mines Co. recently bought the Lone Star claims for $50,000. It has steadily developed the property with a good number of men and reports the opening of a 30-ft. vein on the first level, which in the second level is 40 ft. wide, with the hanging wall not yet reached. Development is now going on on No. 3 level. A good grade of mill ore has been opened, but rich material has not yet been cut as in the other mines, except at No. 2 shaft, where a block of ground was leased last November to Miller and Meaker, who have opened high-grade ore, and are now making shipments. In addition to this the lessees have opened a 5 to 7-ft. vein of fine mill ore.

Adjoining the Queen Regent on the west the Last Hope mine recently shipped a carload to the Hazen sampler, averaging over $80 per ton. It is thought that the Last Hope will, with cross-cutting at depth, open the huge vein of mill ore that is under development in the Queen Regent.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

November returns of the mines on Douglas island were as follows:

Results of operations.	Alaska Mexican.	Alaska Treadwell.	Alaska Juneau.
Stamps working	120	540	300
Ore crushed, tons	16,800	80,609	48,594
Gold from all sources	$27,959	$166,628	$82,003
Yield per ton	$1.66	$2.06	$1.72
Operating profit	$5,667	$67,472	$22,495
Construction charges	$9,618	$12,953	$24,352

In addition to the Treadwell operating profit, there was received from the Mexican and United companies, a total of $24,705, the amount of adjustment of construction expenses.

KETCHIKAN

(Special Correspondence.)—After a delay of two months, lessees at the Cymru mine at North arm have finally secured transportation for a small shipment of copper ore. The *Despatch* will load this ore, also about 300 tons from the Mt. Andrew mine, for the Tacoma smelter.

The Rush and Brown is now shipping to the Granby smelter at Anyox, British Columbia, and the first shipment to the plant from this mine, consisting of 700 tons, has just been delivered.

Recent developments at the old Hydah mine, Corta bay, has proved that the ore is practically continuous from the old workings to a distance of 350 ft. in an easterly direction, while several open-cuts have exposed magnetite chalcopyrite ore along the contact-zone, and at one place an open-cut exposes a solid sulphide body 15 ft. wide, averaging 3.5% copper. This deposit was traced from a magneto-metric survey made by W. L. Polson.

Gold mining in the vicinity of Twelve-mile arm and Hollis is proceeding with good results. The Julian mine at Harrais creek has been developed to a depth of 300 ft. on the vein, and J. H. Rodgers, the principal owner, has finally decided to enlarge the mining and milling plant, and make other improvements. Lessees on the old Puyalop mine are said to be making good.

Flotation experiments made on ore taken from the Apex group at McLeans arm are said to give satisfactory results. Mining in this district will become more interesting when it becomes more generally known that there are a number of low-grade copper-gold deposits containing large quantities of ore amenable to flotation.

A body of ore said to be 80 ft. wide, near Smeaton bay, averaging $1.80 gold per ton is said to have been bonded to J. T. Jones, representing Tacoma and Portland people.

Ketchikan, December 15, 1915.

ARIZONA

COCHISE COUNTY

The approximate copper production of the Calumet & Arizona and Copper Queen smelters at Douglas in 1915 was 75,000,000 lb. and 125,000,000 lb., respectively, both good increases. The totals include custom ores. Both companies have extended the sliding-scale of wage up to 25-cent copper, effective December 1, 1915. The price of metal on which wages are to be based will be the average quotation of electrolytic copper for the preceding calendar month.

GILA COUNTY

Two more units of the Inspiration mill are working, making 11 out of 18, treating 8000 tons per day. Improved driving gear has been fitted to the apron feeders supplying the gyratory crushers. A battery of motor-driven blowers for the flotation-plant is expected soon.

The raise above No. 12 level in the Arizona Commercial is nearly up to No. 11 in 8% ore. The output is now 500,000 lb. of copper a month.

Five cars of ore from the Iron Cap early in December assayed from 15 to 20% copper, netting $15,042. The profit for 1915 was about $130,000.

GREENLEE COUNTY

On December 27 the United States marshal, J. Dillon, and 50 deputies escorted 236 miners at Morenci from the Duncan refugee camp. The men are to do assessment work on the Detroit Copper Co.'s unpatented claims, and will be unmolested by the strikers on account of an injunction from the Federal court.

The strike is costing the Shannon company over $10,000 a month, not including loss of copper production.

On January 1 the strikers voted against accepting an offer from the Arizona, Detroit, and Shannon companies, which wished to resume operations with former employees, with an extension of the present scale of wages on a basis of 20c. copper, provided the men gave up their Western Federation of Mines charter. The offer meant an increase of 5% in wages for 5000 men, but no recognition of the union. A mediation committee of neutral people of Clifton acted in this offer. Nearly every American voted for acceptance, but the Italians and Mexicans were against it. It was further proposed by the companies to place the wage-scale on a basis in accordance with the selling-price of copper.

Under the proposed schedule the following scale would be in force: miners and muckers 39½c.; trimmers 31½c.; timbermen, 41½ to 51c.; furnace-men 39c.; skimmers 47½c.; boilermakers 62½c.; electricians 66½c.; carpenters 59½c., and machinists 62½c. per hour.

MOHAVE COUNTY

Much excitement prevails at Oatman through the 400-ft. level of the Big Jim cutting the hanging wall of what is thought to be the Tom Reed lode. So far it is 43 ft. wide, averaging $20 per ton.

Some good ore has been opened on the surface of the Times mine, about 4 miles from Oatman. A large sample is on view on Bush street, San Francisco.

YAVAPAI COUNTY

Three miles north of Constellation, R. T. Barton and son have opened silver-lead-vanadium ore to a depth of 60 ft. The vanadium is said to occur partly as beautiful crystals, and is of high value.

CALIFORNIA

The number of new oil wells drilled in California during 1915 was about 240 compared with over 400 drilled during the previous year. This decrease, in conjunction with the natural decline in productiveness of wells, accounts for the 10% short-

age in total production. Demand for oil has increased in the past few months, causing a reduction in storage.

On page 24 of the issue of January 1 it was stated that the State Mining Bureau chapter on Amador, Calaveras, and Tuolumne counties was by W. H. Fletcher; this should have been W. H. Tucker.

Butte County

A new type of dredge designed by L. D. Hopfield of the Natomas Consolidated, is to commence work at Oroville in a few days. Its purpose is to re-dredge the tailing-piles and leave the final material level. Mr. Hopfield considers that the owners of dredged land should pool their areas for the success of this scheme on a large scale.

It is reported that the Burlington property at Forbestown has been sold to Eastern people for $130,000. W. C. Ralston of San Francisco was instrumental in arranging the deal.

Eldorado County

(Special Correspondence.)—John D. Cover, of Seattle, has acquired, after personal examination, four gold quartz lode-mining claims in this county, situated on the Mother Lode between the Church-Union and the Laus Padre mines on the north fork of the Cosumnes river, about four miles south of El Dorado (formerly Mud Springs) railroad station. Three miles along the trend of the same formation south is the Montezuma quartz mine, which has been for the last nine months, and is yet, under extensive development in depth by George Wingfield of Goldfield and W. J. Loring of the Plymouth Consolidated, seven miles farther south. Mr. Cover intends to develop and equip his property in a modern manner.

Mining was started on the old Church-Union mine (two claims adjoining) in 1852, and the two properties have produced over $10,000,000 in gold. At the 200-ft. level there was a long shoot of ore 20 ft. wide, between good walls, that averaged $20 free gold per ton. The vein has been mined to a depth of about 2000 ft. It is said to be a good mine yet. The Church mine was named after 'Tom' Church of New York, who operated it for some years. The Rheta mine (the old Bay State) on which deep-level development on a large scale was recently started by B. C. Clark, is also on the same formation, about midway between the Montezuma and the Plymouth mines.

Placerville, December 26, 1915.

Steam-shovels will not be used as contemplated by the Webber Creek Co. at Cold Springs.

The Golden Center company of Grass Valley has acquired the Lady Emma and Noon Day quartz claims in the Nashville district. Some rich ore has been extracted from the Emma lately.

Inyo County

A transmission-line seven miles long is to be erected at once between Keeler and the Cerro Gordo zinc-lead mines. M. A. Stampher & Co. of Los Angeles has the contract.

Kern County

A large tungsten area is reported to have been discovered six miles south-west of Randsburg. It is in the tungsten belt, and can be traced from Atolia to White's and Powell's camp, and from the latter the ground is 2½ miles west. 'Float' ore contained as high as 75% tungsten. The field has been rushed.

Nevada County

The new change-house at the Champion mine on Dry creek is in full occupation. It is of corrugated iron, lined with asbestos, has a cement floor, hot and cold water installed, and accommodation for 350 men.

The North Star and Empire companies are to pay bonuses to miners. For the present the standard shift's work will be seven holes, depending on the character of the rock drilled. It is thought that some men will make up to $4 per day; the present wage is $3.

Shasta County

The monthly ore production of the Mountain Copper Co. at Keswick is about 15,000 tons. The smelter at Martinez is kept busy.

Ten stamps are working 20 hours a day at the Uncle Sam mine, four miles west of Kennett.

Sierra County

The Young America mine at Forest has been bonded to E. J. Wiley of Nevada City. The 1000-ft. adit is being prepared for resumption of work.

Stanislaus County

A new company, the Pacific Coast Manganese Co., with offices at the Monadnock building, San Francisco, is commencing work at Ingram canyon, and expects to start shipping at an early date. J. C. Sartorius is president, and J. V. Runnsen, vice-president.

Tuolumne County

(Special Correspondence.)—J. W. Mercer of New York, has exercised his option on the Poison Oak mine, and has taken

CYANIDE PLANT, MELONES MINE, CALAVERAS COUNTY, CALIFORNIA.

it over on a lease and bond. Development has been started under the supervision of W. H. Knowles of Sonora. This mine has been idle for about 15 years. The former owners sunk an incline shaft on the vein to a depth of 300 ft. Three levels were opened, all showing good ore. A five-stamp mill was erected, and about 5000 tons of ore crushed. As depth was attained the ore became more mineralized, and the recovery by amalgamation decreased. While part of the gold was saved by concentration, a great deal went down the creek in the tailing. In those days the concentrate was hauled by wagon to the nearest railroad, and shipped to the Selby smelter. Electric power was not in use in this county, and other modern methods of mining and milling were unknown at that time.

There are other deals pending in the district.

Sonora, January 2.

The McAlpine Mines Co., an organization of Californian people, has been formed to re-open the old McAlpine mine near the line between Tuolumne and Mariposa counties, the nearest town being Coulterville. F. R. Whitcomb is president and manager, L. C. La Rue is vice-president. The mine was worked in the 60's, and was a well-known producer in the early days. A shaft has been sunk 500 ft., and some development done toward re-opening the old workings. Electrical machinery will be installed.

COLORADO

Clear Creek County

(Special Correspondence.)—An 18-in. shoot has been cut in the Lake vein by Craise & Co.; the first carload shipment

settled for 5.4 oz. gold per ton. Work is done through the Big Five adit, and at the bottom of a 50-ft. winze.——The 1915 production from the Edgar and Bellman veins of the Big Five company totaled $34,780. These were the only two properties worked by the company.

All preliminary work at the McClelland adit has been completed, and machine-drills are at work. Progress is expected to be at the rate of 150 ft. a month. L. W. Shaffer is manager.

Eighteen inches of ore has been cut in the east drift of the Ruler vein at Georgetown, worth $100 per ton in gold and lead. Work is done from the Capital adit.

It is reported that the Onondago Mining Co. will take over the Doric property on Saxon mountain. The adit has a length of 3009 ft., but it is proposed to drive 2000 ft. to intersect the vein system of Highland park.

Harper & Co., leasing on the Aetna vein at the Capital mine, has commenced shipments of $80 ore. The shoot is 10 in. wide.

Idaho Springs, December 29, 1915.

Ore production of the East Argentine district has averaged 24 tons per day during the past two months, the largest recorded. The largest shipments come from the Imperial mine. All lessees are getting satisfactory returns.

TELLER COUNTY (CRIPPLE CREEK)

Work has been resumed at the Black Belle company's property on the east slope of Beacon hill. The Chester Leasing Co. has a lease on 17 acres. Shipments will soon commence.

GEORGIA

LUMPKIN COUNTY

Thirty stamps are crushing hard ore from the Findley Ridge Mining & Power Co.'s Crown Mountain mine. A cyanide-plant, in charge of A. H. Head, is being erected.

Black sands from the Briar Patch placer claims are being investigated; they assay up to $200 per ton.

Encouraging developments are reported from the Stoudard, Calhoun, Consolidated, Turkey Head, and other properties.

IDAHO

CUSTER COUNTY

The town of Mackay was started by the owners of some copper mines nearby, and has grown considerably. The Empire mine is of some importance, managed by Ralph R. Osburn. Utah people, headed by L. R. Eccles, now have control. Frank M. Leland is consulting engineer.

In the Yankee Fork district the Custer Slide & Development Co. operates the Montana mine. Two weeks ago 27 tons of ore was brought to Mackay from this property. Of this, 6.5 tons is worth $15,000, and the remainder, $350 per ton. The mine is well equipped.

SHOSHONE COUNTY (COEUR D'ALENE)

In *The Wallace Miner* of December 30 are some interesting figures on 13 years' mineral production of the region, also the estimated output of the State in 1915, the latter compiled by the state mine inspector, Robert N. Bell. His total value is not much different from that of the U. S. Geological Survey, but the outputs vary somewhat. He estimates as follows:

Metal.	
Copper, pounds	6,655,000
Gold, value	$1,235,000
Lead, pounds	364,300,000
Silver, ounces	12,206,000
Zinc pounds	91,731,000
Total value	$37,551,542

The Coeur d'Alene produced 95% of the lead and 98% of the zinc. Custer county yielded 95% of the copper, and Boise county 50% of the gold. Most of the antimony came from the Coeur d'Alene.

Employees of the mining companies were well treated during the holidays, along with the days off they were given turkeys and cigars by some.

The Morning-Evening vein of the Federal company's Morning mine is expected to be soon cut by No. 4 adit of the Independence Lead Co., which is in 3000 feet.

The Washington Water Power Co. reports that it has made contracts for power with 22 mining companies in the Coeur d'Alene since last July. Others are awaiting connection.

ILLINOIS

(Special Correspondence.)—Large shipments of zinc ore continue to be sent from the Black-Jack, Federal, Kohlmann, North Unity, Great Western, and Joplin producers at Galena. A new separating-plant, built by the Great Western company, is treating a stock-pile, making four cars of top-grade product each week. The Galena Refining Co. has purchased seven acres of land in this city, and a new 75-ton separating-plant will be finished on January 1. The new plant involves new methods of electrolytic separation devised by L. V. Rice. All grades of ore can be treated at greatly reduced cost.

Galena, December 22.

MICHIGAN

THE COPPER COUNTRY

A brief review of this region appears on page 63 of this issue.

Over 1200 employees of the Mohawk and Wolverine companies received a 5% bonus at Christmas.

MISSOURI

JASPER COUNTY

Prices for zinc concentrate at Joplin during the week ended December 31 ranged between $85 and $116 per ton. The output of the Missouri-Kansas-Oklahoma region was 5473 tons blende, 808 tons calamine, and 1098 tons lead, averaging $96.70, $64.10, and $67.06 per ton respectively. The total value was $622,830, and for 52 weeks, $25,268,783. Another week's return will complete the past year.

The 'Origin of the Zinc and Lead Deposits of the Joplin Region' (Missouri, Kansas, and Oklahoma), is the title of U. S. Geological Survey Bulletin 606 by C. E. Siebenthal. The publication covers 283 pages. The author has been studying the deposits for 12 years, although not continuously. The work is very thorough, and should be secured by all interested in the area which produced the large total as given above.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The East Butte Copper Co. is negotiating for control of the Butte & Duluth property, which has been tied-up in bankruptcy for several months. The claims are near the Pittsmont mine and smelter of the East Butte. The ore contains copper carbonate and is mined by means of an open-cut. The mill has a capacity of about 250 tons per day. The ore was crushed through 8-mesh and leached with sulphuric acid in a series of five large Dorr classifiers. The copper was precipitated by electrolysis. The mill was completed only a short time before the shut-down, and the company was not strong enough to work in the face of the low price of copper and the general depression that existed at that time. The process was successful, however, and there is every indication that the property can be worked at a profit.

The Butte & Bullwhacker has been leased to Patrick Wall and I. A. Heilbronner for one year, under the condition that they mine at least 1000 tons of ore per month, and pay as royalty 25% of the net proceeds. They also secured an option on 51% of the stock of the company at 50c. per share. The first payment is to be made in 30 days, the second in 90 days, and the final payment at the end of 18 months. The Bull-

whacker is near the Butte & Duluth, and it was also worked by a glory hole. About $400,000 was spent experimenting with leaching processes similar to that adopted by the Butte & Duluth. But as the copper occurs as a silicate, they were not successful. Former lessees have made money shipping the high grade ore to a smelter.

Butte, December 24, 1915.

NEVADA

Humboldt County

A 50 ton concentrating-plant is to be erected by the Antimony Syndicate Co., near Unionville. The ore is high grade. John Ross is superintendent.

Little has been heard from National lately, but it is now reported that the National Mines Co. has installed a tube-mill and is shipping concentrate.——The Indian National, Snorting Bob, Shilo Mining, and Howard and Hudelson companies are busy with development.

At 60 ft. below the 1400-ft. level the Seven Troughs Coalition company has cut two feet of $240 ore, showing plenty of free gold.

Nye County

Six companies and several lessees at Tonopah last week produced 7567 tons of ore worth $162,166.

The Tonopah company shipped 60 bars of bullion valued at $72,225. Development generally is satisfactory.

The Extension profit in November was $61,800.

The Nevada-California Power Co., which supplies Tonopah with electricity, has insured its employees for $1000 each in the Equitable Life, and will keep the policies in force at its own expense. A benefit fund is also being arranged.

Kansas City people, connected with the Tigre Mining Co. of Sonora, Mexico, have purchased the Phonolite claims three miles west of Ione. E. C. Cooey represented the purchasers. A mill is contemplated at an early date.

SOUTH DAKOTA

Lawrence County

Two weeks ago the Wasp No. 2 company sent 26 tons of tungsten ore to the Crucible Steel Co. of America at Pittsburg. The lot is valued at $48,000.

Pennington County

If sufficient money can be raised, the Hill City Mining & Development Co., will sink its shaft, develop the mine, and erect a 100-ton mill. A persistent vein has already been opened to a considerable extent. The property is five miles north of Hill City.

TENNESSEE

Polk County

A much greater output of zinc is expected from the Mascot mine of the American Zinc, Lead & Smelting Co. during 1916 than in 1915. The total may be 45,000,000 lb. The 10 months ended October 31, 1915, produced 386,880 tons of 3.99% ore, yielding 18,741 tons of 59.88% zinc concentrate equal to 22,444,000 lb. of metal. The estimated cost is 4.05c. per lb. The present daily capacity of the mill is 2600 tons of ore.

UTAH

In its issue of January 2, *The Salt Lake Tribune*, devotes 88 pages to a review of the year, etc., in this State, the mining section covering 10 pages including carefully prepared statistics, brief notes on the mines, districts, processes, and power development.

Juab County

The Colorado Mining Co. has issued its report for the year ended November 1, 1915. The property at Tintic was worked mostly by lessees, which resulted in a net profit of $9914 to the company. When the Tintic Milling Co.'s new plant is ready, probably in January, the low grade ore will be treated there. The lessees' output was 1490 tons (dry) of ore assaying $36.15 per ton in gold, silver, lead, and zinc. Sampling, freight, and treatment cost $8.42 per ton. The cash balance is $42,054. J. W. Knight is general manager, and E. F. Hirch assistant.

Salt Lake County

The Bingham Tooele Mining Co.'s adit is in 572 ft. in heavily mineralized formation. The flow of water is increasing. Officials expect interesting developments in the near future.

Summit County

The Ontario company is now shipping 50 tons of ore daily from its 1000 and 1500-ft. levels to the Garfield smelter. It is highly siliceous.

PART OF UTAH, SHOWING ALUNITE DEPOSITS. THE U. S. GEOLOGICAL SURVEY RECENTLY ISSUED A BULLETIN DESCRIBING THEM.

WASHINGTON

Ferry County

(Special Correspondence.)—During the last seven weeks the following shipments of ore have been made from mines at Republic: Ben Hur, 2960 tons; Tom Thumb, 765; Knob Hill, 480; and Lone Pine, 400; a total of 4605 tons.

Work has been resumed in the Belcher mine in the Belcher district, with a few men and shipping three to four cars of ore per week.

Lessees have been extracting $25 ore from the Washington mine, on Belcher mountain, and are now developing an extensive body of pyrrhotite, which gives small returns in gold.

Information from Keller states that a five-foot vein in the Golden Crown mine is producing ore assaying $234.80 in silver, copper, and zinc, with enough gold in addition to pay the cost of treatment. The mine is owned by the Illinois Copper-Silver Mining & Milling Co. Andrew Hamilton is the local manager.——Four miners are working on the Walla Walla group, and recently struck a stringer of high-grade copper ore a foot wide.

Republic, December 25, 1915.

Okanogan County

Following a request made by the Northwest Mining Convention held at Spokane last February, F. A. Thomson, head of the mining department of the Washington State college at Pullman, has made an investigation of the mineral deposits in this county. He states that there are in this district bodies of more or less complex ore, consisting mainly of pyrite, sphalerite, galena, and tetrahedrite, all contained in a gangue of

blnish-white quartz. He has not been able to make a thorough investigation of the deposits in the district and consequently cannot report on the quantity of ore available, as the State government, unfortunately, while it makes liberal appropriation for research work in other lines and industries, does not provide funds to finance investigations of the mineral resources. For this reason he was compelled to confine his efforts to devising treatment methods. In this Mr. Thomson feels that he and his assistants have been successful, having made a series of exhaustive tests in the college laboratories. While this investigation has not been carried far enough, as yet, to justify final conclusions or specific recommendations, it is evident that local treatment can be provided that will yield satisfactory results. The choice so far appears to lie between a light chloridizing roast, followed by cyanidation after water-wash, and flotation concentration of all the ore, after crushing to 80-mesh. Each of these methods shows an extraction by laboratory test of approximately 90% of the silver and a large proportion of the copper. The flotation method, of course, yields a concentrate which must be either shipped to smelter or treated further at the mine. It seems probable that an application of the light chloridizing roast with water-wash, followed by cyanidation, which has proved successful with the ore, might be applied to the flotation concentrate with equal or greater success. This point will shortly be investigated.

Spokane County

Mining companies operating in regions tributary to Spokane paid a total of $10,560,060 in dividends last year, making $83,285,455 to date.

Stevens County

Negotiations are pending for a lease and bond on the properties of the American Tungsten Consolidated Corporation, 25 miles west of Springdale, and about 50 miles north-west of Spokane, by Eastern interests, represented by Fletcher T. Hamshaw of Seattle. It is thought the deal will be closed shortly. Men and supplies are now being sent into the camp to prepare accommodations for a crew of 100 men, who will be at work, it is thought, in the next 30 to 60 days. The mill was dismantled several months ago, but it is said that the building is in good condition to receive new equipment that is reported to have been ordered, and that the installation will be completed within 30 days, provided the heavy machinery can be transported to the property. Ten four-horse teams have been secured to haul ore from the mine, and that until the mill is ready to operate crude shipments will be made regularly. Not less than a car daily will be forwarded to the smelters, beginning about January 10. The workings consisting principally of three adits, aggregating about 3000 ft., are said to have exposed a considerable quantity of ore.

WISCONSIN

Grant County

(Special Correspondence.)—At Hazel Green the McMillan Zinc Co. is down 140 ft. in ore. An initial shipment of hand-cobbed ore will be made before January 1. A complete separating-plant is nearing completion.——The Monmouth Zinc Mining Co. has a 7 by 11-ft. shaft well under way. Mechanics have begun construction of the main power and mine plant, to be ready by March 1.——Regular weekly shipments continue from the Kennedy, Cleveland, and Lawrence mines. Several tracts have been drilled out with success.

At Platteville the Wisconsin Zinc Co.'s Empire roasting-plant, after continuous operation for six years, will be closed on January 1 and the plant removed. The Klar-Piquette mine, at one time paying 350% dividends per year, has resumed and is shipping heavily. Two dividends have been paid this year. ——The West Hill Mining Co., with a small capital, has paid 150% in dividends this year. Local interests have carried the brunt of new mine development and equipment in this district in the past year. Tremendous strides have been made in this field, as is shown by the number of new plants completed recently, namely, 32, with a total capacity of 6825 tons.

The National Separating Works at Cuba is running at high capacity, regularly treating 700 to 800 tons of crude ore per week. Shipments of 61% ore are made at the rate of 8 to 11 cars.

Platteville, December 22, 1915.

Iowa County

(Special Correspondence.)—The Highland district, well known for extensive deposits of carbonate of zinc ore, is languishing for want of a demand for the product. Thousands of tons of ore ready for shipment are held.

The New Jersey Zinc Co. is preparing to mine new deposits of blende on the Kennedy farm. A new two-compartment shaft is nearing ore. A 250-ton power and milling-plant will be provided this winter. Electric power recently available in this district, gives an incentive to extend operations.

The Linden Separating Works is making the highest-grade product of the field, namely, 62%.

The new acid department of the New Jersey Zinc Co.'s plant is returning one 25-ton tank car of commercial sulphuric acid per 24 hours. The supply is consigned to the Atlas Powder Works, at Senter, Michigan. The New Jersey Zinc Co. has begun the construction of a new zinc-ore roasting and separating-plant of 150-ton capacity. The present equipment is inadequate. Five Mathey hearths are now at work on ores mined from the New Jersey company's mines in this field.

The Peacock Mining Co., operating the Peacock mines in the Mifflin district, has paid to shareholders of record for 1915, 75% in dividends.

Eastern mining syndicates have representatives in this district reporting on leaseholds and fees available for zinc-mining. This district, practically eliminated from mining reports early in the year, has jumped into second place, shipping from 20 to 30 cars of zinc ore per week. Milwaukee capital is heavily interested. The Coker mines, owned by the New Jersey Zinc Co., continue weekly shipments of from 10 to 15 cars.

Mineral Point, December 22, 1915.

LaFayette County

(Special Correspondence.)—The high-water mark has been reached at Benton in producing 50 cars of crude ore in a week.

The Fields Mining & Milling Co. has installed new crushing machinery, facilitating the handling of 750 tons of mill-rock, each 20-hour mill run.

The Vinegar Hill Zinc Co. has a new shaft in ore on the Blackstone lease of 160 acres and a new plant will be started on January 15.

Local interests, including four of the leading mining operators of the district, have a road-building project under way, to give all outlying producers track facilities during all seasons. The C. & N. W. R. Co. offers to contribute $20,000 if mining men will pledge their traffic in return for this aid.

Benton, December 22, 1915.

CANADA

British Columbia

(Special Correspondence.)—In the Windermere district of north-east Kootenay, Burgess & Co., who last summer bonded the Lead Queen claims situated on No. 3 creek, has just finished building 14 miles of sleigh-road, and about ¾ mile of rawhide trail to the mine, and is preparing to ship ore. The first 100 tons will be on the way before the end of the year, after which a steady production will be kept up; the expectation of the bond-owners is to ship at least 100 tons per week during the winter. There is a large tonnage opened in the mine, assaying well in lead and silver.

Negotiations were on foot earlier in the year to re-open the Paradise mine, but they have not yet materialized. This mine shipped approximately 2000 tons of lead carbonate ore

of high lead value, and good silver content, some 10 years ago. There is a lot of second class ore assaying from 20 to 30% lead, and 20 to 30 oz. of silver, on the dump. The above ore was chiefly taken out in development, and in the mine there is a correspondingly large amount of both first and second class ore blocked out. Transportation difficulties, owing to lack of railways, and inefficient boat service only in the summer months, caused the shutting down of the mine at that time. The building of the Kootenay Central railway through the upper Columbia and Kootenay valleys has done away with these hindrances, and will enable the mine as well as many others in the district to make fine profits. Lack of capital to open them is the drawback at present, and here is a good field for the investor. The ores are chiefly lead-silver, with some copper in the form of tetrahedrite.

Wilmer, December 22, 1915

The Standard Silver-Lead company's profit in November was $99,039, from a revenue of $136,278. The balance on November 30 was $336,397.

The Slocan Star company will probably issue $100,000 7% bonds to finance improvements at the property. An aerial train 4000 ft. long, from the mill to Sandon, is to be ordered.

The Tonopah Belmont Development Co. of Nevada has decided to complete its option on the Surf Inlet mine on Princess Royal Island. A hydro-electric plant, 250-ton mill, and other machinery is to be erected.

In the January 1, 1916, issue of the *Journal of Electricity, Power, and Gas*, San Francisco, is a condensed report on the water-power plants of the Province taken from the original by G. R. G. Conway for the Dominion government. The Province has a superficial area of 372,640 sq. miles. The drainage from the mountains and highlands is received in numerous lakes, their surplus water flowing to the sea by several large rivers or their tributaries. The principal rivers are the Columbia, Fraser, Liard, Peace, Skeena, and Stikine. Development of water-power on a fairly large scale began in 1897. The present capacity of 16 large and several small concerns is 230,000 hp. Those supplying the mining industry have an output of about 50,000 hp., the Britannia, Canadian Collieries City of Nelson, Granby, Hedley, and West Kootenay.

MEXICO

El Oro

Esperanza Limited has issued a report for the period July 1 to September 30. Development amounted to 921 ft. Milling work has not been resumed, as there has been no improvement in the political situation. El Oro is still cut off from the outside world, as there is neither railroad nor telegraphic communication. During the quarter several suspensions of power occurred, caused by troops of the opposite party from that which might be occupying El Oro at the time. In September the mine was without power for two weeks at one time. In August, acting upon a peremptory order from the Governor of the State, all wages payable in Mexican currency were increased 50%. This order was absolutely uncalled for, as there had been no difficulty over wages—on the contrary, arrangements had been completed whereby the workmen should receive increased pay, and be furnished with the most common of foodstuffs at cost. At the end of the quarter 90% of weekly pay-rolls is being given to the laborers in food, as there is no food in the camp aside from that brought in by the mining companies.

Later advices from the mine state that "the local as well as the general political situation has 'cleared up' remarkably during the past month. Trains are now running daily between El Oro and Mexico City and mail and food supplies are coming in."

During December the San Francisco Mint received 359,572.383 oz. gold, and 65,886.43 oz. silver. Coinage executed was worth $2,199,030.

PERSONAL

Robert E. Cranston is at Butte.

S. A. Jones was at Spokane this week.

Charles E. Knox was in New York recently.

Hon. H. Thayer sails for Chile on January 15.

Whitman Symmes is at Thermopolis, Wyoming.

John H. Baker of Phoenix is at the Palace Hotel.

Chas. A. O'Connell is at Santa Barbara, California.

Arthur R. Wiggall and H. R. Bostwick are at Denver.

F. R. Wilkes has returned to New York from California.

R. M. Raymond has returned from London to New York.

T. J. Jones has returned from Kyshtim, Siberia, to London.

Ralph Arnold has returned to Los Angeles from Venezuela.

Leo Von Rosenberg recently visited the Ray district, Arizona.

Ernest Williams is on his way from London to South America.

W. H. Bassett is visiting the Miami and Inspiration mines in Arizona.

F. H. Mason has gone to San Diego with the Canadian mineral exhibit.

L. D. Ricketts sails from New York for South America on January 15.

A. N. Mackay is now manager of the Frontino & Bolivia mines in Colombia.

W. J. Loring has returned from a visit to Angels, California, and opened an office in the Crocker building.

G. D. Hirshberg and M. N. Zinberg sailed from San Francisco on their return to Russia, on January 6.

Hoyt S. Gale of the U. S. Geological Survey has gone to Chile and Peru on three months' leave of absence.

Sumner S. Smith, Federal mine inspector for Alaska, is visiting Washington, D. C., before returning to Juneau.

H. S. Mulliken has been appointed manager of the mines and smelter of the Peñoles company at Mapimi, Durango, Mexico.

George B. Butterworth, manager of the Whim Well copper mines in Western Australia, visited Anaconda on his way to London.

James J. Carrigan, safety engineer for the Anaconda company, has been appointed assistant mining superintendent of the company's zinc mines at Butte.

George P. Coffey, of Oakland, superintendent of hydraulicking for the Yukon Gold Co. at Dawson, Klondike, is at the St. Francis hospital recovering from an operation for appendicitis.

Albert G. Walkins, for eight years a foreman at the Copper Queen property, Arizona, was killed underground on December 29.

John T. White, well known at Joplin, Missouri, died on December 30. He was well versed on the geology and mining of this region.

Bulletin 3, series H, of the Mackay School of Mines at Reno, is the alumni number, with short addresses by the president, Archer W. Hendrick, Ellsworth R. Bennett, and F. C. Lincoln. The secondary mining schools at Virginia City at Tonopah are under the supervision of this institution. One hundred and thirty-six men have graduated from the Mackay school, of whom 10 have since died; of the remaining 126, more than one-half are in Nevada, one-quarter in California, and one-tenth in foreign countries.

THE METAL MARKET

METAL PRICES

San Francisco, January 6.

	Cents per pound.
Antimony	40
Electrolytic copper	25
Pig lead	6.00—6.95
Quicksilver (per flask)	$150
Spelter	20
Tin	45
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, January 6.

Antimony: no change; 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica, per ton	12
Magnesite: crude, according to quality and quantity, per ton, f.o.b.	7.50—10
Magnesite: plastic, no iron and lime, calcined, per ton	50
Magnesite: refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Manganese: 80% metal, f.o.b. New York, per ton	70
Tungsten: minimum 65% WO_3, per unit for spot	35—45

At Boulder, Colorado, on January 2, 60% tungsten ore realized $45 per unit.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 6.—Copper is very strong, with spot metal becoming scarce; lead is very strong and active; zinc is quiet and easier.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

On January 4 the Bunker Hill & Sullivan paid dividend No. 221, of $81,750.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Tin is strong at 44 cents.

ANTIMONY

Good inquiries have developed, some of which have culminated in business, and whereas the market was easy last week at 39 to 39.50c., duty paid, it is now strong at 39.50 to 40c., for Chinese and Japanese grades. Spot is scarce and higher prices are looked for, if the pressure of demand keeps up.

The revolution in China, especially in the antimony province of Hunan, may affect prices later on.

Eastern Metal Market

December 20, 1915

Copper has held the centre of the stage, and so far as buying is concerned has outstripped all the other metals. The excitement started by Great Britain's big purchase of a week ago has been sustained until now. Zinc has not shared the activity, but is firm at last week's price. Lead is extremely strong, principally because of the heavy export demand. Tin quotations have changed but little, and most of its activity has been in futures. Antimony is higher and active. Aluminum has had a dull week and quotations are easier. Sheet copper is now quoted at 27c. base. Early this week some of the independent brass mills withdrew quotations on their products. So winds up a year that has been a good one for the metal trade, but its prosperity has been based entirely on the War demand, although it is true that in the last few months domestic demand improved considerably. Copper exports of December made a good showing compared with previous months.

The congestion of foreign bound freight at the port of New York because of the lack of cargo space on trans-Atlantic vessels shows little improvement, although the French and English governments and their agents are straining themselves to get vessels here to relieve the situation. The steel mills are receiving fewer domestic specifications, one reason being that when last quarter contracts are concluded, new ones become effective which were placed at advances of several dollars a ton. Consumers who bought steel at 1.20c., Pittsburg, will henceforth have to pay 1.80c., or more. Many foundries in the East have been crippled by a shortage of coke, due to the railroad tie-up, and one blast-furnace has been banked for the same reason. Tin-plate for export has been in heavy demand, especially from the Far East, and contracts for the year have been made on the basis of $3.80 per box.

COPPER

The purchase of 120,000,000 lb. of copper a week ago by the British government not only caused great excitement, but started a rush of buying on both domestic and foreign account that is not yet ended. Domestic consumers have bought heavily for first and second-quarter delivery, and some of the large selling-agencies are now saying that they have but little metal to sell this side of April. It is understood that the big deal was shared by the United Metals Selling Co. and the American Smelting & Refining Co. Under the influence of this demand quotations have advanced from day to day, and sometimes from hour to hour. Electrolytic is now 22.25 to 22.50c., full terms. Lake is nominal at about the same figure, as none is to be had. That copper should reach its highest point in the last week of the year was unlooked for, and members of the trade are of the opinion that almost anything may be expected. Predictions that the price of copper will go to 25c. are commonly heard. Some of the independent brass mills withdrew prices on their products, Monday of this week, but sheet-copper is to be had at about 27c., base. Wire drawers and the brass mills have been more liberal purchasers of late than at any previous time in the year. After a three-day Christmas holiday at London the quotation there for electrolytic advanced £4 to £107, which is about equal to 22c. landed in England. On December 29, the London quotation went to £108. The exports of this month are the best since last March. Their total, up to December 30, was 29,694 tons, whereas in March they were 30,148 tons. There is more and more talk of a scarcity in copper, but as to the real likelihood of such a situation none but the producers know, as since the dissolution of the Copper Producers' Association authoritative statistics are not available to the general public, or the buying public, for that matter. Whatever the state of stocks, the outlook is good for the trade. The National Conduit & Cable Co. says in 'Copper Gossip':

"The pronounced expansion in American consumption of copper during the last half of this year establishes a new high record for domestic melting. This feature of the situation has created an unusually interesting and strong market. Manufacturers have been able to operate their plants to capacity recently. Urgent demand for manufactured material and shapes naturally created a big market for raw copper. With the consuming trade extraordinarily busy, the development of strength and activity in copper followed as a matter of course. And it is an encouraging fact that there are signs indicating substantial operations in manufacturing enterprise during 1916."

ZINC

This metal has not shared the excitement which has prevailed in copper, a fact which is rather contrary to precedent. One reason for this is the heavy buying of a few weeks ago, while another is that the holidays at London included Monday. About December 24 offerings became a little freer and the quotation for spot dropped a few points, but recovered after the Christmas holiday, and 17.50c, New York, again was quoted. Prompt metal continues scarce. The London market on December 28 and 29 was quoted at £90 for prompt. There is some good inquiry in this market for prompt and near-by, but consumers continue to hold themselves aloof from future deliveries. February is quoted at 16c., March at 15.50c. and second quarter at 14 to 14.25c. Exports from December 1 to 30 total 5691 tons. Sheet-zinc, in carload lots, is unchanged at 22c. f. o. b. mill, 8% off for cash.

LEAD

There is little to say about lead, save that prices are strong, and predictions of an advance are heard on all sides. It has been repeatedly observed, however, that lead prices often move just the opposite of what is expected. At the same time there can be no question as to the strength of the market, inasmuch as independents are getting from 2½ to 5 points over the quotations of the leading interest, which continue at 5.40c., New York, and 5.32½c., St. Louis. The London market has been quiet because of the holidays, but is strong at £29 10s. Re-sale lots have pretty well disappeared from the market. Exports continue a strong phase of the situation, as evidenced by an offer of 5.50c., New York, for 500 tons for January export shipment, an offer which was turned down. Exports would be heavier were it not for the scarcity and high cost of ocean freight-space. Conditions have reached a point where only the allied governments can be half way certain of getting freight room. With them it is a necessity. Exports to date this month total 6654 tons.

TIN

Business of late has been almost entirely in tin afloat or shipment from the Far East. On various days trading aggregated from 150 to 300 tons, all in futures. Sellers are few. It is a question to what extent Great Britain will permit direct shipment to America from the Far East. Its restrictions of a few months ago indicated that it intended to keep a strong hand on the supply, and already reports are current that it may cut down tonnages intended for direct shipment, preferring that shipment be made by way of London. The spot quotation on December 29 was 39.50c. The quantity afloat on the 30th was 5618 tons, and up to that day 3922 tons had arrived.

Metal Production in 1915

The U. S. Geological Survey has issued its preliminary statements regarding the mineral output of certain states, from which the following is abstracted:

CALIFORNIA

California mines show a materially increased output in gold, silver, copper, lead, and zinc in 1915, compared with 1914, according to preliminary figures compiled by Charles G. Yale. The mine figures for 1914 were $20,653,496 in gold, and 1,471,859 fine oz. silver; the estimates for 1915 indicate an output of $22,860,590 in gold and 1,974,529 oz. silver. California remains the premier gold-producing State of the country. The yield for 1915 is, with one exception, the largest in any year for 51 years, and is the largest for 32 years. There are about 700 producing metal mines in the State, about evenly divided between deep and placer mines of various kinds. About 2,500,000 tons of ore is mined and treated in the State annually of an average value in all metals of $6.75 per ton. In value of all metals produced, Shasta is the leading county, while in value of gold output, Nevada, Amador, Yuba, and Sacramento are the leading counties in the order named.

Dredges are producing 86% of the placer gold. During 1915 there were 67 boats in operation and 60 at the end of the year.

The yield of copper was 44,098,552 lb., compared with 30,507,692 lb. in 1914.

The mine output of lead in 1914 was 4,251,923 lb.; in 1915 it is estimated at 6,346,319 lb., Most of this is derived from the southern counties of the State, particularly Inyo county.

The zinc output is 11,443,926 lb. against 389,471 lb. in 1914, an increase of 11,054,455 lb. This is the largest production of this metal ever made in California in one year. The greater proportion was derived from Shasta county, where one of the large copper smelters has installed a zinc-sorting plant. Inyo county was also a large contributor to the zinc output of the State.

OREGON

Preliminary estimates made by Charles G. Yale show material increases over the figures of 1914, in both gold and copper, and nominal decreases in yield of silver and lead. The gold yield for 1915 was $1,771,618, an increase of $180,157. The silver output was 136,033 oz., or 6519 oz. less. The yield of copper was 910,104 lb., an increase of 870,856 lb.; and the yield of lead was 6650 lb., or 9786 lb. less than in 1914.

It is noteworthy that such material increases in output of gold and copper should be apparent when the fact is considered that the number of producing mines in Oregon has fallen off fully one-third in the past two years. Baker county continues to be by far the most productive county of the State, yielding annually fully 85% of all the gold. Of the placer mines in Oregon, by far the most important enterprise is that of the Powder River Dredge Company, Cracker Creek district, Baker county. This company, which owned but one dredge in 1914, put another one in operation in the same field in 1915, and it is to the work of this company that the increase in gold yield in the State for the year is mainly due.

UTAH

Mines in Utah produced gold, silver, copper, lead, and zinc in 1915 amounting in value to $55,000,000, as estimated by V. C. Heikes. This represents an increase over the production in 1914 of nearly 50%, or $18,000,000. There was a considerable increase in all the metals. About one-fourth more ore was mined, increasing the total from 8,544,014 tons in 1914 to about 10,725,000 tons in 1915. About 9,900,000 tons was produced at Bingham, an increase from 7,800,661 tons in 1914. The bulk of this ore was mined at the Utah and Ohio copper properties, which yielded about 9,000,000 tons of low-grade ore in 1915. Other mines that contributed large quantities of ore were the Utah Consolidated, Utah Apex, United States, Bingham, Bingham New Haven, and Utah Metal mines. The Tintic district produced about 290,000 tons, against 298,486 tons in 1914. The main ore producers were the Chief Consolidated, Iron Blossom, Centennial Eureka, Eagle & Blue Bell, Mammoth, Gemini, Grand Central, and May Day mines. The 100-ton concentration mill, built primarily to treat Chief Consolidated ores, did considerable custom work.

In the Park City region about 99,795 tons of crude ore and concentrates was shipped, against 66,736 tons in 1914. Improvements in concentration methods resulted in large shipments of lead and zinc concentrate from the Daly-Judge, Daly West, and Silver King Coalition mills.

The mine output of gold increased over 19%, from $3,265,347 in 1914 to $3,908,000 in 1915. Copper ores yielded the larger part of the gold but large quantities also came from lead ore and silicious ore.

The mine production of silver increased from 11,154,916 oz. in 1914 to approximately 12,724,000 oz. in 1915, the increase amounting to 14% in quantity and about $169,000 in value. Much of the silver is derived from lead ore, and smaller quantities from the copper and silicious ores.

The copper output from Utah mines increased from 152,034,002 lb. in 1914 to about 182,589,000 lb. in 1915, the increase amounting to more than 20% in quantity and about $11,450,000 in value. The gain was made mostly by the Utah Copper mine at Bingham, which is credited with an increase of 34,207,552 lb. over the output of 1914.

The mine production of lead increased from 171,323,137 lb. in 1914 to 219,098,000 lb. in 1915, or about 28%, mostly from the Bingham district.

With the advance in prices, zinc ore was offered from many sources. The mine production of zinc recoverable as spelter aggregated 22,643,000 lb., valued at about $3,224,000. This is an increase of about 41% in quantity over the output of 1914, amounting to 15,989,267 lb.

All the smelting establishments were operating at full capacity soon after the first of the year. These were the Murray, Midvale, International, and Garfield plants.

Dividends amounting to about $9,000,000 were distributed by Utah mining companies in 1915 and $7,431,017 in 1914.

PETROLEUM

Preliminary estimates of the total yield of petroleum for 1915 indicate a slight increase over the record-breaking yield in 1914. This condition does not agree with the currently reported reason for the exceptionally high prices now prevailing for motor fuel.

As a result of the over-load put on the transporting and refining phases of the petroleum industry by the excess output of crude petrolenm in 1914, the year 1915 may be characterized as a period of re-adjustment, in which production activity was purposely retarded as far as practicable. The small increase therefore is more significant than the simple figures suggest.

According to John D. Northrop the marketed production of petroleum in the United States in 1915 approximated 267,400,000 bbl., and the total yield approximated 291,400,000 bbl., about 24,000,000 bbl. of oil brought to the surface during the year being placed in field storage by the producers.

The following table shows by States the marketed production of petroleum in 1914 and an estimate of the corresponding production in 1915 in barrels:

State	1915	1914
California	89,000,000	99,775,327
Oklahoma	80,000,000	73,631,721
Texas	26,000,000	20,068,181
Illinois	18,500,000	21,919,749
Louisiana	18,500,000	14,309,435
West Virginia	9,000,000	9,680,033
Pennsylvania	8,700,000	8,170,335
Ohio	7,900,000	8,536,352
Wyoming	4,200,000	4,560,475
Kansas	3,000,000	3,103,585
Indiana	1,000,000	1,335,456
New York	900,000	938,974
Kentucky	450,000	502,141
Colorado	200,000	222,773
Other States	50,000	7,792
	267,100,000	265,762,535

The apparent increase in the quantity of marketed production in 1915 is accounted for by the continued output of oil in large quantities from the Cushing field, Oklahoma, during the first half of the year, and from the Humble pool, Texas, during the entire year, as well as by the discovery and rapid development of new pools in Louisiana and Texas.

The stocks of crude petroleum held by pipe-line companies at the end of 1915, amounted to approximately 195,000,000 bbl. including the oil retained in storage by certain oil companies that conducted a pipe-line business at the beginning of the year, but which business was taken over and later conducted by separate pipe-line companies. This reserve is approximately 50,000,000 bbl. greater than at the end of 1914.

Prices of crude petroleum at the wells were uniformly low in all fields from January to August, when the permanent decline of the Cushing field resulted in an increased demand for oil produced in other parts of the country, with a consequent advance in the scale of prices warranted. From the low level of $1.35 a barrel maintained from April 3 to August 14, 'Pennsylvania grade,' the market standard, advanced steadily during the last third of the year, reaching $2 on November 18, and $2.15 on December 17 and disclosed a strength which indicates a rapid return to the $2.50 level attained before the advent of Cushing. 'Kansas and Oklahoma' grade recorded an even more rapid recovery. From its low level of 40 cents maintained from February 15 to August 2, this grade advanced to $1.20 in a little more than four months, passing its former high level of $1.02 on December 13, and attaining the price above quoted on the following day. California grades were fairly steady throughout the year, a 5-cent cut affecting heavy oils in the Valley fields on June 7, and a corresponding advance affecting the same grade of oil on October 26, followed by a general advance of 2½ to 5 cents on all grades except Ventura county and Santa Maria, effective November 20.

Throughout the country as a whole, drilling activity was at a low ebb in all the developed fields until late in the year when the advancing market proved an incentive for a moderate amount of new work. The Cushing field, Okla., and the newer pools discovered as the result of wildcat drilling, during the year sustained a marked activity which was due to the conditions of local competition rather than to any justification expressed by the oil market.

ANTHRACITE production of Pennsylvania was 2,000,000 tons less than in 1914; shipments totaled 66,382,218 tons.

SULPHURIC ACID showed a large increase, 25%, the quantity being 4,007,000 tons of 50° acid.

IRON-ORE SHIPMENTS were 55,000,000 tons, against 39,714,280 tons. Portland cement increased 0.1% to 86,524,500 barrels.

Commercial Paragraphs

The SUNN CONCENTRATOR CO., San Francisco, has recently issued a pamphlet descriptive of its new pan motion batea amalgamator, giving instances of its application to placer and quartz mining.

With a cover illustrating the action of oil flotation in a tank, the DENVER FIRE CLAY CO. in Bulletin No. 150 briefly describes the process, and the Case laboratory flotation machine. A leaflet shows the Case oil-fired forge for drill-steel.

A. LESCHEN & SONS ROPE CO., St. Louis, send us the following: The Moctezuma Copper Co. has recently completed at Nacozari, Sonora, Mexico, the installation of a Leschen heavy-duty friction-grip aerial tramway. This is used for the disposal of tailing from the mill, it being 'wasted' along the line. The tramway is so arranged that the carriers pass around the outer terminal without detaching, so no labor is required at this point. The track ropes are 1½ and 1 in. locked coil, and the traction-rope ⅝-in. diameter of the patent flattened-strand construction. The capacity of this tramway is 50 tons of tailing per hour.—The United Verde Extension Mining Co. Jerome, Arizona, is installing a Leschen heavy-duty friction-grip aerial tramway for carrying its ore from the mine to the railroad. The line will be about 1000 ft. long, having a fall in this distance of about 600 ft. This tramway will have a capacity of 50 tons per hour. The carriers are of 10-cu. ft. capacity, and run when loaded on a 1⅜-in. diameter locked-coil track rope, and return on a track rope 1-in. diameter of the same construction. The traction-rope is ⅝-in. diameter of the patent flattened-strand construction.

The ROESSLER & HASSLACHER CHEMICAL CO., 100 William street, New York, has issued the following circular, entitled 'Cyanide': "Beginning January 1, 1916, we shall change the designations of our various grades of cyanide, basing same on sodium cyanide content. When the cyanides now in the market superseded potassium cyanide, the various grades of sodium cyanide were designated by their equivalents in potassium cyanide, in order to show their comparative strengths. Potassium cyanide 95-96% contains 38% cyanogen. Thus sodium cyanide containing 51-52% cyanogen was designated as 129%, that being its equivalent in potassium cyanide. Owing to its lower cost, sodium cyanide has now entirely replaced potassium cyanide in the recovery of precious metals, in fumigation, plating, etc., the results being equal if not superior to those obtained by the use of potassium cyanide. The lower cost of transportation is also an element of saving because of the greater cyanogen content of pure sodium cyanide. As potassium cyanide is no longer used, and the change to sodium cyanide fully understood, a re-naming of the different grades of cyanide is advisable. We shall label and sell sodium cyanide as such, and with the following we illustrate the change from the old to the new style of labeling and billing, and refer to the last page of the December issue of our price-list as to the actual wording of our labels:

Old designation.	Cyanogen content for both.	New designation.
Sodium cyanide..... 129%	51-52%	Sodium cyanide. 96-98%
Cyanide chloride mixture 98-99%	39-40%	Cyanide chloride mixture 73-76%
Cyanide chloride—carbonate mixture..28-30%	11-12%	Cyanide chloride—carbonate mixture No. 1
Cyanide chloride—carbonate mixture..38-40%	15-16%	Cyanide chloride—carbonate mixture No. 2
Cyanide chloride—carbonate mixture..48-50%	19-20%	Cyanide chloride—carbonate mixture No. 3
Cyanide chloride—carbonate mixture..58-60%	23-24%	Cyanide chloride—carbonate mixture No. 4

"We wish to emphasize particularly that we have not changed the composition of our products in any respect. The change is solely in the designation."

EDITORIAL

T. A. RICKARD, Editor

EXPORTS of copper continue heavy. Our New York correspondent reports that the market exhibits signs of strong support. Foreign demand persists with extraordinary vigor. Zinc is strong in sympathy and antimony is reported to be scarce. Lead also is strong, mainly on foreign account.

LITIGATION between the North Star and Empire mines at Grass Valley is likely to be avoided by a compromise, the particulars of which we hope to publish at an early date. The peaceful settlement of this intricate conflict of mineral rights does credit to the parties concerned and furnishes a good example to other mining companies in difficulty over their title by reason of an ambiguous law.

PROMOTION has caused Mr. H. M. Wolflin to leave San Francisco, in order to assume the duties of his new post at Pittsburg. We have heard many expressions of regret that he should have left this community, where he won the respect and confidence of those engaged in mining while acting for the U. S. Bureau of Mines on the Industrial Accident Commission. Mr. Wolflin had a difficult duty to perform and he performed it with a sincerity that commanded esteem.

ACCORDING to telegraphic dispatches, the striking miners of the three copper companies in the Clifton-Morenci district have withdrawn from the Western Federation of Miners at the insistent demand of the managements of these three mines. The men have applied for membership in the Arizona State Federation of Labor as a local union. This organization is affiliated with the American Federation of Labor. The concession thus made to the demand of the companies is credited to Mr. John L. Donnelly, of the executive board of the Arizona State Federation of Labor. Mr. Donnelly is to be congratulated on his public service. We hope that the incident presages further concessions and a speedy settlement of the dispute.

MINE transfers in California are being recorded with interesting frequency. The South American Mines Co., as related in our Mining Summary last week, has exercised its option on the Poison Oak mine in Tuolumne county, on the advice of Mr. J. W. Mercer. Another important deal is that whereby the old Eureka mine, in Amador county, passes from Mrs. Hettie Green to a group of mining men in New York. These strokes of business coincide with several highly satisfactory developments in deep mining on the Mother Lode. In the Kennedy mine a magnificent body of ore has been disclosed below the 3750-ft. level, and the Argonaut has been so successful in its deepest development work that a large hoist is to be erected at the 4200-ft. station of the incline shaft in order to continue systematic exploration downward.

ROBERT M. RAYMOND has been appointed Professor of Mining in the School of Mines, Columbia University, filling the vacancy created by the retirement of Mr. Henry S. Munroe. This appointment will excite keen interest and pleasure not only among the sons of Columbia but in the mining profession generally. Himself a graduate from the School to which he now goes as a professor, Mr. Raymond has had a wide, successful, and honorable experience not only in this country, but in Australia, Rhodesia, China, and Mexico. Born a Canadian, he became naturalized as an American in early manhood, thus coming back to the fold from which a progenitor strayed at the time of the Revolution. During recent years he has been manager and consulting engineer successively for the group of mines controlled by the Exploration Company, of London, in Mexico. Thus he brings thirty years of observation and experience to the lecture-room on Morningside Heights. And he has other qualifications fully as important. His soldierly poise and straight glance indicate a sincerity of purpose and directness of thought that will exert that moral influence without which the mere lecturer cannot be a real teacher. At a time when several professorships of mining are vacant and suitable selections are notoriously difficult to make, we congratulate our friends at Columbia on a choice so sagacious. We wish Professor Raymond every success in his new departure.

FORECASTS are more interesting than retrospects; perhaps on account of their hazard. The early days of this new year have brought us many opinions as t the future course of business and industry in the United States. One psychological fact is noteworthy: all the vaticinations assume the proximate ending of the War. The problem of the quidnuncs is as to what will happen "after the War." That is not a little remarkable at a time when there is no visible slackening in the intensity of the European conflict. Among so many optimistic statements, the warning issued by Judge Gary is not unwelcome. Danger is always near when everybody unites in prophesying smooth things. It is well that i should be realized that no precedents exist for any confident prediction as to the sequel of Armageddon. His-

tory furnishes no standard. Even the Napoleonic debacle affords no adequate experience. Credit has been extended to the fourth dimension. The wastage of men and material is stupendous. Our own trade has undergone an expansion that is altogether abnormal. The landmarks are gone; we are sailing in uncharted seas. Therefore we welcome the cautious tone of the memorandum published by the Secretary of Commerce and his insistence upon the need for better organization. The review issued by the National City Bank of New York likewise conveys some sound ideas, while emphasizing the check upon normal progress as the chief consequence of the War. To make real gains, the United States must use its productive powers and resources "with a new and extraordinary degree of co-ordination and efficiency." The *Annalist*, another sagacious observer, believes that the adoption of the Federal Reserve banking system came most opportunely, that the United States had just begun to look with increasing consciousness of power to business opportunities in foreign countries, and that the War has but accelerated that development. The wastage of war and the reconstruction in Europe will furnish an opportunity to the United States for extending help and so making a return for the assistance formerly given by the older countries in developing the natural resources of this country. In short, it is believed that the United States will emerge from the War period as a great creditor nation prepared to play the part that formerly centred at London, Paris, and Berlin.

Another Mexican Outrage

The latest performance of Mexican brigandage has created a keen feeling of resentment on the Pacific Coast, where the victims were well known and highly regarded. The demoralization of government on the south side of the Rio Grande has been brought home to the friends of Charles A. Pringle, W. J. Wallace, and the other Americans that have been killed under conditions of particular brutality. It appears that on January 10 a party of 19 men, including the staff of the Cusihuiriachic Mining Company, operating in western Chihuahua, was on its way from the city of Chihuahua to the mines by rail when the train was attacked at Santa Ysabel by a force of bandits led by José Rodriguez. These ruffians are reported to have stripped their captives naked and then shot them. The train carried a stock of supplies and silver currency to be used in the resumption of mining operations. It is stated that the party was traveling under the military protection of the *de facto* Government. One man escaped, Mr. Thomas M. Holmes, and from him the details of the atrocity have been obtained. The Cusihuiriachic company was one of the first to accept the promises of protection made by the Carranza government, and it remains to be seen what amount of responsibility is accepted by the Government and what steps are taken to catch the murderers. It is pitiable to read accounts of 'General' José Rodriguez, one of Villa's lieutenants. These military titles tend to cloak brutal assassinations under the guise of warfare, giving them a dignity that is monstrous. We do not wonder that a number of mining men at El Paso sent a telegram to Washington, reading, "The massacre of fifteen more American citizens in Mexico shows the result of a watchful waiting policy." It may not be logical, but it is intelligible. The President may reply properly that the men thus killed took their own lives in their hands by going to the mines at this time and the American government cannot be held responsible for their unfortunate fate. But this will be poor solace to their friends and relatives, who had the idea that the recognition of the *de facto* Mexican government involved an obligation to protect American citizens in the conduct of peaceful business.

Mining Education

Three pronouncements on this subject have been made recently: by Mr. William B. Phillips, the new President of the Colorado School of Mines, by Mr. John R. Allen, Professor of Mechanical Engineering in the University of Michigan, and by Mr. Charles F. Willis, Director of the Arizona State Bureau of Mines. In these discussions of the subject there is an evident struggle between the broad idea of a training that shall develop an effective citizen and the narrower concept of a specialized instruction that shall fit a young man to win bread and butter, and eventually wealth, in the competitive arena of an industrial civilization. Even the least expansive of professors understands, however, that no mining school can graduate either mine managers or smelter superintendents. Professor Allen quotes a wise saying: "No engineer was ever educated in a university, but the university has given many a man an excellent opportunity to educate himself." The motto of the school to which the present writer went as a boy was a saying in Latin that can be translated: "We do not learn for school but for life." Professor Phillips expresses the same idea when he says that "the training in such highly specialized matters as mining, ore dressing, and metallurgy is largely of a prophetic nature." It is impossible to foresee what the technical requirements of the future may be. The teacher can only elucidate principles by means of methods and processes that may be discarded by the time the student has barely started on his career. Professor Willis recognizes the rapidity with which conditions have changed in mining and metallurgical practice; he complains that the schools have lagged behind, retaining curricula that are largely obsolete. The theoretical mining engineer of an earlier era is no longer wanted, the commercial element now dominates the technical, so that science without business insight is quite ineffective. As industry becomes organized on scientific lines, it calls for technically educated men for every position of responsibility; not the captains alone, but even the corporals, must be properly equipped. We conclude then that to be effective the education must not be too specialized; what is needed is not so much the civil,

mechanical, or mining engineer, but an engineer *tout simple,* ready to adapt himself to conditions as they arise and to train himself for opportunities as they become evident. The European criticism is that the American is superficial but imaginative; he lacks thoroughness, but he is rich in adaptability. Part of this characterization is acceptable; the question arises whether some of the deficiencies cannot be corrected. In this, as in many other matters, Europe and America go to extremes both of which are faulty. Yet, in the end, all the efforts to reconcile divergent ideals will fail. You cannot eat your cake and have it. One ideal must be sacrificed to the other. A sane compromise is the only practical solution. The man who pursues the shekel unremittingly must not complain if his appreciation of sundry other good things becomes atrophied, as Darwin found his taste for music left him when he concentrated his days to grinding generalizations out of facts. So also the man of generous mind and philosophic temperament must not be surprised if he does not become a forceful driver of men or a successful collector of coins of standard value. Each presumably finds his happiness and each his usefulness. The genuine product of each school is better than the simulation of either.

The foregoing may seem an unsatisfactory answer to the question at issue. No reply can be completely satisfactory. Our own observation of men has taught us that they are too varied in their natural gifts and defects to respond to the same system of culture. To learn anything thoroughly is a mental training, to half-learn a dozen things tends to enfeeble the mind. A sound knowledge of Greek is a better preparation for engineering than an unsound schooling in electricity.

We find ourselves in quick agreement with Professor Phillips in attributing defective technical training in large part to the lack of a thorough teaching in mathematics and English. The one contributes to logical thinking and the other to clear expression; they react on each other, so as to combine in developing good habits of mind. Of course, the growth of the reasoning faculty is stimulated and developed by mathematics, but good teachers of this subject are rare. A firm hold of mathematics is essential to the engineer in obtaining a sound grasp of mechanics, just as a thorough understanding of the principles of chemistry is requisite to the intelligent development of metallurgical skill. As for the acquisition of a knowledge of the language, we can hardly lay too much stress on the importance of a control of, rather than a facility in, the expression of scientific thought. To know the English, or any other, language thoroughly is a liberal education. Not to be able to command the vehicle of ideas is to be handicapped in acquiring information for ourselves, no less than in giving it to others. While yielding to none in recognizing the paramount importance of a scientific training, we realize that the emphasis placed on the sciences has tended to cause a neglect of adequate schooling in English, the result being not only a lack of skill in writing and speaking but a loss of ability in the acquirement of technical knowledge. Much of what we learn comes to us in the form of the printed word, therefore the young man who has not learned thoroughly the language in which that printed word is given is handicapped in his effort to assimilate the knowledge that is provided by the literature of the period. The sooner it is acquired the better. It is the vehicle of thought in which all the other forces of written knowledge are conveyed.

Thus, the final conclusion is that no schooling is good that spoils sincerity of purpose. Inaccuracy of observation and statement is the dominant curse of a half-educated community and the mark of the half-baked engineer. No man can "see life sanely, see it whole" who deals in make-believe; none is worthy the name of engineer who has not learned that "there is no alleviation for the sufferings of mankind except veracity of thought and of action."

Individualism and Co-operation

The editorial under this title in our issue of December 4 has provoked an opinion as to the preservation of individuality in great organizations from no less a person than Mr. L. D. Ricketts himself. The ideas of a mine manager and consulting engineer of such wide experience on a subject so pertinent cannot help but be a matter of interest to both young and old members of the profession. Where is the corporation unit who does not at times chafe at the clumsy inertia of action and thought that characterizes large masses; in what mine staff or city office does not the question of the man versus the company play a constant and critical part? Yet all of us realize that co-operation is the secret of the success of American development in 'big business.' The specialization of useful effort, the co-ordination of unusual faculties, the utilization of spontaneous ability for the serving of the common good have come in this great undeveloped country to mean the binding together of diverse minds and varied capacities for an organization more than competent to compete on even terms with the industries of older and less well-paid peoples. We take pleasure in quoting herewith from the letter received from Dr. Ricketts, as he is generally known in the West: "In my opinion any organization that aims to prevent the expression of individuality will injure itself. My view-point is that an organization of large size requires a great many men in different capacities; that it is essential from top to bottom that a certain amount of personal effort be allowed to the employee, and that the more important the man the greater leeway should be allowed him. In taking up a study of a new process or the application of an experiment in commercial work, it has always been my practice to select a number of men, if necessary, to work out the details and the process. Each man should be given full swing, should be allowed credit for his work, and should be required to report his opinion. You must remember, however, that there are few men who have the qualities required for investigation and development, and at the same time possess

balance. As a consequence, someone with balance must review the work of the men under him, and, to the best of his ability, sort the practicable from the impracticable and see that the practicable points are developed, but if the work goes no further, both the investigator and the reviewer are apt to get in a rut so deep that they cannot see over the edge, and as a consequence other men must come in with fresh minds to discuss the problem, and throw side lights upon it. Then there must be someone with decision to adopt the plan and carry it out. I most thoroughly agree with you as to the tremendous importance of individualism and you appear to agree with me in the tremendous importance of organization and committee work. When, therefore, there are two view-points there must be a compromise, and the only compromise is the value of an efficient organization balanced in size to compare with the magnitude of the operation. Where individualism is curbed to a slight extent, and the organization evolves a final plan, the result of individualism may be apparently concealed, but if a well matured practical plan is studied in detail in all its branches, the individualism is bound to become apparent."

The statement of Mr. Ricketts needs no embellishment. He believes in the practicability of organization; he also believes in the genius of individualism. As he states: "When there are two view-points, there must be a compromise." Any compromise to attain the greatest degree of success—as measured in all its aspects—must be a careful balancing of the discipline, helpfulness, and bigness of organization with the imagination, originality, and personality of individuals. Corporations are giants in strength and system, but they deteriorate rapidly when deprived of that ability to think which must be supplied to them by individual intellects subject to all the play of human character. The problem is to harmonize individualism and co-operation.

The Everson Myth

On another page we give the salient facts in the life of Mrs. Everson, as recorded in a letter from her son to a committee of the Colorado Scientific Society. Apparently a belated desire had been expressed at Denver to learn something concerning the Carrie J. Everson whose name has been so prominently identified with a famous flotation patent. The melancholy result was to discover that the lady, whose experimental work had been quoted freely in recent litigation, although neither litigant had dared to subpœna her as a witness, had died a year before the enquiry was set afoot. Another consequence is to shatter the romantic story of the alleged invention of the oil-flotation process. It was about time to ascertain the truth. We have been told that Carrie J. Everson of U. S. patent No. 348,157 was a Miss Everson, a school-teacher, the sister of an assayer, in whose laboratory at Denver she had discovered the flotative power of oil by washing some greasy ore-sacks containing concentrate, and that therefrom had resulted the invention of an epoch-making process for treating sulphide ores. Indeed, one authoritative writer gave a final touch to the picture in these words: "When she had the greasy concentrate sacks in the wash-tub and gave them such agitation as was incident to the operation of washing, it only required the customary acuteness of observation of the Western lady school-teacher to grasp the essential facts of sulphide flotation." Alas, our hold on those essential facts is slippery enough even 30 years after the date of the supposed discovery. The excellent lady herself proves to have been a Mrs. Everson, the wife of a Chicago doctor, with no brother assayer and no laboratory for washing ore-sacks or other scientific research. Several years after the patent had been obtained she became a nurse and later still, twenty years subsequent to the filing of that patent, she was for a short time a teacher in a school for girls. The romancist is welcome to that scrap of fact, even if it comes at the wrong place in the story. In short, Mrs. Everson was an intelligent earnest woman who happened to touch the fringe of a metallurgical enigma. We do not ridicule her, nor her effort to investigate a problem that remained entirely unsolved for many long years after she made her amateur experiments; but we permit ourselves a laugh at those who have exaggerated her ineffective attempt into a great invention, in order to belittle the work of real metallurgists and in order to destroy the originality of much later and far more scientific research. The Everson patent describes no workable process; it was forgotten until patent litigation brought it into fictitious prominence. Posthumous demonstrations of the prior art made in court do not impress the detached onlooker. If Mrs. Everson had never recorded her experiments the flotation process would have lost nothing. Flotation was not descended from her. That oil would adhere to metallic particles and float them was known to Herodotus, it has been a matter of encyclopedic information ever since. Mrs. Everson tried to apply the old fact to the concentration of ore, and failed. The flotation of today comes to us through the Elmore brothers, who got their idea from George Robson, at the Glasdir mine, in Wales; where Robson got his idea we do not know, but we hope to find out before the chapter is closed. No reason exists for believing that he got it from the U. S. patent records, for his method bore no resemblance to that of Carrie Everson. From the Elmores the flotation pedigree continues to Alcide Froment, who saw the Elmore bulk-oil process in Italy, and from Froment to H. L. Sulman and H. F. K. Picard. It is only the distortion of scientific vision created by the miasma of litigation that has caused the Everson patent to loom so large against the later investigations and developments of the process. One myth has been swept away; in course of time others may follow it, so that ultimately the scientific truth may stand out clear. Meanwhile we congratulate the Colorado Scientific Society on its course of action and hope that it will not abate in its intention to do honor to a woman who was an investigator, a nurse, a teacher, a good wife, and a devoted mother. That is more than being a bubble in the froth of litigation.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Electrical Theory of Flotation

The Editor:

Sir—I have read with much interest Mr. Bains' article in your issue of the 27th ult. on this subject. I believe he is right in his theory and that electrification plays a very important part in the phenomena of the new metallurgy. The slime problem—the great difficulty mill-men attribute to 'colloids'—is a manifestation of the electrification of the particles causing them to form into flakes and to interfere profoundly with the effect of gravity as utilized in water-concentration methods. I have noticed that dry 'dust' classified by transportation in air is similarly affected and will retain large percentages of air in the mass and will 'run' on a slight grade.

Studying the effect of 'colloids' in gravity work on slime three years ago I noted that some force was causing the extremely fine particles to be attracted to each other with system, and in a manner to suggest that the phenomenon was due to electrification. I assumed, however, that the aluminous and earthy particles were the only ones charged, and that the crystalline sulphide particles which I was trying to separate from the mass were not subject to the queer behavior noted in the 'colloids.' In connection with an application for a patent on a 'colloid separator,' I wrote a description of what was to my mind happening, from which I quote:

By 'slime' is meant, for the purpose of this discussion, a mixture of water with ore and mineral so finely comminuted as to be impalpable. The losses (by gravity concentration) in these sizes are very largely caused by the fact that the slime contains a very large percentage of so-called 'colloids.' In the language of the mill metallurgist, 'colloids' is pulverized ore, affording a great deal of material that contains more than an ordinary amount of combined water, and when in an impalpable state apparently carries a static 'charge' and has the peculiar property of quickly forming into flakes, being then known as 'flocculent slime.'

When greatly diluted with water, that is, when the amount of 'solid' matter in suspension is a very small percentage of the whole and the mass is at the same time in a state of agitation, the formation of flakes is prevented. As the mass of water comes to a state of rest and the solids present begin to fall under the influence of gravity, the crystalloids (more or less cubical particles) go rapidly toward the bottom of the vessel. The colloidal, or clay-making 'solids' also commence to fall, and at the same time begin to migrate toward each other and form themselves into flakes or strings, which behave in water much like fine feathers of fluffy down in air. While the flakes are widely separated the particles of non-electrified, non-hydrous, crystalline material fall readily in paths between them.

When the flakes have settled into a mass touching each other at their extremities, their movement under gravity is interfered with and when in this state they are no longer free-settling particles, but are a mass of flakes resting upon each other with clear water filling their interstices. When they fall farther the mass formation is condensed and the process is one of re-adjustment of the flakes among themselves, in which the water in their interstices is displaced, and on account of the greater degree of impediment as the mass becomes more dense, they require longer periods to fall a given distance or crowd into less space. Thus, each stage of the condensation or thickening process is a successively slower one and one which greatly embarrasses 'gravity' processes of separation.

When I take a long glass cylinder, say of 1½ in. diam., fill it with 100 to 5 slime-feed, as found in average mill conditions (in which all of the mass would pass a 240-mesh screen) and allow the cylinder to stand perpendicularly a short time for the slime to settle and commence the cycle referred to above, I find that by the time approximately 10% of the water is supernatent, that is, clear water on top of slime, then the colloids have migrated under this system of attraction and have become flakes large enough to be seen and have settled until they touch each other. Looking through the glass, I note that the water between the flakes is clear and that the process of re-arrangement among them in process of 'thickening' is visible. The passage of the water upward from among them is made instantly apparent by inclining the tube about 15°. Observing the upper side of the incline I find the water racing along the glass, in the path of least resistance, causing wavelets among the flakes and carrying them upward; and on the under side of the cylinder the movement is downward but in a more uniform manner, that is, a larger section of the mass is moving downward with less speed. When I reverse the inclination of the cylinder the direction of movement is reversed in a surprisingly short interval, with a very short period of rest before starting in the opposite direction. This demonstrates visually the action noted in the re-adjustment of the flakes mentioned, and demonstrates that the water is being squeezed, so to speak, out from

the interstices between the flakes as they rearranged themselves in a more compact mass in the act of falling.

If I take a 'drop' of clean, water-saturated, slimed sulphide which I have previously separated from a similar mixture on a conventional 'slimer' and drop some of it from a glass rod into my cylinder, I can watch the sulphides pass downward through the mass. When the apertures between the flakes are large enough, a majority of the little black crystals are able to reach the bottom, but if I continue this from time to time as the mass thickens I find that the sulphide crystals are being arrested. The finer ones first begin to be held up and may be seen suspended upon the flakes even when the mass looks very thin and extremely fluid-like. By the time the 'colloids' have excluded the water until the proportion in the mass is 100:10, all sizes of the so-called 'slime-sulphide' concentrate are held up on it like coal-dust or sand supported upon down.

When the 'colloids' first begin to settle and combine into flakes they are feathery in appearance in the water, especially toward the surface of 'slime,' but as the mass becomes more dense and less free to move, it assumes a cream-like consistence. When I pour the clear water off from the top and the slime begins to also go over, the appearance by reflected light suggests cream or syrup and viscosity. In very fact I realize that I am dealing with fluid clay.

I think it is entirely obvious that the thickening of slimes in preparation for feeding on so-called 'sliming machines,' as now practised, is entirely wrong in principle. In the absence of the peculiar 'colloids' this would be quite correct and the results upon the machine would be what is intended, but we have the colloids all of the time in all ores (though in varying proportions) and this part of the tonnage is not only *not* amenable to the concentrating action of any machine or device used for water-concentration by the gravity method and cannot be concentrated by these machines, but it prevents the crystalline particles which, when clean of colloids, are easily separated from having a chance to reach the concentrating surface and be saved. We use pointed boxes, spitzkasten, Callow tanks, pulp-thickeners, etc., the object of which is to "thicken the feed," and these devices are admirably adapted to make material so dense that a concentrating unit may handle a larger and more satisfactory *tonnage* of it, but, for reasons that have been explained, the unit will concentrate the valuable portions with very poor success.

Here ends the quotation from my former notes.

Considering what Mr. Bains' experiments and experience have shown I now see that the whole mass of solids was 'charged' and that the effect was misunderstood as far as the coarse particle was concerned, because it was too large to 'migrate' and collect into masses governed by the 'charge,' but as the particles carrying the charge became finer they could migrate and assemble so as to become visible. The sulphide particles were not exempt from the influence as I had supposed. Their suspension in the mass of colloids was not a mechanical proposition altogether or so much as it was one of attraction due to the charge of electricity present in the mass, and the superfine sulphide particle contained in the mass of flakes was just as much an electrically charged colloid as any other part of the mass, and that is where the main losses, the unavoidable losses, were, and where the apparently easy and most notable saving by flotation comes into play.

Now comes flotation with its peculiar and unexplained influence upon the colloid condition, and I am satisfied that the new theory points the way to a better understanding and realization of what is taking place in connection with the burden-carrying bubble. Oil evidently does not belong at the head of the class and has been enjoying a measure of popularity that does not belong to it. Verily, much is yet to be learned about how, and why, and what, is flotation.

I am sending herewith a small sample of Anaconda concentrate which seems to have peculiar properties. It is not a sample of the average concentrate of its size, but is a class of pyrite which selects itself out of the feed in passing over the table and floats off on the surface of the water. Note its relatively coarse size (20-mesh). It is plentiful at times and scarce at other times, evidently depending upon where the ore comes from for that day. It has not been oiled either purposely or by accident, but it will float persistently, as you will note if you put the dry material in a pan and allow a tongue or wedge of water to crawl under it. As soon as it is drained, the film of water will peel off from this material like it does from a duck's back and it advertises that it wants to float by doing so at every opportunity. This material won't stay drowned, and the question naturally arises as to what is peculiar about it and what can be learned by studying its peculiarities. I am sending some of it to Mr. Bains with a copy of this letter.

DAVID COLE.

El Paso, December 14, 1915.

Trade in South America

The Editor:

Sir—Your remarks on this subject are very good. You should enlarge upon it and while doing this, refer to some particular line of trade. It is not possible to say much in general terms without making mistakes.

I take it that your readers are more interested in the machinery trade with South America than with simply 'trade.' And the 'machinery trade' should be again limited to machinery trade other than agricultural. The reason for this is that there is no similarity between agricultural machinery business and mining, power, or nitrate machinery business.

Agricultural machinery is sold by big houses that give a year or two of credit, based on crops, which are in turn often contracted for when machinery purchases are made. This makes it difficult for the American manufacturer of agricultural machinery to retail for cash.

Electrical machinery is usually sold on long terms to

lighting and power companies by the European manufacturer that takes an interest in the business. I should say this *was* the way this business was done. None is being done in this line now.

Mining machinery is sold here, as in other parts of the world, for cash. There are occasional exceptions to this, but the results of giving time on mining sales are not such as to inspire imitation.

In other lines, such as shirts, shoes, and shelf goods in general, longer terms were granted by European houses than by American, but there are two ways of looking at this question of terms. The American manufacturer can either hold out for his terms of cash, or he can give away and allow credits, or he and his customer can compromise. If there was just one American manufacturer, this could be settled easily, but there are many, and American goods are appearing on the market, so the terms finally arranged must be satisfactory to both sides.

Personally, I think that the allowing of a special discount for cash is a better way for the buyer than giving him a long credit and covering it in the price; and apparently the buyer here thinks so also. Anyway, why should it be necessary for the American shipper to change his methods if they are better than the European, as he thinks?

Dollar exchange is appearing in the financial circles with much greater frequency, lately. The Braden and Chuquicamata companies try to obtain all the money required for their operations by selling 90-day New York exchange. So far their arrangements for doing this are not convenient. That is, it is easier for me to go to the bank and buy the exchange on New York than it is to call up the Braden Copper Co. at Rancagua, get a quotation, send them the money, and wait for the draft, even though their rate of exchange is better than that of the bank. It is stated that this condition will be changed, and then we will have an American bank to all intents and purposes, except as regards lending money.

I think you lay too much stress on the importance of speaking Spanish. We have, among the American colony, men who have been here a score of years without learning much about Spanish—and there are Englishmen who could be here centuries without learning the subjunctive any better than I have. Yet the Englishmen do most of the business in Chile. If the men sent to South America to do banking know banking the task of learning enough Spanish is only a question of a short time.

So far, any sales of New York drafts are based on the rate of exchange between pesos and pounds sterling. As soon as we have an exchange rate quoted in dollars, trading in New York exchange will be much easier. Not long ago the first sale of nitrate in dollars was effected in Valparaiso. Not long ago the first sale of tin concentrate was contracted in dollars. A number of locally represented American companies have given instructions that hereafter quotations must be made only in dollars, and not in pounds, pesos, marks, or francs. These are straws that show that the importance of the dollar is increasing.

Occasionally my customers wish to pay accounts with 90-day sterling exchange. Our account will be in dollars at sight in New York, so this means figuring the exchange. In order to be able to remit dollars, I must go to a bank here in Santiago and ask what the rate is. They in turn must ask Valparaiso, because the rate of exchange is based on the sale of drafts at Valparaiso. I return to the bank in the afternoon and they give me a rate. From this I figure the value of a dollar in pounds and get the draft from my customer for the right amount. This draft must be used to purchase between 2 and 4 p.m. of the same day New York exchange, or I am liable to loose or gain by the fluctuation of exchange, because a new rate must be obtained on the next day. You can see what trouble this entails. Another difficulty is that the rate is not the same at all the banks, so that it becomes necessary to ask several in order to know which is the best rate. Their rates depend upon whether they wish to sell or buy on that particular day. So it is that at times I have been asked, "Are you sure going to buy?" before I have been quoted a rate.

My company remits funds for current expenses in drafts on New York, and it is in such cases that I am keen on getting the best possible rate. When the draft is such that any bank will accept it, the difference in price offered is sometimes as much as 2%. Even in cases where the draft is drawn directly on a given bank here, it is possible to obtain a better rate than is originally quoted if one is independent and in a position to send the draft back to New York if the price is not right.

This is not like banking elsewhere, but the condition is not to be charged to the banks so much as to the uncertainty of the value of Chilean money from day to day. Nevertheless, it is to be hoped that if an American bank is ever established here, it will not quote different rates to different people.

MARK R. LAMB.

Santiago, December 4, 1915.

THE WEEDON COPPER MINE in the Eastern Townships of Quebec has produced in five years 174,000 tons of cupriferous pyrite ore. According to a recent report on the 'Copper Deposits of the Eastern Townships of Quebec' by the Provincial Department of Mines, the main orebody of the Weedon is a lense 570 ft. long, 40 to 45 ft. in maximum thickness, striking north-east and dipping 40° to the south-east. The ore averages 3.6% copper, 40.7% sulphur, with traces of zinc, lead, silver, and gold; it has been sold for about $9 per ton. On September 1, 1914, about 200,000 tons of ore was known to be in reserve. The mine is 3½ miles from the railroad to which transportation of the ore is effected by an aerial tramway; the cost of this transportation by tramway is under 7 cents per ton. John McDonald of Sherbrooke, Quebec, bought the property for a small sum in 1908, on account of its rusty showing of schist. He sunk several pits and finally a shaft in the bottom of a grass-covered depression, penetrating 25 ft. of ore. The property was leased under option to P. de P. Ricketts of New York, who transferred it to the East Canada Smelting Co.

Carrie J. Everson and Flotation

The Colorado Scientific Society recently started an inquiry into the work of Carrie Jane Everson, who did some early work in connection with the flotation process in Colorado. The committee of investigation consisted of H. C. Parmelee, the secretary of the Society, Philip Argall and George E. Collins; the last mentioned being chairman of the committee. The chief result was to elicit an authoritative account of Mrs. Everson's life from her son, John L. Everson, of San Anselmo, California. From this account it appears that many of the details circulated in the literature of flotation are quite incorrect.

Her maiden name was Billings. She was born at Sharon, Massachusetts, in 1842, and in 1851, when only nine years old, went with her parents to Illinois, where in 1864 she married William K. Everson, a physician and surgeon practising at Chicago. Through her husband she became interested in chemistry. In 1878 Dr. Everson lost money in one of Brick Pomeroy's wild-cat mining schemes, causing his wife to seek a means of adding to their livelihood. She studied mineralogy and chemistry, and, as her son states, "discovered what she termed the chemical affinity of oils and fatty substances for mineral particles. She later qualified this theory when she learned by further experiments that other substances would accomplish the same results, notably wheat-gluten, lamp-black, soot, etc." Her husband became interested in these experiments and aided her in obtaining the celebrated patent, No. 348,157, of August 29, 1885. Two years later the family moved to Denver, where Dr. Everson tried vainly to get mining men interested in the process. He died in 1889. Thereupon his widow, being in financial straits, took to obstetrical nursing. At this time she met Thomas F. Criley, who tried to get some people at Baker City, Oregon, to interest themselves in the process. Criley died shortly afterward. Then, in 1891, Mrs. Everson met Charles B. Hebron, who had a little knowledge of concentrating plants and arranged to aid her in mechanical details. The joint patent No. 471,174 of 1891, was a result of this association. A Mr. Pischel of Denver is also mentioned by her son as having become interested to the extent of furnishing funds for the erection of a demonstration plant. One or two trials were made in this experimental plant, but a disagreement between Hebron and Pischel caused the abandonment of the scheme and a final cessation of her courageous effort to make something out of her patents. Thereupon, in 1892, Mrs. Everson became visiting nurse of the Denver Flower Mission and was employed in this capacity until 1906, when failing health caused her to accept a position as teacher of physiology and hygiene in the State School for Girls at Morrison, Colorado. In 1909 she joined her son in San Francisco, and later at their joint home at San Anselmo, where she died on November 3, 1914, being then 72 years of age.

Concentrating Molybdenum

As is generally known, molybdenum is in great demand at present as a substitute for tungsten in the making of tool steel. The principal ore, molybdenite (MoS_2) much resembles graphite in appearance, having, however, a little bluer color and giving a green streak on fractured porcelain. Molybdenite occurs commercially in narrow veins in granite and crystalline rocks. The concentration of the ore, containing from 1% to 10 or 20% of MoS_2, to a merchantable product of 80 or 90%, is receiving attention in various parts of this country and Canada. The Canadian Department of Mines, at Ottawa, has been experimenting along these lines, and has lately obtained one of the flotation machines of Henry Wood of Denver for its testing laboratory. Mr. Wood has concentrated molybdenite ores from several localities in the Western states and British Columbia, and claims that his machine will separate molybdenite from gangue without preliminary sizing, yielding a merchantable concentrate, and recovering 80 to 90% of the molybdenite. The Mines Department at Ottawa apparently favors preliminary sizing and in some cases a roasting operation.

According to the *Canadian Mining Journal* the process suggested by the Mines Department as devised from treating 2½% ore containing other sulphides and mica from the Chisholm mine, in Ontario, is as follows:

Crush to inch size. Dry in a cylindrical drier that does not allow the furnace-gases to come in contact with the ore. Pass to ½-in. rolls; thence to a Newago screen that gives material over ¼-in. to a picking-belt, material over ¼-in. going to another picking-belt, and under ⅛-in. to a Keedy sizer. The picking-belts carry the product to ¼-in. rolls, thence it passes over a Newago screen, from which over ¼-in. size goes to ⅛-in. rolls, and under ⅛-in. to a Keedy sizer. All the ore (finally under ⅛-in. size) goes to a Keedy sizer, which is simply a large flour-bolter made exceptionally strong. This makes ten sizes, each of which goes to its own water-flotation machine; the dust passing to an oil-flotation machine or to waste, depending on its content of molybdenum. The tailing from the water-flotation goes to waste. The concentrate, containing 20 to 30% molybdenite, goes to a Wilfley roaster that subjects it to a slightly oxidizing roast at about 1000° F. Careful roasting is necessary to obviate any partial oxidation of molybdenite. The roasted concentrate, now containing oxidized pyrite and pyrrhotite as well as some mica and gangue, is again concentrated by water-flotation machines, giving a product of about 80% molybdenite. The tailing from the roasted ore can be ground and treated in oil-flotation units or can be dried and returned to the Keedy sizer. On the ore tested, 50% of the molybdenite was recovered by crushing in steps and picking out the coarse flake that yields material coarser than 6-mesh.

Prices for molybdenum remain around $1.50 per pound for a product containing 90% MoS_2. Frequent reports are published regarding the discovery of new deposits, and the 1916 output should be of fair quantity.

Theoretical Considerations Governing the Persistence of Ore

By T. A. Rickard

*The non-persistence of ore in depth has disconcerted the miner from time immemorial. The geologist did little to explain the difficulty until the effects of oxygenated water within the vadose zone were elucidated by Posepny, and the water-level became recognized as a factor in the distribution of rich ore. When Emmons[1] and Weed[2] brought forward an explanation for the secondary enrichment of copper lodes, and others, including myself,[3] followed suit with a discussion of the conditions affecting concentrations of gold in veins, then the miner sat up and took notice, as it were, for the geologist began to touch upon the one subject most important to him, namely, the ascertainment of the factors favoring the making of those extraordinary concentrations of metal for which he has sought since first a pick struck the earth. The miner does not seek merely for gold in quartz, galena in limestone, or cinnabar in serpentine, for example; he seeks for those few spots where the gold, the lead, or the mercury is in a form or in a mass so concentrated as to yield him a handsome profit. Mining is the art of exploiting enrichments, not universal disseminations. There is gold in seawater, what profits that?

So when theories of secondary enrichment, with all the deductions arising therefrom, began to made headway, they, being true, prevailed over the old generalization, being untrue. One of the first systematic statements on the subject was tendered, most fitly, by that keen observer and effective teacher, Waldemar Lindgren, in 1905. In the first volume of *Economic Geology*[4] he wrote an article entitled 'Ore Deposition and Deep Mining.' That article summarizes current theory on the subject we are discussing. Turning to what Mr. Lindgren has to say concerning "deposits in which the metal is of later origin than the surrounding rock," we find that he considers contact-metamorphic deposits to be non-persistent. "Slight changes of composition and texture of the rock influence their susceptibility to contact metamorphism to a very surprising degree. Few mines on contact deposits have been worked at a greater depth than a few hundred feet."

Concerning the deposits "in which the ores have

[4]Vol. 1, pp. 34-36, October-November, 1905.

been deposited either by filling or replacement along fissures or other paths for underground waters," he states that the views now generally accepted agree in supposing the metallic contents to have been "deposited by ascending hot solutions—in fact, ascending hot springs—and most observers also agree that the metals were taken up in solution by the water at some point considerably below the point of precipitation." He allows that "the conditions for deposition grow less favorable as depth increases, but the change takes place slowly. The richest ores are those near to their original apex." Here he is referring to the erosion of the upper portion of the vein as originally formed. Finally, he concludes, on theoretical grounds, that "ores deposited by ascending hot waters are more likely to show a decrease than an increase in value when developed by deep mining."

However, this is not all that he has to say. It is important to note his suggestion that in some cases erosion may have removed so much of the vein or lode that the present outcrop "may be thousands of feet below the point where the fissure reached the surface during the vein-forming epoch." Applying this idea, he distinguishes between veins traversing volcanic rocks of relatively recent geological age and those penetrating older intrusive rocks known to have consolidated at great depth. He argues therefrom that "the date of vein formation" in the latter case "is likely to be remote," as compared with the former. He places the veins of the Southern Appalachian region, of the California gold belt, and of Australia under the first category, while he mentions the mining districts of western Nevada, the Hauraki peninsula in New Zealand, Owyhee county in Idaho, the San Juan region and the Cripple Creek district, both in Colorado, as in the younger class of deposits. Mr. Lindgren argues, for example, that because "the thickness of crust removed by erosion in the foot-hill region" of California is 3000 ft., and the most persistent orebody as yet discovered has been mined to 3000 ft. vertically, therefore "deposition of free gold ores in the California veins has proceeded to depths from the surface of about 6000 feet."

This argument assumes that the ore as now found is much the same in character and richness as it was at the time when the vein was first formed: it infers the geological age of the orebody from that of the vein in which it lies. To this I demur. The vein, of course, cannot be older than the rock by which it is encased, but it may be much younger: moreover, the ore as now found by the miner in the vein may be considerably younger than the fissure or other receptacle in which it lies. Furthermore, I am discussing the vertical distribution of enrichments, not of the mere vein-filling, for the orebodies exploited by man represent the selected parts of a lode, not the whole of it, and certainly not its poorer portions. I submit that these rich parts may be the result of later chemical reactions long post-dating the waters that first circulated along the fissure and precipitated the primary ore. In short, I submit that most orebodies that is, the rich parts of a lode, are geologically young.

The suggestion made by Mr. Lindgren, that the present veins may be only the stumps, as it were, of those that at one time, previous to erosion, reached to a former surface several thousand feet higher than their present outcrops, has been advocated with some enthusiasm by persons of less acknowledged authority in matters of this kind. A good example is afforded by the literature on the goldfields of Nova Scotia. In that Canadian province the small veins of gold-bearing quartz follow thin beds of slate belonging to an extensive series of slates and sandstones of pre-Cambrian age. This sedimentary formation has not only been metamorphosed, but it has also been subjected to violent plication resulting in sharp anticlinal folds, so that the quartz veins assume the shape of saddles, which by the further action of cross-folds, become domes.[5] Apart from these structural features, it is a remarkable fact that this sedimentary formation has a known thickness of 30,000 ft., of which 18,000 ft. constitutes the division characterized by gold veins. It is estimated by E. R. Faribault, J. E. Woodman, and other geologists who have studied the series, that erosion has removed overlying rock several miles thick. Mr. Faribault writes[6] of the veins having been "truncated by extensive denudation." Again he says: "Some of the sharpest and highest folds have been truncated to a depth, as far as we know, of over eight miles, exposing at the surface a section of gold-measures of over five miles in thickness." This means that 8 miles has been denuded, and that the gold veins persist through the underlying and surviving 5 miles of rock. His diagrams express the same idea. Several less-known writers on the geology of the Nova Scotian goldfields have argued likewise: that the little quartz veins to be seen nowadays at the surface are the stumps of veins that once reached three or four miles to the surface of a former period, and therefore, that these same little veins may persist a few miles deeper, thus arriving at the cheerful conclusion that gold mining in Nova Scotia is "in its infancy."

This reminds me of the cynic's definition of faith as believing things you know to be untrue. It is a brutal fact that of the gold veins that are supposed, on a geological diagram, to have continued several miles overhead and to persist yet for several miles underfoot, not one has been exploited profitably to a vertical depth of more than 1100 ft.[7] Most of the little mines in Nova

[5] 'The Domes of Nova Scotia.' By T. A. Rickard. *Trans. Inst. M. M.*, Vol. XXI, pp. 506-566.

[6] 'The Gold Measures of Nova Scotia and Deep Mining.' By E. R. Faribault. *Mining Society of Nova Scotia*, 1899.

[7] The deepest gold mine in Nova Scotia is the Libbey property at Brookfield, Queen's county. This was worked to a vertical depth of 1062 ft., following the orebody on its pitch by means of an incline. The Lake lode, at Caribou, in Halifax county, was mined to a vertical depth of 1000 ft. Not more than a couple of dozen mines were exploited to a depth greater than 500 ft. vertical.

Scotia that have given good results were abandoned when they were 200 to 300 ft. deep. When a man tells me that a 6-inch quartz vein once penetrated rock, now eroded, for several miles, either way, up and down, from the spot where I now see it, I marvel at his imagination; and when I find that a prospect-hole, or at most a shaft only a couple of hundred feet deep, suffices to follow that vein to its vanishing point, I turn to him and say to him that he has stated something that is scientifically untrue.

Even if the actual story of mining in Nova Scotia had not given the laugh to any such assumption of persistence on quasi-geological grounds, we should be warranted in rejecting the theory of continuity on such knowledge as is extant concerning the origin of ore deposits in general. Mr. Faribault and others assume that the granite, of Silurian age, was extruded after the gold veins had been formed, "for granite dikes and veins have been observed to always cut the inter-stratified quartz veins wherever they come in contact with them." This is open to doubt. At Forest Hill the quartz of a vein can be seen penetrating into the granite, and gold is visible both in this quartz and in that of a vein near-by.[8] Mineralization is usually the sequel to eruptive activity. In Colorado, almost without exception, the deposition of ore over a wide region of great geological diversity is known to have taken place in post-Cretaceous time, and in most cases it can be proved that the orebodies hitherto discovered were formed after the extraordinary eruptive activity of the early Tertiary period.[9] I could quote scores of other examples indicating the geological recency of the agencies that may be connected justifiably with the deposition of ore, not of the precious metals only, but of the base ones as well. Even if the evidence indicates that a vein was formed at an early date in geological history, before erosion had removed thousands of feet of younger rock, it still remains to be proved that the metals enriching that particular vein were precipitated at so early a period where we now find them; and even then it is incumbent on those who argue persistence of ore on the basis of the geologic antiquity of the veins, to prove that the richest portions, namely, the orebodies, were not the product of activities belonging to a much later time. We are entitled to make this last stipulation, because, as I have said, and have elsewhere proved, so many orebodies are definitely known to be the products of the thermal and igneous activities that came into play at a period long subsequent to that in which the veins themselves were

first formed. Let me quote the case of the Homestake.

That celebrated lode, in South Dakota, consists of a mineralized zone in schist, known to be of pre-Cambrian age. In the overlying Cambrian conglomerate are found boulders recognizable as eroded fragments of the lode schist. The conglomerate is a 'banket' deposit, for it contains enough gold to be exploited as ore. So here, it has been said, we have proof of a gold-bearing lode of pre-Cambrian age, for is not the débris of it and the gold of it found as a constituent of a Cambrian conglomerate?

As early as 1882 W. B. Devereux indicated that part of the gold in the overlying Potsdam conglomerate was not of mechanical origin, derived from the erosion of the Homestake outcrop, but had been deposited as a chemical precipitate, for he found it as a film between the folia of the schist and in the overlying quartzite.[10] In 1889, F. R. Carpenter, long resident in the locality as a mine manager, testified that the vicinity of intrusive rock is favorable to the richness of the ore; he concluded that 'porphyry' produced "either an enrichment of the deposit or a further concentration of what gold originally existed in it." In the neighboring district he ascertained that the silver-bearing galena ores, in Cambrian quartzite, are found "only in connection with the igneous intrusions." In the overlying Carboniferous limestone, ore of similar character is found "adjoining the porphyry, where it cuts through the limestone." He then expressed the opinion that the ore-bearing rocks of the region are "co-extensive with the intruded igneous rocks."[11] In 1897, F. C. Smith[12] stated that neither the Potsdam quartzites "nor those of the Carboniferous are ever sufficiently mineralized with the precious metals to be called ores, except in certain localities where they are cut by dikes, covered by flows, or interealated with sheets of igneous rocks."

In 1896 I had an opportunity of going underground in the Homestake mine and of visiting neighboring workings; in 1899 I examined the Hawkeye-Pluma mine, which is in the gold-bearing conglomerate overlying the Homestake lode. I formed an opinion then that the richer portions—that is, the orebodies—of the Homestake schist are associated with the dikes of rhyolite that penetrate not only the overlying Cambrian strata but transgress a formation of shale belonging to a period so late as the Cretaceous. In other words, it seemed likely that the enrichment of the lode was consequent upon thermal action of post-Cretaceous age.

In 1903, J. D. Irving published a paper on the subject.[13] He stated that the fact of the Homestake lode being "mineralized and gold-bearing" in Cambrian time "is proved by the presence of gold in the basal or lowest rocks of the sedimentary series which lie in the isolated patches about the outcrop of the orebody." However, Mr. Irving also says, in regard to the Homestake lode: "It appears, first, that there have been several different periods of mineralization, at least one of which has preceded the deposition of the Cambrian rocks, as is distinctly shown by the presence of placer gold in the lowermost gravel beds of the Cambrian series; second, that there have been periods of mineralization which followed the entire deposition of the sedimentary rocks and were later than the intrusion of the dikes and bodies of rhyolite. It is probable that this belt has been the seat of much fracturing and crushing from very early geological time until the present, constituting a line of weakness along which mineralizing waters were permitted to circulate more freely elsewhere."

In 1904, J. D. Irving, S. F. Emmons, and T. A. Jaggar published a paper on the economic geology of the district.[14] They concluded that while some of the gold in the Potsdam conglomerate is detrital, the high-grade portions of it are indebted to secondary enrichment. This enrichment was contemporaneous with the introduction of the pyrite, which was not an original constituent of the pebbles, but serves now to distinguish the rich parts of the deposit. The pyrite occupies fissures and cavities in the pebbles. Barren conglomerate is cemented by quartzite or by calcite free from pyrite. He refers to the films of gold in the schist.

It is noteworthy that Irving considers the increase from a grade of 1 dwt. gold to the higher average of 10 dwt. per ton to be due to secondary enrichment. In other words, the formation of that part of the deposit that has an economic value—and is therefore 'ore'—is ascribed to the later processes whereby the original detrital deposit was enriched by secondary precipitation. In short, the Cambrian conglomerate became an orebody by reason of chemical precipitation associated with post-Cretaceous, or Tertiary, thermal circulation.

In regard to the Homestake lode, Emmons ascertained that intrusive bodies of rhyolite, of Eocene age, dip and strike with the orebodies, through which they also pass. The breccia formed along their contact with the schist is gold-bearing and pyritic, showing that the "mineralizing solutions must have entered along the channels produced by these movements," which, be it noted, took place in the Eocene period. Thus the gold-bearing ore of the Homestake, once supposed to be wholly of pre-Cambrian age, proves to be largely of Tertiary age; in other words, the enrichment or concentration that changed a zone of crushing into an orebody was not ancient, but young, geologically.

An interesting example of ore deposits undoubtedly due to more than one period of formation is afforded by the copper veins of Butte, in which chalcocite has orig-

inated[15] in at least three ways, and at three different periods:

(1) As a primary deposit from ascending solutions;

(2) As a secondary deposit from ascending solutions; and

(3) As a secondary deposit from descending solutions.

Indeed, the idea that ore deposits as now found came into being at one moment of geological time and have survived unaltered through the continual interplay of natural forces, operating for periods during which the Alps and Andes might come and go like a child's sand-castles before the encroaching tide, is contrary to all the teachings of geology. On the contrary, the evidence, especially that gathered during recent years in connection with secondary enrichment, all goes to show that the orebodies found by man today represent the temporary balance between solution and precipitation, between dissemination and concentration. Man, by removing the ore and subjecting it to his own processes, interrupts the work of Nature, who otherwise would continue to modify her handiwork indefinitely. The idea of fixity in the composition of an orebody is as

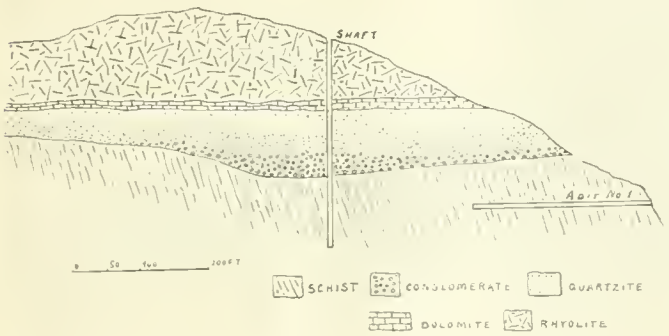

FIG. 3.

THE GOLD-BEARING CONGLOMERATE IN THE HAWKEYE-PLUMA MINE.

After J. D. Irving.

repellant geologically as the notion that the present face of the earth is permanent.

Among those that have demurred to the conclusion I am seeking to establish is J. Malcolm Maclaren. Two years ago, in discussion of a couple of articles[16] on this subject written by me, he objected[17] to one generalization being replaced by another; that is, while he could not support the old idea of general persistence, he considered my sweeping contradiction to be a "pernicious doctrine, if universally applied." He makes a big exception for ore deposits in Archean and Paleozoic rocks, and even several in Mesozoic rocks. Imputing the ore-bearing character of such lodes to a favorable country-rock, he concludes that the richness will continue downward until the lode passes out of the favorable rock. He instances the Mother lode in California, the Treadwell lode in Alaska, and the Champion vein in India to support his conclusion. He endeavors to make a point of differentiating between geologic structure and depth *per se*.

Having regard to Dr. Maclaren's knowledge of economic geology, this may be considered the best argument yet advanced in favor of an idea that I consider ripe for final sepulture. The argument is ingenious, but it amounts only to a red herring across the trail we are trying to follow. Suppose we accept geologic structure as more decisive than depth, does that falsify the argument from world-wide experience? Of course not. Increase of depth involves change of geologic structure. It is most unlikely that a mine opening can be extended downward for many thousand feet without exposing a change of rock or of rock-structure. The probability of change is implicit in the idea of depth.

He refers to the Champion lode, in the Kolar goldfield, and says that "if it should fail at greater depths, it will fail not on account of the depth, but because the fissure has passed from hornblende-schist into the gran-

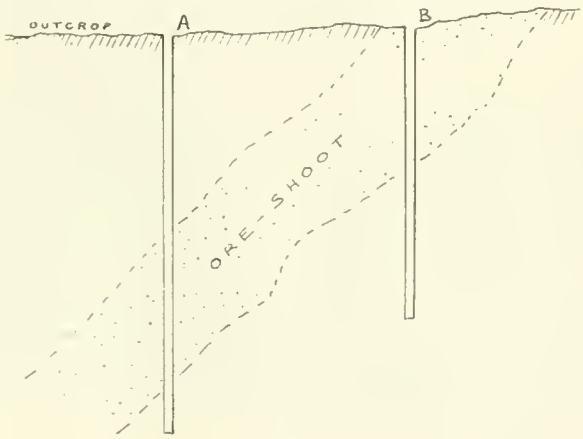

FIG. 4.

ite, and so far as I [Dr. Maclaren] know, there is no evidence to indicate such a change is likely to take place." To this I reply that the Champion lode, without marked change of geologic encasement, has become impoverished in depth.

That impoverishment or even abrupt cessation of ore may ensue from a change in the structure or composition of the wall-rocks is true, of course. This is an explanation, not a rebuttal, of my argument. We are all aware that ore-shoots have a pitch that takes them beyond one line of vertical descent and may bring them across another line of descent, as is illustrated in Fig. 4, where shaft *B* is started in the ore-shoot and goes out of it in depth. On the other hand shaft *A* starts in a barren portion of the lode and does not strike ore until a depth of several hundred feet has been gained. It would be as illogical to conclude, from *B*, that the ore peters out at, say, 300 ft., as it would be to assume, from *A*, that enrichment with depth has been proved at 350 ft. At Oatman, Arizona, at the present time, we have more than one illustration of the conditions typified by shaft *A*; it is highly probable that the explanation will be similar in kind. One reason for missing the outcrop of an orebody and starting to prospect in a relatively poor

[15] Austin F. Rogers. *Economic Geology*, Vol. VIII, No. 8, p. 794.

[16] 'Persistence of Ore in Depth,' *Mining and Scientific Press*, August 24 and 31, 1912.

[17] *Mining and Scientific Press*, October 26, 1912.

portion of the vein is the fact that where the ore is soft or easily decomposed, the ore shoot exhibits no outcrop, on the contrary, it is covered with a mantle of detritus sufficiently thick to cause the prospector to miss it.

We miners are also aware that a 'congenial' rock exercises an important influence on the distribution of ore. Cornishmen have known that since the days when the Phoenicians came to the Cassiterides. In Fig. 5 a group

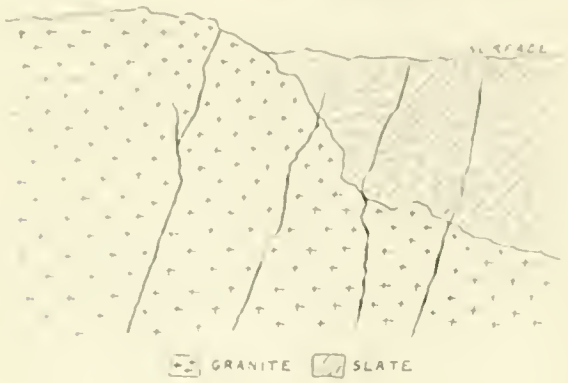

Fig. 5.

of veins is shown passing from slate into granite. Under such conditions no ore may be found in the veins until they penetrate the granite, or else they carry copper when in the slate and tin when in the granite, as has been the case at Dolcoath and other Cornish mines. Another good example of a congenial rock is illustrated by Fig. 6, where a vein, itself of minor consequence as an ore-carrier, is capped by a rich mass of ore in a bed of dolomite. Such conditions exist in the Black Hills of South Dakota. The flat orebodies of Newman hill, at Rico, Colorado, also belong to this type, only there the

Fig. 6.

favorable horizon is marked by a bed of gypsum. In both cases, however, the roof or upper limit of enrichment is shale, which appears to have been relatively impervious to the mineralizing waters that impregnated the soluble dolomite and gypsum. Here also the miner was compelled, in most cases, to sink several hundred feet, or to drive a long adit into a hill, in order to reach the place of enrichment, yet when he followed the veins that had fed the so-called contacts he found that they became impoverished at a short distance below the ore-bearing horizon.

Another type of contact is shown in Fig. 7, where a porphyrite adjoins a limestone. Such igneous contacts with soluble rocks have proved good places for the finding of ores, both those of lead and of copper, as at Leadville and at Clifton. The neighborhood of dikes and intercalations of irruptive rock has proved favorable in the search for gold and silver also, in numberless localities all over the world.

Finally, I may instance the crossing of veins as a structural condition appreciated by the miner as a place likely to be marked by an enrichment. See Fig. 8.

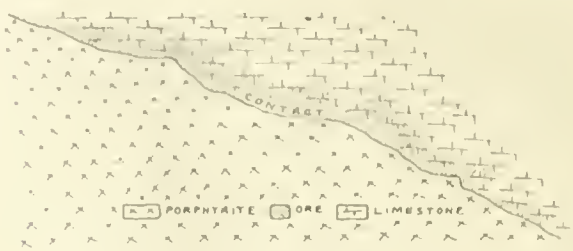

Fig. 7.

Other examples of the localization of ore by reason of structural relationships might be cited, but those given will suffice. Such favorable conditions may recur in depth, and they are found at varying distances from the surface, but the effect of them in promoting the deposition of ore becomes modified in depth by the increase of temperature and of pressure. Moreover, the tightening of the ground, as the miner phrases it, tends to decrease the multiplicity and continuity of fracturing, thereby impeding the circulation of mineralizing waters and

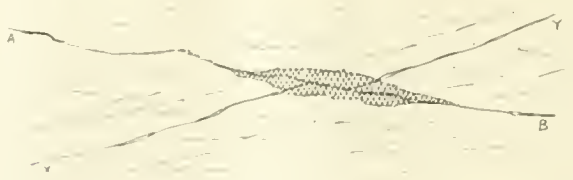

Fig. 8.

checking those exchanges and reactions between solutions of diverse composition to which the precipitation of ore is largely due.

Manganese ore from the Caucasian region of Russia was produced to the amount of 730,310 short tons in 1914, which is 338,415 tons less than in 1913. Practically all of the annual production is customarily exported; before the War, Germany and Belgium were the best customers, while Great Britain, United States, Austria, and France took smaller quantities.

White arsenic production of the United States in 1915 was 5195 tons, worth at the smelters 2c. per pound, or a total of $207,780. This is 11% over 1914, and 65% over 1913.

Mining Districts of Northern Ontario

By Robert Livermore

†THE mining districts of the Province of Ontario may be divided into two classes: the precious-metal, gold and silver, producing areas; and the other mineral-producing districts, such as copper, nickel, iron, and the commercial earths. At present productive mines of the former class belong to the northern part,

WINTER PROSPECTING.

and of the latter to the southern part of the Province. This, however, is a general statement only, as deposits of the precious metals have been known and worked for many years in the older southern districts, while considerable deposits of the baser metals are known, and at least one profitable deposit of nickel is being worked in the north. Still, the division is correct for the purpose of this article, which is to describe in general terms the gold and silver districts, and the conditions of mining in them.

The precious-metal mining districts may again be divided into two distinct groups: gold and silver; for unlike most of the Western mining districts, there is a very clear line of demarcation between the two, since gold rarely occurs in any considerable quantity with the silver ores, while silver, although found to some extent in the gold-bearing veins, is a by-product only. The chief reason for this is to be found in the fact that the veins of the two groups, though all in rocks of pre-Cambrian age, were formed under different geological and chemical conditions, and at different periods.

The silver deposits are all in, or associated with, the rocks now named from the district which contains the most important deposits, the Cobalt Series. This series is of Huronian age, with later intrusions of diabase, and overlies unconformably a base of complex rock consisting of greenstones, altered slates and porphyries of the Keewatin age. The Keewatin rocks are not properly of the series, but important silver veins existing in this formation were affected by the same geological conditions as those responsible for

THE CONIAGAS MINE.

the deposition of the silver ores in the Huronian. The Cobalt series proper consists mainly of slate, pebble conglomerate, and graywacke. It was originally deposited by sedimentary action on the uneven Keewatin floor, and subsequently tilted, faulted, and eroded, so that its thickness varies greatly, and its former horizontal bedding-planes are rarely maintained in that position. Its sedi-

sedimentary character is clearly shown in the waterworn pebbles of the conglomerate and the even stratification of the slate.

Subsequent to the laying down of the Huronian measures there was a great intrusion or eruption of diabase, which in the form of a huge sheet or sill cut through or spread over the entire series as well as the underlying Keewatin. This sill has been proved to be over 500 ft. thick. The generally accepted theory is that the shattering and fissuring of the rock that opened the way for the ore-bearing veins took place by contraction when this eruptive cooled, and that the diabase itself was the source of the silver. Some engineers of repute hold that the fissuring was subsequent to the eruptive flow, and not directly due to it, and that the silver was deposited from deep-seated solutions, in one or the other formation according to the favorable chemical conditions of the wall rocks. Faults are quite numerous, varying from mere steps in the bedding-planes to throws of many feet. These seem in some cases to have influenced the deposition of the ore in the veins, notably in the vicinity of the great fault under Cobalt lake, and in the South Lorain district, where the orebodies have usually been found near the faulted contact between the diabase and the Keewatin. The faults themselves, however, rarely form ore-zones.

The veins occur in all three formations: the basal Keewatin, the more recent Huronian, and the intrusive diabase. They are far more numerous in the Huronian than in the other formations, so much so that it has been the custom to measure the probable life of the district by the known areas of Huronian rocks. That this is not entirely the case is shown by the fact that important deposits in both diabase and Keewatin, which have added largely to the total production, have been worked since the early days of the district, and discoveries are still being made in these formations. In fact, since the Huronian terrain is distinctly limited both in area and depth, the best hopes for the future lie in exploration of these deeper-seated rocks.

In general it may be said that the veins occurring in the Huronian are far more dependable than those in other formations, and one fact is universally recognized, that a vein which carries ore in one of the three principal rock-series named, will carry it in that series alone, and though the vein itself may continue in strength for some distance, it will rarely contain ore for more than a few feet in a different series.

The silver occurs in several forms; native silver, in sheets, masses, and in fine combination with other minerals being the most common form. Proustite, argentite, and dyserasite are also common. Closely associated with the silver are the cobalt compounds, smaltite and cobaltite. It is from this mineral that the camp takes its name, as the prominent outcroppings of cobalt bloom attracted the first notice to the veins. Niccolite is nearly as common as smaltite, and is usually an ore-bearing mineral. The commoner minerals, galena, pyrite, and chalcopyrite are frequent in occurrence, but are never good indications of ore. The vein-filling is almost invariably calcite and dolomite. Where quartz occurs it is a sign that no silver will be found.

In conjunction with the vein there is usually an impregnation of the wall rocks with silver, extending from a few inches to widths of many feet from the veins. In the early days little attention was paid to this feature, both for lack of methods for treatment, and because the high grade ore was so easily won; but with the approaching exhaustion of the high-grade, the low grade mill ore has become of increasing importance, and today a very large tonnage is treated in the modern plants that have been erected as conditions warranted.

Erosion has played an important part in the physical features of the country, due to the intense glacial action of past ages. Unfortunately for the miner it has not worked entirely to his advantage, for undoubtedly enormous thicknesses of ore-bearing rock have been eliminated. Still, it has not been all one-sided, for just as probably, ore-formations formerly capped or concealed by barren rock have been exposed to view by this agency.

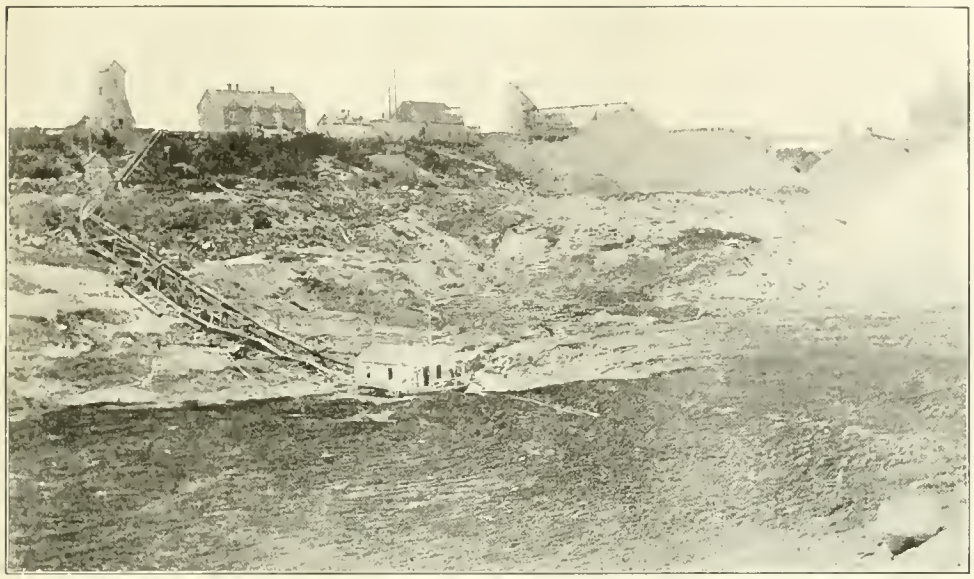
The physical aspect of the Cobalt country is one of low, rounded, rocky hills, rarely exceeding 200 ft. in height, formerly forest-clad, but now unsightly with stumps and brush. Numerous lakes make up a large part of the surface area, and often overlie parts of the mines. The altitude is about 1000 ft., and the climate dry and bracing. The winters are long and cold.

The Cobalt silver district so far overshadows the other silver-producing areas of Ontario that a description of its main features covers the whole subject. The Cobalt district proper includes an area some five miles long by two wide. While other productive localities, such as the Casey-Cobalt mine on the north and the South Lorrain district on the south, extend its limits for over twenty miles, the mines of both the last-mentioned places are simply isolated cases of ore deposition, to which the same features apply as to the parent district.

The district is served by the Temiskaming & Northern Ontario Railway, a government line that gives excellent service to the whole North country. This road, in fact, is the prime reason for the discovery of Cobalt. It was originally projected by the Ontario government to open up for settlement the fertile clay-lands known to lie to the north and west of lake Temiskaming, reaching far north over the height-of-land toward Hudson's Bay. The first ore was found on the shores of Cobalt lake, then known as Long lake, in 1903, by employees of the railway. Not until 1904 was the importance of the deposits recognized, but when it was, a rush set in, and scenes of excitement and 'wild-catting' usual to new finds prevailed. A strange combination of remoteness and accessibility was this rich silver camp in the heart of the northern wilderness, separated by many miles of untracked forest, yet to be reached in one night from the great city of Toronto by comfortable Pullman car. Today, only ten years after the time when none but the timber cruiser, the Indian, or trapper traversed the wilds by canoe and portage, a town of thousands of people, with good buildings of brick and stone, with electric cars and automobiles passing along its streets, stands on the site of the

old forest. So swift is the progress of a prosperous mining community.

Cobalt has produeed in the ten years of its existence more than 210,000,000 ounces of silver, and has paid over $60,000,000 in dividends. For the last five years the production has been maintained at nearly 30,000,000 oz. annually, and although there are signs that this yield is decreasing, the output is still maintained at not far from its high mark. There are at the present time no less than 16 producing and dividend-paying mines in an area five miles long. In normal times there are 5000 men employed in and around the mines, and probably 10,000 people in the district and neighboring towns are dependent directly or indireetly upon the industry.



THE DRAINED BASIN OF KERR LAKE.

There are three main groups of mines: those near and surrounding Cobalt lake, where the town stands and where the first discoveries were made; those in the Kerr Lake district two and a half miles south; and those two miles farther south near the granite contact, known as the Temiskaming Beaver mines.

THE TEMISKAMING MINE.

Of these, the first now derives its ore almost entirely from the Huronian formation, and is by far the largest in number of mines and productive area; the second takes a large production from the Huronian, but also has had veins of great richness in both diabase and Keewatin rocks; the third, and smallest, has depended upon the Keewatin for its production until recently.

The Cobalt veins are narrow, rarely exceeding a foot in width, and are irregular in all dimensions. They are, however, extremely rich, probably the richest silver veins ever uncovered. It is not unusual for carload shipments to contain four, five, or six thousand ounces per ton. The characteristics of the veins make it exceedingly hard to estimate their future productivity. This uncertainty has hurt many of the properties from an investment point of view, and economically speaking, has operated against initial installment of efficient equipment, and use of long-sighted mining methods proper to mines of more assured future. In the course of years, greater familiarity with the 'habits' of the ore has enabled engineers to make much more comprehensive estimates of the reserves, so that with the confidence of experience, many of the early mistakes have been set right, and mining and treatment methods brought thoroughly up to date.

The mining practice of Cobalt is not complicated. The wall-rocks are solid and on the whole little timbering is required. The ground is easily broken; and the ore is hoisted to the surfaee for sorting, where the high-grade is picked on belts or bumping-tables, the fine jigged for smaller pieces of high-grade, and the reject sent to the mills. About the only engineering difficulties underground have been those where the valuable deposits lay under water, necessitating greater care in stoping and supporting the ground. At Kerr lake, a body of water some 40 acres in area, and 100 ft. deep had to be considered. The managements of the two companies, parts of whose property lay under it, undertook to drain the lake by mounting powerful pumps

on a scow, and pumping the 400,000,000 gallons of mud and water it was estimated to contain, out of the basin. This has been accomplished, and has thrown the formerly submerged territory open to prospecting and mining. The management of the Cobalt Lake mine, which lies under the lake of the same name, has installed apparatus of similar nature and has commenced draining that lake also.

Surface prospecting has always been a necessary part of the operations, since so many small rich veins lie irregularly over it, which would be difficult and expensive to find underground. This has usually been done by trenching through the drift material, but the Nipissing Mining Co., which has a large surface area, has tried the interesting and successful experiment of installing a powerful hydraulic plant, which strips large surfaces bare of overburden at a minimum of expense.

Cobalt is not a 'deep' district. Two hundred feet is considered a satisfactory thickness for the Huronian rocks, and the average is still less. The great number of veins and their richness have, however, compensated for the lack of depth, since if ore is concentrated by nature on the surface it is that much more easily mined than lower-grade ores that must be hoisted from greater depth at greater expense in equipment and elaboration of mining methods. This fact is too apt to be overlooked by the investor or engineer, who has always had impressed upon him the desirability of persistence in depth, and the reputation of Cobalt has in the past suffered accordingly. The continued productiveness of the district, however, has gone far toward re-establishing the confidence lost when its shallowness was first recognized. Naturally, depth of ore deposits is highly desirable, for lateral extension of the veins is obviously limited, and in the long run the continuity of industry depends upon the depth to which the ore will go. Signs are not lacking that this factor has still to be determined, as ore has been discovered and mined at quite respectable depths in the Keewatin and diabase. Up to the present, however, all discoveries are well within the 1000-ft. mark.

Almost all of the mining companies treat their low-grade ore in either their own or custom mills. The milling practice varies between simple amalgamation with concentration, and straight cyanidation. The concentrating advocates claim that though a less extraction is made, the loss is offset by the smaller cost of treatment. Those who uphold cyanidation alone say that the higher extraction far more than balances the extra cost. With the operation of the 240-ton low-grade mill of the Nipissing Mining Co., which does away with concentration entirely, and depends upon fine grinding with direct cyanidation, the latter practice has become generally recognized to be the best, and most of the mills are now using cyanide in their scheme of treatment.

Most of the mines have their own steam-driven power-plants, but these are used simply for heating or for auxiliary supply during occasional shortages due to vicissitudes of climate. The main supply is bought from a company that controls the huge water-power on the Montreal and Matabitchouan rivers, and furnishes both electric and compressed air power to the whole district.

Labor, on the whole, is efficient, and of a good class. The rank and file of the men are of all nationalities, with the native-born in the majority. The Nova Scotian gold miners were at first the only experienced machine-men, but of late their places have been filled partly by foreign-born who have proved themselves adept. Finns and Austrian Poles are strong in numbers, and much to the credit of the Canadian temper, the latter have been permitted to continue at work without molestation, in spite of their nationality. Wages, in comparison with Western, and with other camps of Northern Ontario, are not high, ranging from $2.25 to $3.25 per day, but conditions of living are easy and working hours are not long.

Smelting in Australia

As a result of the War, the Broken Hill Associated Smelters Proprietary Co. was formed by three companies operating at Broken Hill to acquire the Broken Hill Proprietary Co.'s plant at Port Pirie, South Australia, connected by rail with the mines and mills, a distance of 250 miles. The weekly capacity of four Ropp roasting-furnaces, seven Dwight-Lloyd sintering machines, 16 Huntington-Heberlein converters, and four blast-furnaces with mechanical feeders, was 3200 tons of 60% lead concentrate per week, and the lead refinery 2000 tons of bullion per week. The zinc smelter works consisted of one Matthieson-Hegeler roasting-furnace and 10 zinc-distillation furnaces, with a total capacity of 350 tons of zinc concentrate, and an output of 100 tons of spelter and blue powder per week. The output is to be increased to 5000 tons of lead concentrate per week, at a cost of about $500,000. The area of the property is 136 acres, also a wharf 1200 ft. long. There are coke-works at Belambi, New South Wales, with a weekly output of 1100 tons for the smelter. The companies at present sending their products to the works are the Proprietary, North, South, and Zinc Corporation. When extensions are completed, the number of contributors will be increased. During the four weeks ended September 22 the following work was reported: concentrate smelted, 11,847 tons; slime smelted, 1210 tons; and silicious ores, 3000 tons, a total of 16,057 tons; refinery products consisted of 6975 tons lead, 59 tons antimonial lead, 296,023 oz. silver, and 372 tons spelter.

At the Pan-American financial congress, held in Washington in May 1915, the following measures were advocated: two-cent letter postage between Latin-American countries and the United States; the adoption of the gold standard in all Latin-American countries; increase and simplification of banking and exchange facilities between the United States and Latin-America; more and faster steamer service; extension of the parcel-post service; better understanding as to tariffs, taxes on shipping, and free zones; publication of commercial laws in English, Spanish, and Portuguese; protection of foreign patents and trade-marks in South America.

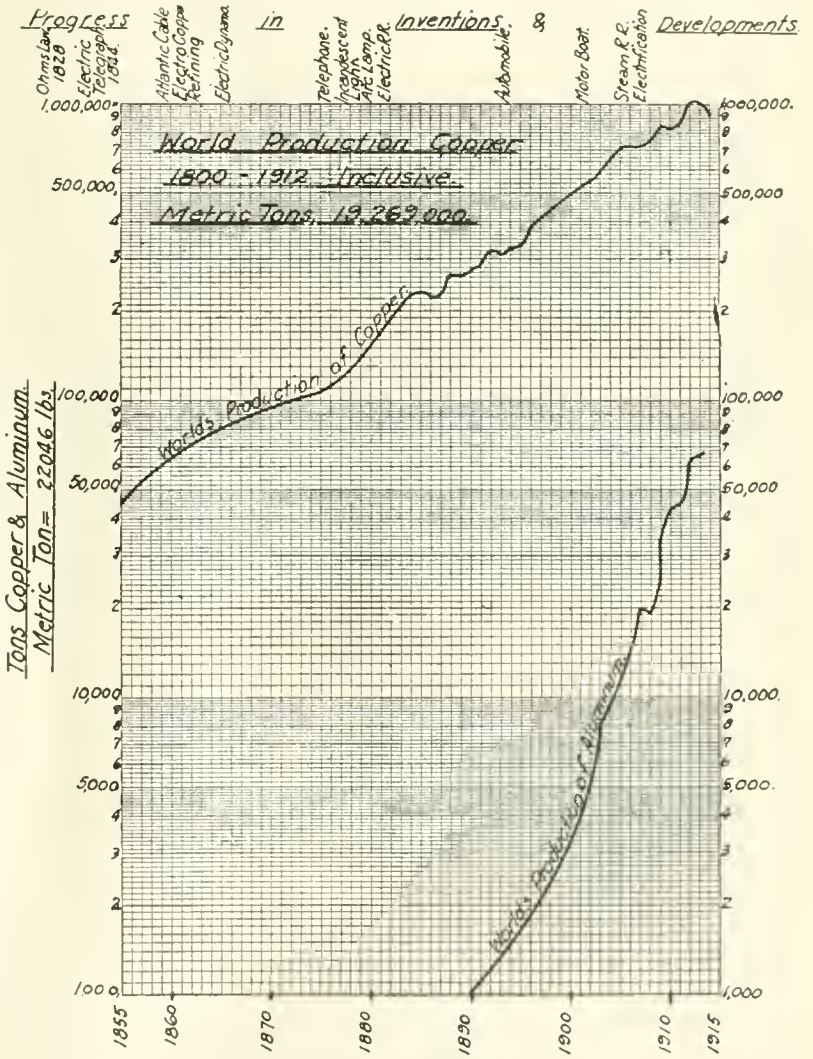
Economics of the World's Supply of Copper

By Thomas T. Read

*COINCIDENTLY with the development of the electrical industry, the consumption of copper has increased at an extraordinarily rapid rate, and is now at its maximum. It is of interest to consider (1) whether this increase will continue; (2) whether resources are available to permit the continued production of constantly increasing amounts of copper. As sub-topics under (1), there are the questions: (a) whether substitutes may not be devised to take the place of copper; (b) whether changes in industry may not be brought about that will perhaps decrease the use of those materials in which copper is now used; (c) whether new uses for copper may not be devised that will increase its consumption. As sub-topics under (2), it is necessary (a) to review the known and probable resources of the world's copper deposits, and (b) to analyze the world's trade in copper in so far as it bears on the economic factors governing the exploitation of these deposits.

(1a) PROBABILITY OF SUBSTITUTES FOR COPPER. The electrical industry absorbs 60 to 70% of the present production of copper, the larger part of it in the form of wire. Aluminum is a strong competitor of copper for long-distance transmission-lines, or wherever aluminum can be stranded with a wire of steel to afford the tensile strength that the aluminum itself lacks. Aluminum is more easily attacked than copper by corrosive agencies of the atmosphere, but as long transmission-lines are most in use in the Rocky Mountain region, where the air is comparatively pure and dry, the importance of this factor is lessened. For telephone and telegraph lines, copper seems likely to hold its own, especially in the Eastern States, since it is resistant to corrosion, and the smaller copper wire is less swayed by the wind and holds a smaller load of snow and ice in the occasional severe storms that are so destructive. It has been suggested that steel wires coated with copper would have greater tensile strength and equal conductivity, but it is difficult to make such a coating sufficiently homogeneous and adherent so that rusting will not take place beneath it, and it is also difficult to produce compound wires at a low cost. Where small wires are necessary, as in winding dynamos and motors, or for electric-light cord, there appears no possibility that copper can be displaced, and the competition of aluminum must be confined to heavy wire.

(1b) POSSIBLE CHANGES IN INDUSTRY. For the present at least, there seems no reason to suppose that the electrical industry will demand smaller quantities of copper, while in a hundred fields of industry the growing use of electrical equipment calls for increasing amounts.



THE WORLD'S PRODUCTION OF COPPER AND ALUMINUM.

(2a) KNOWN AND PROBABLE RESOURCES OF COPPER. The following table shows the copper reserves of the principal mines of the Lake Superior district, as estimated by J. R. Finlay in a report for the State Tax Commission of Michigan in the summer of 1911. The figures given are the recoverable copper, not the total content. Since 1911 the recovery methods have been improved and a leaching process has been devised that is expected

*Abstracted from a paper presented before the International Engineering Congress, in San Francisco, September 20, 1915.

not only to increase the recovery from ore, but also to yield large amounts of copper from old tailing.

Mine	Recoverable copper lb.
Ahmeek	290,000,000
Mohawk	176,000,000
Wolverine	80,000,000
Osceola Consolidated	300,000,000
Allouez	140,000,000
Calumet & Hecla	702,000,000
Osceola amygdaloid	330,000,000
Quincy	260,000,000
Isle Royale	112,000,000
Superior	75,000,000
Baltic	110,000,000
Trimountain	16,000,000
Champion	110,000,000
Lake	40,000,000
Total, July, 1911	2,681,000,000
Deduct production to January 1, 1915.	
Add estimated recovery from tailing	150,000,000

This table includes only those mines that, in 1911, were producing copper at a profit. There are other mines that produce (or have produced) considerable amounts without making any profit. A decrease in working costs or an increase in the price of copper would therefore increase the reserves given above.

Only a few of the other copper companies have published any statement of their ore reserves, but fortunately among these are several of the largest, as shown in the table below:

	Ore in tons.	Copper %	Copper in lb.
Utah Copper	332,500,000	1.47	9,642,500,000
Ray	78,380,966	2.20	3,228,800,000
Chino	94,000,000	1.80	3,384,000,000
Inspiration Consolidated	45,000,000	2.00	1,800,000,000
Miami	20,300,000	2.45	995,000,000
	6,000,000	2.00	240,000,000
	17,200,000	1.21	413,000,000
Nevada Consolidated	41,020,296	1.68	1,374,180,000

Figures for the Anaconda and Phelps-Dodge companies are not available; otherwise, a fair estimate of the known copper resources of the United States might be made.

For foreign companies, even less authentic data are available. The list below gives most of those at hand:

Mine.	Ore Reserves Short ton.	Copper Content %	Copper Content lb.
Chile Copper Co., Chile	280,855,000	2.13	11,936,337,500
Braden Copper Co., Chile	78,000,000	2.8	4,368,000,000
Mount Morgan, Australia	3,125,000	2.55	1,572,500,000
Kyshtim Corporation, Ltd., Russia	356,000	3.00	21,360,000
Spassky Copper Mine, Ltd., Siberia	12,643	20.00	5,057,200
Mount Lyell, Tasmania	2,202,335	0.531	23,500,000
	1,086,112	6.00	130,300,000

These figures are useful only as hints, since the really significant factors are the large deposits that have never been thoroughly explored. Thus the immense copper deposits of the Belgian Congo have never been appraised, since under present conditions no profit can be made, except in working the higher-grade ore. Improved facilities for mining and reduction, a new process, or higher prices for the metal may render immense quantities from these deposits available for industry. It is significant that the largest reserve in the table above, that of the Chile Copper Co., was unknown a few years ago. Large copper deposits exist in southwestern China and are only worked to a limited extent. The figures given for the two Russian companies undoubtedly represent only a modicum of the copper which that country will eventually produce.

(2b) World's Copper Trade. The United States produces more than half the world's supply of copper. Japan, with the next largest output, producing less than one-seventh of the U. S. output. Of our yield about one-half is used in this country and one-half exported, chiefly to Europe, Germany having been our best customer. Japan uses a large part of its output and sells the rest in China and Europe. Much of the Australasian production goes to Europe, and the same may be said of the Mexican and Chilean copper. The copper output of Russia is absorbed in that country; in time Russia may become an exporter. Spain and Canada are also important producers of copper; the output of the other countries is small. It may be said that the general movement of copper, the world over, is toward regions of dense population. Manufactures of copper, on the other hand, tend to flow outward from the densely populated regions. In general, it may be said that such fluctuations in the price of copper as occur in the near future will be due to the relations between demand and immediate supply, and not to any scarcity of copper ores.

Copper and its alloy, bronze, were known and used by prehistoric men. Copper was known before the time of Menes, the first Egyptian King, who reigned at a period possibly as early as 5500 B. C. It is believed that copper was used malloyed for many centuries before the discovery of the use of tin as an alloy for producing bronze, which came into use on account of its greater hardness. At the beginning of the 18th century, Great Britain was making three-quarters of the world's copper—possibly 5000 tons. One hundred years ago the mines of the United States, Spain, Chile, Mexico, Canada, South Africa, Australia, and Tasmania, which now produce 90% of the world's copper, were undeveloped. In the United States, copper was discovered in Massachusetts as early as 1632, and in 1709 a company was incorporated in Connecticut for the purpose of working copper ores. The copper deposits of New Jersey were exploited in 1719. The copper mines of Vermont date from the 18th century. These were the principal sources of American copper until the opening of the Lake Superior mines in 1844. Really important copper mining in the United States dates from 1844, with the opening of a vein near Copper Harbor, in Keweenaw county, Michigan. In 1882 Montana produced its first copper. The copper industry of Arizona was started a decade later.

Points of View From Lake Superior

By P. B. McDonald

THE Franklin mine is trying a circular picking-table in its shaft-house where hand-picking of the ore is being done. Close picking of the ore at the shaft is an innovation in the Copper Country.

Steel is now being manufactured at Duluth in the new plant of the U. S. Steel Corporation. Hibbing, Minn., continues to have troubles; together with several neighboring towns, its saloons have been closed by an old Indian law of 1855.

The Calumet & Hecla group of companies is using ⅞-inch hollow steel for most ordinary drilling. With the longer steels now employed, a 16-ft. length of ⅞-in. steel appears, as one miner expressed it, "as springy as a whip."

The Wolverine mine, which was such a steady profitable producer for so long, was reported a few years ago to have its ore practically exhausted. Then the policy of seeking for copper in the foot-wall by drilling with small sinker-drills was adopted with such success that it is now announced that the mine has 15 or 20 years of life ahead, much of which time will be consumed in working from the bottom back to surface, prospecting the foot-wall in the old stopes. The report that the Stanton interests, who control the Wolverine and Mohawk, intend to consolidate the White Pine Extension with the Wolverine is officially denied, although Theodore Dengler will serve as manager of the three mines.

Calumet township has shown such an increase in births recently that for the year 1915 it registered approximately one-tenth of the total number of births in the State of Michigan. It is axiomatic that the statistics for marriages and births in the Copper Country rise and fall in the wake of the price of copper.

A mine-superintendent in the Copper Country recently remarked: "Our output hinges on the speed of tramming, yet if we put an extra man on each car, two men would work while the third loafed." In many of the copper mines the tramming is so scattered on twenty or thirty levels that close supervision is difficult. Mule or electric haulage never obtained much popularity in this region, such as the latter has on the Iron Ranges, because of the difficulty of concentrating the tramming; the Winona mine recently put in mules for underground haulage.

E. W. Walker, who returned to Michigan from Arizona several years ago and made a record at cutting costs and producing copper at the Mass Consolidated, is now in charge of the Lake mine. Six or seven years ago Lake was the sensation of the stock speculators in the Copper Country, partly because of spectacular showings of copper and partly because of the connection of the Pryor family with the company. Mr. Walker's plan of campaign to rehabilitate the Lake mine will be based upon the same mixture of progressiveness and conservatism as characterized his management of Mass.

The White Pine mine down in the wilderness of the Porcupine mountains used to be more difficult to reach from Houghton than was Chicago or Milwaukee. With the recent completion of the branch railway, coal and supplies are being shipped to the locality and a settlement is springing up near-by; the company is also taking advantage of the rail-transportation to improve the equipment at the mine.

The Kitchigami Gold Development Co. is a recent venture of Lake Superior people to operate in the Kirkland Lake district of northern Ontario. The directorate includes John Daniell, Dr. John McRae, Chas. Chynoweth, James T. Fisher, and Edwin J. Hall, all of Calumet, Henry Baer of Hancock and John A. Doelle of Houghton. C. W. Botsford, a geologist of experience, is in direct charge of the work, which will consist at first of diamond-drilling to cut extensions of neighboring gold-bearing veins. The company was organized under the laws of the State of Arizona with a capital of $300,000 divided into 150,000 shares of $2 each; public participation in the stock holding was invited. Four mining claims, approximating 160 acres, have been secured in the part of the Kirkland lake district adjoining the Foster-Costello group. Every once in a while Lake Superior people take a chance on ventures in the West or North, and have picked some notable winners.

The year 1915 was an extraordinary one for the Copper Country, the output of copper being 259,352,000 lb. This was the largest production of copper that Michigan ever made, exceeding the great years of 1905 and 1909. As compared to the copper yield of Arizona in 1915, which was the enormous figure of 450,000,000 lb., Michigan's figure seems small, but the State of Arizona is many times larger than Keweenaw peninsula, and embraces several copper mining regions. Montana's output of copper in 1915 was 275,000,000 lb. Of Michigan's production the Calumet & Hecla Co. furnished 72,000,000 lb. or less than one-fourth, which was the company's biggest output in six years. It is interesting to note that the so-called Calumet & Hecla subsidiaries, produced slightly more than the Calumet & Hecla. Evidently the policy of expansion adopted by the C. & H. several years ago will be profitable. It should be remembered, however, that only a portion of the stock of the subsidiary companies is held by C. & H. Dividends from the Lake mines had dwindled a good deal since the happy days of ten years ago, and the large returns of the last year are all the more deserved when the lean months of the strike are considered.

CONCENTRATES

Readers of the MINING and Scientific PRESS *are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.*

MINE FOUNDRIES should be well ventilated to get rid of the dust, steam, and smoke that always accompanies molding and casting metals. Small furnaces should have hoods attached.

MANGANOID STEEL BALLS and lining have been found to be the most efficient for Hardinge re-grinding mills at the Winona mine, Michigan. They are superior to the flint and silex imported from Europe.

WORN-OUT TUBE-MILL LINERS of the Osborn type on the Rand are being successfully used as liners for launders, ore-bins, feeder-chutes, and mortar-boxes, also as fire-bars for assay and melting-furnaces.

JOURNALS are best lubricated by having the rubbing surfaces constantly submerged in a bath of oil; it is not necessary that the whole surface be submerged. The same result is accomplished by chains and rings encircling the journals and dipping into oil-pockets.

FLY-WHEELS are commonly made of cast iron as it is cheap. With high speed this material is not safe. Some heavy fly-wheels are made of steel-plates (perhaps a dozen, each ½ in. thick) securely riveted together; such a fly-wheel might be used on a motor-generator set.

THE WASTE of heat supplied an open-hearth furnace as fuel gas and combustible elements of the charge is 45%. Boilers placed in the flues will reduce this loss by 50 or 60%, by the generation of steam for power. An 85-ton furnace will produce 386 b.hp. There are several difficulties in the operation of a boiler in this way.

THE BASIC-LINED copper converter is now well established. It gives splendid service. At the Old Dominion smelter, at Globe, Arizona, a converter of this kind was taken off the stand, early in December, after having been in continuous use since July 1913—a run of 30 months. During that time it had produced 70,000,000 pounds of copper.

SURFACES of machinery that are subject to heavy work and wear should be case-hardened. This is done by penetrating the surface of the steel by carbon. The best natural carbonizers are granulated bone, charred hoofs, leather, beet-sugar pulp, and crude raw sugar. Artificial carbonizers are made, but their effect is not considered equal to the natural ones.

HYDROCYANIC ACID GAS is used for fumigating various things, largely fruit trees. The gas is made in the orchard in a machine on wheels. The cyanofumer consists of two tanks, one above the other: in the lower one is H_2O and H_2SO_4, in the upper KCN solution, and by means of a pump the required quantity of solution is forced into the acid, generating gas instantly. This is sprayed onto the trees.

SOME ENGINEERS consider ball and roller bearings not successful or commercially practicable for heavy shafting. This type of bearing shows good results in low friction losses when new and when kept in good condition, but give trouble if not frequently examined. A well-designed babbitted self-oiling bearing with chain or ring, is considered very reliable. It is simple, has low first cost, little wear, small oil consumption, and the metal lasts for years.

SPECIFIC GRAVITY of metals is of interest at this time of disturbance and new adaptations in metal economies. Tungsten's specific gravity is unusually high, being 17.3, which is nearly equal to gold of 19.3, and which exceeds that of mercury, 13.6. Magnesium, which German scientists are said to be advocating as a substitute for aluminum, is only 1.75, compared to 2.7 for aluminum, which in turn is three times lighter than copper with 8.8. Cobalt and nickel are close to copper. Chromium at 5 is lighter than steel at 7.8; while zinc at 7 is nearly equal to tin at 7.3, but lighter than lead at 11.4. Manganese is from 7 to 8; silver is 10.5.

AMYGDALOID, BANKET, conglomerate and pudding-stone are terms closely allied. The first is given to an igneous rock containing rounded cavities, caused by bubbles of steam in the original lava, now filled with secondary minerals, such as quartz or calcite, or lined with zeolites. Amygdaloid comes from *amygdalé*, the Greek for almond. Banket is the Boer word for almond cake, and was given by them to the conglomerate on the Rand. Conglomerate comes from the Latin *conglomeratus*, heaped together, which is derived from *cum*, with, and *glomus*, a ball. It is the more scientific equivalent of pudding-stone, given in the early days of geology to a rock formed of consolidated pebbles.

A 'POSSUM,' as used in the oilfields of California is intended to prevent wear on both the cable and casing, by keeping the cable from rubbing or striking the sides of the casing. They are especially effective where the hole takes a considerable turn from the perpendicular. These possums are usually from 1½ to 2 in. thick, and from 12 to 14 in. long, tapered at each end to allow a rope knife to be run over them when necessary. The wrapping or material of which they are constructed is usually rope-yarn, but tarred marlin is better; electric tape can also be used. The number put on a cable, and the distance between them, depends upon the conditions existing at each well. The possums should be kept oiled or 'doped' with some lubricant. This idea came into use in California about 10 years ago, and it is gradually spreading to other oilfields. As possums will run over the crown-pulley and wind on the bull-wheel shaft, there are no bad features in connection with their use.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TUCSON, ARIZONA

FLOTATION TESTS ON ARIZONA ORES.

It is officially stated that a considerable amount of experimental work in oil flotation is being done this year at the University of Arizona, at Tucson, using the machine as shown in the accompanying illustration. The machine used is of the modified Hoover type, having an agitation chamber and spitzkasten, with a suction created by the agitator arms returning a portion of the pulp for re-treatment. The machine is in a series of three chambers, connected by glass tubes, and is arranged for mechanical agitation in varying speeds, as well as air agitation, where the air is forced through a 200-mesh screen, or a combination of both. The machine is arranged for continuous action, or any chamber may be operated separately. The chambers have glass fronts and glass connecting tubes, in order to observe the action. So far, molybdenum ores have received special attention, and very

EXPERIMENTAL FLOTATION PLANT AT ARIZONA SCHOOL OF MINES.

satisfactory results with selective flotation, in the separation of molybdenite from copper and iron sulphides, have been obtained with eucalyptus and creosote oils. Good results have been obtained with as low mixtures as 0.05% oil.

A large part of the experimental work is being done on mixtures made up from pure oils, in order to determine, if possible, some relation between the oils used and the mineral character of the ore. Experimental work is also going on in an effort to determine whether or not there is any relation between the mineral faces, as determined by varying the crushing. Over 80 oils are being used in the experimental work. The whole group of experiments is designed with a view to determining 'why is flotation?' The greater part of the work is being done by H. J. Stander, assisted by P. E. Joseph and E. W. Ames, under the direction of the Arizona State Bureau of Mines.

The Arizona State Bureau of Mines at Tucson has so far published 10 bulletins dealing with the mining industry of Arizona; these should be of interest to those engaged in mining, and the Bureau will be pleased to send them to anyone desiring the same. The following bulletins are now in process of preparation: 'Tungsten,' 'Mercury,' 'Magnesite,' 'Workingman's Compensation,' 'How to Sell Ores.' The February Safety Bulletin, Safety series No. 1, is to hand.

JOPLIN, MISSOURI

BRIEF REVIEW OF THE PAST YEAR IN THE ZINC-LEAD AREA.—WORK OF STATE MINE INSPECTOR EFFECTIVE.—NEW PLANTS OF SOUTH CARTERVILLE DISTRICT.—ZINC AND LEAD NOTES.

With an aggregate value of $26,000,000 for zinc and lead ores shipped from the Missouri-Kansas-Oklahoma region in 1915, all previous records were easily broken, the best year prior to 1915 being 1912, when the total output was $18,043,479.

Zinc sulphide concentrate constituted the larger part of the tonnage, and commanded the highest price per ton of any of the ores shipped, the highest price having been reached in the week ending June 12 when $135, basis of 60% metallic zinc, prevailed for a greater part of the high-grade.

Shipments of the various ores from the district for the year were 286,000 tons of blende, 21,000 tons of calamine, and 45,000 tons of galena, the average price per ton for blende being $76 for the year, compared with $51 in 1912, the previous high year. Lead averaged $55 per ton.

The new year dawns with 60% blende worth $85 to $115 a ton, compared with $48 to $52.50, calamine at $60 to $75, basis of 40% zinc, compared with $22 to $25, and $70 for galena, compared with $47 at the beginning of 1915. During the early months of the year the market displayed remarkable fluctuations. The rises and falls of the ore market uniformly reflect the movements in spelter.

The prosperity in the zinc-smelting industry throughout the United States has been reflected to a great extent in the mining industry of the local district, although the greatest margins of profits have been reaped by the smelters. For instance: the smelter procures for an average of $100 a ton, ores that yield metal valued at $170. Much of the metal made from Joplin ores realize more than the quoted price on prime Western grades; hence the margin of profit to the smelter is even greater than would appear at first glance.

Following in the wake of the higher and steadier ore prices, the local mining field has enjoyed an epoch of activity never before equaled. Not only have new mills 'sprung up' in all parts, but new towns have sprung up from nothing; and where, a year ago, there was was no sign of human habitation nor activity save, perhaps, a caravan of prospecting drills, prosperous, thriving and busy communities now exist. Picher and Cardin, Okla., are striking examples, the former being the 'baby' camp of the north-eastern Oklahoma

zinc and lead fields. Commerce, Okla., now boasts of one of the best weekly newspapers in Oklahoma, large foundries, hotels, modern brick buildings, macadamized streets and a population of 2500. All these little places dot the prairies in the extreme northeastern part of the state and constitute what is known as the Miami district, due to the fact that Miami is the largest town there, and was the only town there when the first mining was done about eight years ago.

Other portions of the district, reaching as far as Aurora, Lawrence county, on the east, down to Granby, in Newton county, on the southeast, Alba and Neck City on the north, Galena, Kan., on the west and Miami on the southwest show evidences of the wave of prosperity that is sweeping through the district. Foundries and machineshops of all cities in the district are unable to meet the demand for equipment, and supply houses are doing the biggest business they ever did. Mine labor is at a premium, and workmen by the thousands are getting wages of $3.50 to $4 a day, while some are making more than this.

Efforts of the mine inspectors for this district of Missouri have been devoted not only to improving the working conditions in the mines and making work generally less hazardous, but also to making the surroundings of the workmen more elevating and to improving the sanitary features. In their report to the chief state mine inspector, Geo. Hill, the three inspectors of this district will set forth the work they have accomplished during the year just closed. The local inspectors are I. L. Burch of Joplin, C. M. Harlan of Carterville, and W. W. Holmes of Webb City. They played a prominent part in the organization of the Southwest Missouri Mine Safety and Sanitation Association, consisting of mine operators who meet every Thursday at a noon dinner at Webb City. Much good has been done by the Association during the few months that it has been in existence. Mine owners, almost without exception, have shown a desire to co-operate with the inspectors in the enforcement of State laws. One result is that in nearly all the hard sheet-ground mines water-pipes have been fitted up to all headings, and holes are sprayed to prevent the circulation of rock dust through the drifts, thus greatly eliminating one of the principal causes of miners' consumption. The building of better 'dog-houses' has been started by many of the larger companies, while others are to follow suit. At the American Zinc, Lead & Smelting Co.'s property at Carterville a new dog-house has just been finished. It is 112 ft. long by 30 ft. wide, heated with steam, and has 248 ventilated lockers. The building is floored with concrete, while at one end is a bath department equipped with numerous showers. At the Scott mine, Duenweg, Mo., the company has provided for the comfort of its men to an exceptional extent, a large swimming-pool in which the water is changed every 24 hours having been constructed in the dog-house. The mine inspectors have put the ban on boulder 'popping' during working hours, and stress has been laid on the importance of having all roofs properly trimmed and examined regularly each day to eliminate the probability of accident from falling slabs.

Two new mills in the South Carterville district will be working before the end of January. Both are being constructed by Mattes Bros., who have two separate leases of 20 acres each on property of the Zinc Corporation of Missouri, of which T. J. Franks is president. One mill will be on what is known as the Carey lease, a tract of land that was only recently drilled and opened with shafts and drifts. Disseminated ore was encountered at a depth of 110 ft., and continued down to 165 ft., while beneath this two shoots of sheet-ground, each 10 ft. thick, have been blocked out. The ore will yield about 3% blende and galena. The mill on this property will be of 300-ton capacity per shift, and will be ready before the other plant which is on what is known as the McGregor tract, where only a sheet-formation is to be worked. The Kirkwood, a 360-ton mill, is a recent one to begin work on the same land, while on the Connor land to the west the new plant of the Googie Mining Co., which was recently sold to the National Lead & Zinc Co., of Boston, for $100,000 cash, is now producing steadily. A number of other new mills have recently begun operations in the South Carterville district, and as most of them are of large capacity the development in this field is considered of much importance.

The Reeds, Mo., centre in the eastern part of the district is being heard from again through the activities of the United States Smelting company, which recently took over the old Ravenswood lease of the Cornell land, and constructed thereon a concentrating plant that ranks well up with the largest of the district, having a reported capacity of 500 tons per shift. The ore in that field occurs in disseminated bodies, both in hard and soft ground. No blanket formations have been blocked out. Another mine at Reeds to be started in the near future is the Jack Rabbit, which was a small producer some years ago. Improvements include the construction of a large concentrating-plant if prospects are satisfactory.

The Anna Lee mill of 200-ton capacity is being moved from the Spring City, Mo., to the Lincolnville district, where it will be re-built on a lease of the Old Abe Mining Co., the fee to which was purchased recently by S. W. Van Dyne, who was operator of the Anna Lee mine. New development on the Old Abe tract is reported to have revealed a sheet formation at a depth of 70 to 90 ft., the ore being milled easily, due to the fact that it does not have a tendency to be 'chatty.'

Prospect work on city lots on North Jackson avenue, Joplin, within a stone's throw of some of the finest dwellings in the city, is revealing 'pay-dirt' at a depth of 70 to 90 ft. in soft ground. One shaft is already into ore, a hand-jig plant is at work, and steady turn-ins of concentrate are being made. A drill-rig is now working even closer to the residences than any of the previous work, and new strikes are reported. The work is on property of G. S. Clemens, a Joplin dentist, who was holding the land for residences. Its value was materially decreased recently when several acres of mining land caved in, the brink of the pit coming to within a few feet of his choicest lots. Thereupon he decided to mine the property in preference to holding it for sale. His royalties already have more than compensated him for his decision.

The price of zinc-blende at the beginning of the new year is $80 to $110, basis of 60% metal, compared with $48 to $52.50 at the beginning of 1915. Every indication points to continued strength of the market.

PLATTEVILLE, WISCONSIN

Condition of the Zinc Industry in December.—Zinc, Lead, and Pyrite Production in 1915.—New Plant.

In spite of bad weather during the latter part of December, unspeakable wagon-roads, intermittent electric-power supply in the southern districts, production and deliveries were large. There was no lull during the Christmas season, something unknown here. Building continued, while drill-rigs and labor to operate them were almost impossible to obtain. Zinc ore maintained a high price. Top grades of refinery products were the subject of keen competition among the more prominent buying concerns, the base range fluctuating between $110 to $115 per ton, 60% metal, an increase of $30 to $35 during the month. All grades were in constant demand. When good roads are constructed, and motor-trucks used for haulage, the outlying districts will be able to reach the market promptly. Producers of lead ore had advanced offerings, sales being made near the close of the year at $72 per ton. Sales were light, as zinc is now the ranking ore of the field, and miners everywhere are devoting their energy to the recovery of zinc ore exclusively. Shippers of iron pyrite continued deliveries of fines from separating-plants, but the turn-in was light, some product being carried over. While the crude-ore producers had been curtailing production, the loss in deliveries was

made up from sales from refineries, and the figures at the close of the year will compare favorably with the output reported for 1914. Carbonate of zinc ore producers observed rather wistfully that quotations during the month had mounted to a high price, yet found little demand. As previously mentioned, the New Jersey Zinc Co. practically controls the districts in which this class of ore occurs, and it is not disposed to pay abnormal prices for ore to make a cheap commodity like oxide zinc. Competing compounds in the metal branch of the smelting industry are chary of invading these districts for fear of the reprisals that may be made at other points. The Lanyon Zinc Co. and the Picher Lead Co. have both displayed temerity in picking up some choice ore but the yield for the season is being carried over. In the Joplin district sales were reported at $85 per ton and as low as $65 for less desirable production; these figures generally govern quotations for the Wisconsin field, where the miner practically starved out would be willing to accept a much lower standard for a steady outlet for his labor and investment.

Ore deliveries during December were as follows:

Districts.	Zinc pounds.	Lead pounds.	Pyrite pounds.
Benton	15,124,000	458,900	80,000
Mifflin	7,860,000	222,000	.....
Galena	4,346,000	.....	.....
Cuba	3,363,000	.....	3,376,000
Hazel Green	3,162,000	.....	.....
Platteville	2,900,000	.....	696,000
Linden	2,816,000	.....	.....
Shullsburg	1,298,000	162,200	.....
Highland	826,000	50,000	.....
Montfort	248,000	.....	.....
Potosi	150,000	.....	.....
Mineral Point	110,000	.....	.....
Total	42,203,000	893,100	4,152,000

The gross yield of crude concentrates from all mines for the month totaled 35,515,600 lb.; net refined ores from separating-plants and from mine to smelter direct for the month, 22,712,000 lb. As usual, the Mineral Point Zinc Co. led in the amount of zinc concentrate handled and shipped to smelter at DePue, Illinois, 4,153,000 lb. of 60% 'jack.'

Summing up operations for 1915 in this region there was produced a total of 331,741,540 lb. of crude concentrate, against 261,594,330 lb. in 1914. Shipments of ore out of the field, the true barometer by which the value must be ascertained for the past year, aggregated 212,355,750 lb., compared with 166,136,300 lb. in 1914, or 23,110 tons more than in 1914. This gain is all the more to be appreciated since more high-grade ore reached smelters from Wisconsin mines than ever before, due to the extensive additions of electrolytic zinc ore-separating plants built during the second half of the year. Twelve are now at work, against four at the beginning of 1915.

Lead production in 1915 was 8,320,000 lb., against 4,970,270 lb. in 1914.

Shipments of iron pyrite were under the figures published for 1914, which reached a total of 31,520,110 lb. A gain was made in value, however, since nearly all of the product sold last year came from separating-plants as fines recovered in electrostatic separation, which command a higher figure than crude pyrite. The Wilkinson mine, the largest single producer of pyrite in the Benton district suspended production when its big surface equipment was destroyed by fire early in the year. The profit in handling the crude ore was so small that the owners of the mine concluded to give up the lease.

The building program during the year brought into active co-operation with old establishments 15 new power, mining, and milling plants. Seven others are in various stages of construction, four of them coming into active service soon after the first of 1916.

WASHINGTON, D. C.

PROGRESS OF MINING LAW CODIFICATION IN CONGRESS.

While the codification of the Federal mining laws remains in a favorable position, a marked change as to how it is to be done is manifesting itself, and is likely to go through Congress. All previous bills have contemplated the creation of a commission on codification independent of Congress and appointed by the President, this commission to be composed of experts in mining law and other mining matters, and to take evidence in various parts of the country and make its recommendations to Congress. The bill of Representative Taylor of Colorado proposes the appointment of a commission of five members having knowledge and experience in mining law and the industry, with $25,000 at their disposal for expenses; that of Senator Smoot of Utah, which has been favorably reported by the Senate committee on mines and mining, proposes a commission of three members, two of whom shall be lawyers of considerable mining experience and one a mining engineer, the commissioners to receive $500 per month while at work, and having at their disposal $25,000 extra for expenses. A bill has also been suggested for a commission more representative of the mining industry, as recently recommended by mining men assembled at Washington. It appears that none of these bills are satisfactory to men of influence in the House, and they are declaring decided opposition to them, proposing that the commission to be appointed shall consist of no one not connected in Congress; in fact be made up of members of the Senate and the House familiar with Federal mining law. It is asserted that Congress contains great mining lawyers, such as Senators Walsh of Montana and Thomas of Colorado, and Representative Taylor of Colorado. While such talent is available in Congress, it is asserted, it would be foolish for Congress to go outside to form a commission, which, after all, could only make recommendations that Congress would have to review before enacting them into law. Besides it would all be more direct. As a matter of legal fact Congress would have to codify the laws. It can reject *in toto* the recommendations of any commission. It is even suggested that no commission be appointed at all, but that a joint committee of both Houses, composed of the two mining committees, be authorized to codify the laws and report to Congress. All salaries would be saved thereby, and little incurred. There could be nothing more direct in the codification of the laws. It is asserted that under such auspices the work of revision and of having hearings could be started at once. The mining committees have nothing much to do anyway. All the best legal talent in mining in Congress could be put on the committee. It is thought that such an appeal would carry more weight in Congress than any other that might be made. It is the method Congress ordinarily employs in revising the laws of the country. For some years it has had a joint commission of members of both Houses revising and codifying the general laws of the land, and good work has been done. The same arrangement of committee has also revised the printing laws of Congress. The committee could have its hearing, if any were needed, in the summer, going about the country, but the necessity of such hearings is doubted, but if expedient, everything could be got out of the way by December next. It is asserted that even a commission of independent men could not report its work any earlier. It is said that the mining laws are not so very voluminous. It seems as if this is the course the legislation is likely to take. Since Congress re-assembled in January, hearings have been held by the House committee on mining at which Senator Walsh, Van H. Manning, director of the U. S. Bureau of Mines, and J. F. Callbreath, secretary of the American Mining Congress spoke at length on the need to codify the laws. It is the House committee that is expected to report favorably the new kind of bill discussed above. In the opinion of Washington, it is not so much the personnel of the committee or commission that matters, so long as some

committee of commission of ability is appointed and goes ahead with the work desired. And seemingly, it is declared, the more direct the work is the better it should prove and the sooner finished.

EL PASO, TEXAS

DETAILS OF THE RECENT OUTRAGE IN MEXICO.

On January 10 a party of American mining men on the way from Chihuahua to the Cusihuiriachic Mining Co.'s property was attacked and murdered by Villa bandits. The only survivor was Thomas B. Holmes, who prepared the following statement for transmission to Washington:

"Our train left Chihuahua City Monday morning, January 10 at about 11 o'clock. Train was stopped at or about the ranch Baeza, a point about five miles west of Santa Ysabel, between 1:30 and 2 o'clock that afternoon. While the train was standing at the station of Santa Ysabel two armed Mexicans rode by and scrutinized the train. The Mexican passengers at Santa Ysabel told me afterward that the riders had inquired if there were any soldiers on the train. At the point of the massacre our train was stopped in a cut so that the last car was just inside of the cut. We were stopped by another train—the front trucks of one coal car being off the track. This was the first we knew of a train preceding us. There was nobody to be seen around the train in front. When our train stopped, Newman and I were sitting together, and Evans came up and looked out of our window. Evans, Newman, MacHatton and I then got off the train. Watson was either getting off or about to do so, behind us, when I looked back and saw him. Just after alighting I heard a volley of rifle shots from a point on the other side of the cut and just above the train. Looking around, I could see a bunch of about 12 or 15 men standing in a solid line, shoulder to shoulder, shooting directly at us. They were 50 to 75 feet away. The coach cut off my view, so I could not see how many bandits there were. The depth of the cut on the side near the Santa Ysabel river at that point was about 12 ft. On the other side it was much greater. To the rear of the train was an embankment declining toward the river. Watson, after getting off, ran toward the river. MacHatton and I followed. MacHatton fell. I do not know whether he was killed or tripped. Watson kept running and they were still shooting at him when I turned and ran down grade, where I fell in some brush, probably 100 ft. from the rear of the train. I lay there perfectly quiet and looked around and could see the Mexicans shooting in the direction at which Watson was running. I saw that they were not shooting at me and, thinking they believed me already dead, I took a chance and crawled into some thicker bushes. I crawled through the bushes until I reached the bank of the stream. I then made my way to a point probably 100 yards from the train. There I lay under the bank for half an hour and heard shots by ones and twos and threes. I did not hear any sort of groans or yells or cries from the Americans. I then continued farther under the bank, wading the stream part of the time until I reached a point probably 200 yd. from the train. There I remained a half or three-quarters of an hour. Later, after going to several ranch houses and picking my way cautiously for several miles, I met up with an unknown Mexican, who directed me to Chihuahua City. I reached Chihuahua City Tuesday morning at about 7:30. The foregoing facts are of my personal knowledge."

MAP SHOWING SITUATION OF EL PASO AND CHIHUAHUA.

The previous story of the party being lined up naked before being shot is not confirmed by Holmes.

The following are the victims:

PRINGLE, C. A., San Francisco.
WATSON, C. R., El Paso.
WALLACE, W. J., El Paso.
ANDERSON, MAURICE, Chihuahua City.
COY, B. W., El Paso.
COUCH, A., Chihuahua City.
EVANS, T. M., Chihuahua City.
ENDERS, JOE, Hayden, Arizona.
HALL, ALEXANDER O., Douglas, Arizona.
HASSE, E. C., Miami, Arizona.
JOHNSON, THOMAS, address unknown.
MACHATTON, R. P., El Paso.
NEWMAN, G. W., El Paso.
PEARCE, W. D., Los Angeles.
ROBINSON, E. L., El Paso.
ROMERO, M. B., El Paso.
SIMMONS, R. S.
WADLEIGH, CHARLES, Bisbee, Arizona.
WOOM, J. W., El Paso.

Romero was a Mexican, Couch a Canadian, and Robinson an Englishman.

AUSTIN, TEXAS

MINERAL RIGHTS.—COPPER DEPOSITS.

It is thought that under the recent construction of the State mining law by the Attorney-General's Department, in which it was held that areas purchased under the land law of 1883 carry the mineral rights with them, and that such lands are not subject to being prospected under the mining law of 1913, promises to have the effect of retarding mineral development of such ground in the mining district of west Texas. A great number of tracts were sold under this law, classified as agricultural and grazing, and unconditional patents were issued covering many of them, but recently the State Land Commissioner has received many requests for the leasing of the mineral rights on the land in question, but under the ruling of the Attorney-General's Department applications to prospect this land for minerals cannot be granted.

The copper deposits in the 'red beds' of Hardeman, Knox, King, Haskell, Fisher, Baylor, Throckmorton, Jones, Wilbarger, Taylor, Wichita, Archer, and Clay counties, north-central Texas, are discussed by Louis M. Richard in *Economic Geology* for November-December, 1915. The area is composed of beds of limestone, gypsum, sandstone, shale, and clay, the surface being at an elevation of 1800 ft. above sea-level.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Antimony production of this district is to be aided next season by the Northern Commercial Co., which has arranged to act as agents for shipments to the United States, from Fairbanks to the market. $20 per ton will be advanced on ore at the point of shipment to help finance producers. George Coleman is agent at Fairbanks.

ARIZONA

Cochise County

Six feet of $44 ore has been cut at 220 ft. in the Commonwealth Extension at Pearce. The shaft is being sunk two feet per eight-hour shift.

Greenlee County

A parade of over 1000 miners took place at Clifton on January 6; there was no disturbance. Assessment work has been completed at the Detroit claims. Some correspondence has passed between the companies' managers at El Paso and the strikers' committee, but without result.

It was reported on January 12 that the strikers had broken away from the Western Federation of Miners.

Mohave County

In the Big Jim mine the 400-ft. level cross-cut has passed through 50 ft. of formation, 22 ft. of which is good ore.

A station is being cut at 900 ft. in the Gold Road, while a winze is to be sunk to 1400 feet.

Drilling at the Copperfield Porphyry mine has passed through 33 ft. of good copper ore.

Yuma County

'A Reconnaissance in the Kofa Mountains, Arizona,' is the title of Bulletin 620-H of the U. S. Geological Survey, by Edward L. Jones, Jr. This isolated range is in the centre of the county. It covers an area of 200 square miles. The Kofa mining district is in the southern part of the range. The shipping point for two of the mines is Mohawk station, 45 miles distant on the Southern Pacific line, but since they were closed, Dome, 50 miles away, is more accessible. The ore deposits consist of gold-bearing brecciated zones and veins in andesite, copper replacements along sheer-zones in granite, disseminated galena in monzonite porphyry dikes, and placer deposits. In the Kofa district are the King of Arizona and North Star mines. The former, up to closing in 1910, produced bullion worth $3,500,000. A 225-ton mill was operated. Up to 1911 the North Star yielded $1,100,000 from milling and cyaniding. In both cases the ore became too low-grade to be profitable. Only assessment is being done around Ocotillo. In the Alamo district, in the north part of the range, prospects are considered encouraging.

CALIFORNIA

Nevada County

Owing to snow in the ditch system of the Pacific Gas & Electric Co., the water supply of the Grass Valley district has been cut off, resulting in shut-downs.

The old Phoenix mine on Gold flat, one mile south of Nevada City, is to be re-opened by J. A. McKennie of Los Angeles, formerly of Cripple Creek, Colorado.

San Bernardino County

With a capital of 500,000 $2 shares the Mojave Tungsten Co. has been incorporated under the laws of the State of Delaware, with head office at 165 Broadway, New York. The engineer is Foster S. Naething and assistant superintendent L. L. Draper. The company is to develop 12 tungsten claims in this county, 19 miles from Roach, Nevada, on the railroad. A good deal of work has been done, opening high-grade ore. Between No. 1 and 2 shafts is 1500 ft. of ore, as exposed by trenching. The ore will average 4% tungstic trioxide. The present equipment is satisfactory. A concentrating-plant of 25-ton capacity per eight-hour shift is to be erected at once. With an expenditure of $10,000 to $12,000, 300 tons of 4% and 5 tons of 20% ore can be extracted monthly; this would yield 20 tons of 60% concentrate. One hundred and twenty tons of low-grade unconcentrated ore has been sold, yielding enough to pay for the new plant, etc. The company will lease parts of its property.

Near Blythe junction on the Santa Fe railroad, 30 miles from the Colorado river, on the branch between Los Angeles and Phoenix, Arizona, is the Arica property of the Assets Realizing Mines Corporation, of Los Angeles. The main shaft is down 508 ft. Ore developed and on dumps is estimated to be worth $629,331. Probably large bodies of copper-gold ore will be opened. A 100-ton mill, consisting of a crusher, rolls, Hardinge mill, and a continuous-decantation plant is being erected.

Santa Clara County

A new deposit of cinnabar is reported by E. O. Waldron and A. E. Eaton near San Jose. A 25 or 30-ton furnace will be erected in the spring. About 10 men will find employment.

Shasta County

Four zinc claims up Cedar creek from Ingot, have been sold to F. L. Harrington of Oakland and W. H. Frickilton of San Francisco. The property is known as the Macumber.

With a capital of $100,000 the California Chrome Co. has been organized by M. F. Hurlbut, Duncan A. McLeod, S. W. Molkenbuhr, Thomas W. Firby, and Charles F. Ryan, of San Francisco and Oakland. The mine is near Castella.

The owners of the Golden Jubilee mine, eight miles from Carrville on Coffee creek, are to employ over 40 men within the next two months, according to the superintendent, J. C. Boddiker.

Sierra County

On January 9 two large snowslides came off the Sierra Buttes mountains above Sierra City, and swept away the compressor-house, part of the stamp-mill, and other equipment of the Sierra Buttes Mining Company.

COLORADO

'The Colorado Workmen's Compensation Act' was the subject of an address delivered by Wayne C. Williams, of the Colorado State Industrial Commission, at the Colorado School of Mines at Golden on November 5, 1915. The Act became law in April last, and Mr. Williams considers it the most salutary and important piece of legislation ever enacted into law in the State. Accidents, benefits, compensation, and insurance were well discussed. The Golden Cycle and Portland companies at Cripple Creek have made admirable arrangements for compensation.

Boulder County

At the towns of Nederland, Lakewood, Stevens camp, Hummer gulch, and Boulder Falls there are hundreds of men at work in the tungsten mines, and there is a constant stream of prospectors and mining men examining and negotiating for property. Transportation of passengers is smaller than two months ago, but there is a material increase in freight shipments. It is rumored on good authority that the railroad company will build a branch down to the mills at Nederland as soon as possible. The line may be extended to Lakewood and thus secure a part of the freight between the mines and the mills of the district.

Clear Creek County

During 1915 the Imperial Consolidated company shipped 1125 tons of smelting ore and concentrate, assaying $85 and $50 per ton respectively. The sampling-plant at Georgetown received most of it.

Company and lessee work in the Mineral Chief mine is reported to be satisfactory.

An important development is reported by the J. D. L. Leasing Co. at Bellevue mountain, where a drift from a winze below the Big Five tunnel has opened two feet of $125 gold-silver ore. Two shifts are working.

Custer County

The Marion Mining & Mills Co. of Denver has erected a flotation-plant in the Greenhorn range, 27 miles from the D. & R. G. line. The plant will treat 100 tons of tailing from concentrators. The ore contains 15% zinc, the tables making a 48 to 55% concentrate.

Lake County (Leadville)

The Iron-Silver Mining Co.'s Moyer mine is shipping 1500 tons of zinc, lead, and iron sulphide ores per month; its Tueson mine produces 1600 tons of zinc-lead sulphide. Lessees are mining zinc carbonate. G. O. Argall is general manager.

The *Carbonate Chronicle* gives the following figures as the output of Leadville in 1915:

Classes of ore.	Tons.
Carbonate	27,756
Iron and manganese	43,714
Sulphide	219,763
Zinc carbonate and sulphide	196,890
Silicious	44,094
Total	532,217
Total in 1914	502,617

Product.	Quantity.	Value.
Gold, ounces	115,121	$2,379,551
Silver, ounces	2,733,646	1,361,355
Lead, pounds	18,534,052	865,540
Copper, pounds	2,254,268	387,059
Spelter, pounds	74,208,015	10,276,725
Manganese, tons	6,250	625,000
Total		$15,895,230
Total in 1914		$9,087,628

The grand total is $431,433,918.

Ouray County

Bids are being received for driving the Camp Bird's 9000-ft. adit from the mill to the mine. One of the bidders is J. P. Karns, who has devised a tunneling machine of large capacity, and which was tried recently in Utah.

Teller County (Cripple Creek)

The annual number of *The Cripple Creek Times* consists of 52 pages, mostly devoted to mining, edited by Sam W. Vidler, from which the following data are taken:

The December output was $1,352,000 from 83,750 tons of ore. The smelters average was $60 per ton, an increase of $5.

The total production in 1915 was $16,189,727 from 382,897 tons of ore. The largest month was March, with $1,986,493 from 76,618 tons, when the Cresson mine shipped so much rich ore. Its output last year was $1,983,200 from 60,000 tons of ore. The Cripple Creek district has produced $351,764,653 to date.

The approximate outputs last year were as follows:

Mills	Tons.	Value.
Golden Cycle (own mine and custom ore)	407,950	$9,179,650
Portland (Cripple Creek)	211,415	642,179
Portland (Colorado Springs)	128,000	2,600,000
Portland (Stratton's)	66,700	155,284
Stratton's Independence	55,256	169,755
Colburn-Ajax	15,235	105,577
Gaylord	9,700	26,700
Neville-Free Coinage	8,152	28,228
Kavanaugh-Jo Dandy	6,800	13,600
Wild Horse	3,730	15,105
Isabella	1,500	3,000
Calcy	4,917	19,064
Smelters	52,692	2,944,250

Dividends paid by listed corporations were as follows:

Golden Cycle Mining Co.	$3,495,000
Portland Gold Mining Co.	360,000
Vindicator Consolidated Gold Mining Co.	225,000
Elkton Consolidated Mining & Milling Co.	50,000
El Paso Consolidated Gold Mining Co.	50,000
Mary McKinney Mining Co.	26,185
Total	$4,206,185

Dividends of close corporations were as follows:

Cresson Consolidated Mining & Milling Co.	$1,000,000
Stratton's Cripple Creek Ltd. (sale of property, estimated)	500,000
Strong Gold Mining Co. (estimated)	250,000
Stratton's Cripple Creek Mining & Development Co., the Stratton Estate, (estimated)	50,000
Gold King Mining Co.	10,000
Total	$1,810,000
Profits of leasing companies and lessees, closely estimated	$ 500,000
Grand total of dividends and lease profits	$6,516,185

In 10 months the Roosevelt drainage-tunnel was extended 1920 ft.; since August 1 the monthly rate has been 300 ft. The heading is within 250 ft. of the Elkton main shaft. Fifty-two men are employed in charge of C. Fuller. The total subsidence of water was 149 ft. The total water discharged last year was 5,550,000,000 gal., equal to 37,000,000 gal. per vertical foot, according to T. R. Countryman. The water has a temperature of 70° F.

There are now four producing mines on the recently-opened Tenderfoot hill, namely the Ella W., Queen Bess, Black Diamond, and the Hickman lease. Prospects are good.

Mill employees of the Golden Cycle and Portland companies at Colorado Springs have been given an advance of 25c. per day. This applies to those receiving less than $3 per day.

As Colorado went 'dry' on January 1, 30 saloons closed their doors in the district.

On January 10 the Golden Cycle Mining & Reduction Co. paid dividend No. 105, amounting to 2c. per share, equal to $30,000. With this distribution the shareholders will have received a total of $7,338,000.

IDAHO

Shoshone County (Coeur d'Alene)

An extensive deposit of scheelite has been opened in the

Golden Chest mine at Murray, and shipments of rich ore are being made. Fifteen men are working three shifts. Three sacks, worth $675, were stolen last week.

An Ingersoll-Rand compressor of 2000-cu. ft. capacity, costing $11,000, to be driven by a 250-hp. General Electric motor, is being installed at the Red Monarch in Missoula gulch. Ore-cars, pumps, pipes, steel, etc., has also been purchased.

MICHIGAN

The Copper Country

From January 1 to July 1, 1916, the Calumet & Hecla and its subsidiaries will pay all employees a premium of 10% on their monthly wages. Twelve thousand men will be affected, receiving at least $500,000 over the normal amount for the period. This voluntary gift does not bear out the accusations made against these companies during the strike of two years ago.——The Copper Range company, controlling the Baltic, Champion, and Trimountain, will also pay a bonus to employees, amounting to 15%, for January and February. About 3000 men will benefit.

MISSOURI

Jasper County

An indication of the great amount of work done in the zinc-lead region is shown by a comparison of electricity sold by the Empire District Electric and Ozark Power & Water companies during the four weeks ended December 4, 1915, and that period of 1914:

Company.	1915 kilowatt-hours.	1914 kilowatt-hours.
Empire	6,621,830	4,301,710
Ozark	2,946,600	353,100

During this period of 1915 the net increase in load actually connected to the lines, after allowing for disconnections, was 1496½ hp. The power department secured 1815 hp. in new contracts and additions to existing contracts during this period, most of the business being of the latter character.

MONTANA

Beaverhead County

The new owners of the Bannack gold mine, J. H. McClement and F. G. Corning of New York, have paid the first installment of $40,000, out of the sale price of $240,000. About $125,000 has been spent by them in development and a new mill. Ore opened is valued at $1,000,000. Wide stopes have been opened. G. T. Hansen in manager.

Lewis and Clark County

On February 1 the Scratch Gravel Gold Mining Co. will pay 2c. per share, or $20,000, the first monthly. Some excellent ore is ready for the mill all the time.

NEW MEXICO

Grant County

The property of the Savanna Copper Co., in the Burro Mountain district, has been sold for $700,000 cash, to, it is reported, the Burro Mountain Copper Co., a Phelps-Dodge subsidiary.

Other large mining transactions in this State of recent date are the sale of the Carlisle mine, Steeplerock district, for $300,000; the Mogollon Gold & Copper mine, Cooney district, for $100,000; and the Bonney mine at Lordsburg for $25,000.

THE BONNEY MINE, LORDSBURG, NEW MEXICO.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated company in December is as follows:

Ore mined, tons	35,000
Gross extraction	$212,000
Operating expenses	161,000
Net realization	$51,000

An area of 900 acres of copper claims in the Cuprite district, 13 miles south of Goldfield, has been purchased by ex-Senator W. A. Clark of Montana, from Ellsworth Oldt, a pioneer of that district. A good deal of ore has been developed. Work has been started in charge of H. Evans.——The Rea mine, several miles west, was recently sold to large copper interests. Its prospects are also good.

Humboldt County

Since work was started by the Rochester Mines Co. early in 1913, the output by the company and lessees totaled $1,015,345 from 52,282 tons of ore to the end of 1915. Mine openings amount to 18,000 feet.

Supposed barren ground of the Nevada Packard is now showing $52.70 ore; this is in the south drift off the D. adit.

Good results are reported from the Packard North Extension; more men have been started.

During 1915 the Seven Troughs Coalition company produced $416,084 gold and silver from 4509 tons of ore, and paid five dividends amounting to $180,378. Total distributions are $216,192. The ore treated, which came from all parts of the mine, averaged about $93 per ton.

Nye County

Five companies and lessees at Tonopah last week produced 2943 tons of ore worth $201,934. The Tonopah Extension v. West End Consolidated quarrel has gone a step farther. In that the plaintiff wishes the defendant restrained from crosscutting away from the area prescribed in the modified order of Judge Averill on December 7, 1915. The Court was to hear the case on January 7, and in the meantime the defendant was restricted in its work in the disputed ground.

Storey County

The Mexican Gold & Silver Mining Co. has levied an assessment, No. 103, of 10c. per share. The directors state that the last assessment levied on Mexican stock was on December 6, 1910. Since that time the ore discovered on the 2500-ft. level, in what was supposed to be barren ground, has enabled them to pay $171,360 in dividends; to build a modern mill at a cost of over $100,000, and to contribute heavily toward the pumping of the Comstock lode, and toward the present equipment of the North End mines in general. At no time during the past 20 years have the mines at the north end been so admirably equipped and harmoniously managed, and the discovery of the ore in Union and Sierra Nevada, is but additional proof of the possibilities in depth. The discovery of the ore in the Union and Sierra Nevada mines on what is known as the main Comstock or foot-wall fracture has doubly affected the Mexican. In the first place its mill, which has been comparatively idle, now becomes an asset of the first importance, since it is the only efficient and modern plant on the ground; in the second place it opens possibilities in that same fracture to the Mexican, as a large section of the vein in its property on the 2500-ft. level and below has never been explored. This exploration has now begun, and there is, in addition to the great possibilities existing at 2700 ft. and below, in the east vein, equal or even greater possibilities in the main Comstock. The mill is now treating all the ore produced by the Union and Sierra Nevada mines at a good profit but it was necessary to secure large supplies of cyanide and zinc-dust in order to insure continuous operation. On account of the War, these articles had risen greatly in price, and in fact it was with the greatest difficulty that they were obtained at all in sufficient quantities. To defray the expenses of exploration and mill equipment, therefore, the present management levies its first assessment, and can only assure the stockholders that every effort is being made to uncover ore, and that of the ultimate success of these efforts the management has no reason to doubt.

OREGON

Baker County

Work has been resumed at the Iron Dyke copper mine at Homestead, after years of idleness. The lessees are shipping two cars of ore a day to Huntington, then to Colorado. They are erecting a bunk and boarding-house for 150 men.

The Cornucopia company has a number of men developing its Wilson claims.

The revival along the Snake river is of interest.

SOUTH DAKOTA

Lawrence County

The Wasp No. 2 mill is treating up to 175 tons of gold ore per day, or 30% of capacity, but better ore has been opened lately. The new tungsten concentrator is at work. The last shipment of this ore was 26 tons worth $54,000, instead of $48,000, as previously published.

UTAH

Juab County

Shipments from the Tintic district last year totaled 6458 cars, the principal contributors being as follows:

Chief Consolidated, 1109, Iron Blossom, 1067, Centennial Eureka, 1005, Sioux mill dump, 659, Eagle & Blue Bell, 563, Mammoth, 523; Gemini, 279, Grand Central, 209, Dragon Consolidated, 181; May Day, 130, Gold Chain, 105; and Lower Mammoth, 97. There were 27 other producers ranging from 79 to 1 car.

The new plant of the Tintic Milling Co. will be completed in a few weeks.

The low-grade dump at the May Day, 50,000 tons, is to be treated by the Utah Minerals Concentrating Co., whose plant is kept busy on ore from various mines of the district. Part of this dump was cyanided.

Salt Lake County

The new copper shoot in the Bingham-New Haven section of the Utah Metal property is 400 ft. lower than any ore found previously. On the 850-ft. level two feet assays 8% copper and 10.5 oz. silver per ton. The mill is treating 140 tons a day. Earnings in December were $50,000.

During the year ended August 31, 1915, the Utah Apex company's revenue was $848,821, of which $271,497 was profit. Owing to peculiar conditions large ore reserves cannot be opened, so continuous development is necessary. A process is being tried to separate the lead and zinc.

The Sells mine in the Little Cottonwood district sent out its first car of ore from the recent development. It settled for $41.76 per ton. The moisture was 21 per cent.

Summit County

Owing to the cold weather and shortage of water, the Big Four mill, treating tailing below Park City, is closed. The Daly West mill may also be stopped for a time.

The Snake Creek tunnel was advanced 341 ft. in December, and 3273 ft. in 10 months. The last 50 ft. was in diorite. The flow of water was 19 second-feet on January 2, nearly double that of a year ago. The heading is in 13,721 feet.

WASHINGTON

Stevens County

A 100-ton electro-chemical plant is to be erected by the Bimetallic Milling Co. at Turk, 25 miles west of Springdale. E. O. Weston of Spokane is president of the concern. Contracts have already been made for treatment of ore from several mines. The Fields' process is to be used. The plant will be either driven by steam or gas engines.

Two zinc furnaces are to be erected at the Northport smelter, in addition to the copper and lead furnaces. Zinc ore from the Coeur d'Alene of Idaho will probably supply the new plant.

By the installation of an Oliver filter the United Copper Co. at Chewelah expects to reduce expenses by $2000 per month.

CANADA

Ontario

The mining industry of this Province in 1915 is briefly discussed by Thos. W. Gibson in the January Bulletin of the Canadian Mining Institute. He estimates the production as follows:

Metal.	1915.	1914.
Copper	$2,700,000	$2,081,332
Gold	8,000,000	5,529,767
Nickel	7,200,000	5,109,088
Silver	10,750,000	12,795,214

Copper and nickel were in great demand, hence the increase; the Porcupine district is responsible for the larger gold output; low prices affected silver production at Cobalt.

MEXICO

According to Wilbert L. Bonney, U. S. Consul at San Luis Potosi, for the first time in months there appears to be a possibility of a gradual and part resumption of mining and ore treatment in the San Luis Potosi district. The operation of these industries depends on so many diverse factors that it is impossible to set any date for resumption, but conditions are now more favorable and the problems of operation are being taken up for solution. The mines cannot work until the smelters can take care of their product, and the smelters require regular transportation and the use of 60 to 80 cars per day continually for their operations. It is further necessary to assemble foreign employees from various parts of the United States and to have a stock on hand and a continuous inflow of supplies, such as dynamite, cyanide, coke, oil, chemicals, and repair parts that have become entirely exhausted. For the operation of the lead smelter it is necessary to purchase lead, copper, limestone, and other ores for making the necessary combinations, and some of these ingredients must be brought from distant parts.

For the financing of all these operations it is necessary that the product be exported and sold promptly, and in order to avoid an expensive shut-down all the processes must be continuous. San Luis Potosi depends upon the Tampico railway for nearly all of its heavy freight, and that line must be kept open if the lead smelter is to operate. The minimum steamer load of coke arriving at Tampico for the smelter is 3000 tons, or about 150 carloads.

The experience of the smelters has been unfortunate for the last two years, and attempts to operate in other districts have served to discourage the San Luis Potosi companies. The Monterrey smelter No. 3, which has the advantage of proximity to the frontier and to the Coahuila coalfields, attempted to resume in July. After about three weeks, during which stocks on hand were used up, it was found impossible to continue by reason of failure of transportation. The smelting company bought and paid for 25 cars of oil in Tampico, but was able to secure delivery of only 5 cars. In San Luis Potosi the cost of coke and other heavy material by rail from the frontier is prohibitive; they must come by water to Tampico.

In addition to the necessities already named, the smelter must have a constant supply of water in its dams. The 1915 season has been dry, and there is not at present sufficient water for use of the smelter. Considerable local difficulty is experienced on account of new and increased wage demands, and careful negotiation in this respect will be necessary. Difficulties are also experienced by reason of the fluctuation of the paper money in which labor is paid.

In these circumstances individuals operating small mines will find it practicable to begin taking out ore while the large organized companies are discussing the solution of their various problems. The conditions herein described apply to the mining and smelting of silver, lead, copper, antimony, and sulphur.

According to Thomas H. Bevan, U. S. Consul at Tampico, the attention of the oil interests during the week of December 10 centred on the well of the Pan American Oil Co., at Panuco, which was brought in on the first of the month and has been conservatively estimated to have a production of 2000 bbl. per day. Oil was first struck at a depth of 1760 ft., and drilling was immediately suspended.

There has been considerable leasing of oil lands in the southern fields during the past two months. A number of companies that now have production in the Panuco field have taken up leases in the Tuxpam fields where a lighter gravity of oil is found. The Compania Mexicana de Petroleo "El Aguila" S. A., is now making preparations to commence drilling again in the State of San Luis Potosi near Valles. The company drilled three wells in this territory over two years ago, which are the deepest oil wells in Mexico.

PERSONAL

LUTHER WAGONER has gone to Havana, Cuba.

R. B. LAMB, of New York, is at Oatman.

S. J. SPEAK has returned to London from South Africa.

WILLIAM Y. WESTERVELT has returned to New York from Cuba.

RALPH STOKES has been promoted to captain in the Royal Engineers.

T. P. MCNAMARA is superintendent of the Dome mine near Porcupine.

F. DORRION is manager for the Corocoro United Copper mines, Peru.

HARRY JAMES passed through San Francisco on his way from Denver to Honolulu.

K. P. SWENSEN, of the F. W. Horne Co. of Tokyo, returned to Japan on January 8.

A. A. COLE of Cobalt has been nominated for president of the Canadian Mining Institute.

B. M. MCATEE is now foreman in charge of flotation at the Inspiration mine, near Miami, Arizona.

L. W. ORYNSKI is superintendent of the Skidoo Mines Co., California, L. S. PRESTON resigning on December 31.

C. E. GRUNSKY, JR., has been elected secretary-treasurer for the San Francisco section of the American Institute of Mining Engineers.

O. G. ENGELDER, formerly in the geological department of the Calumet & Arizona company at Bisbee is in Rosas, Sardinia, Italy.

L. E. YOUNG, professor of mining in the University of Illinois, has been giving a series of lectures on the 'Economics of Mining' at the University of California.

HOWLAND BANCROFT has just returned to Denver from several months' absence in South America and leaves within a few days to make his headquarters in Chile during the next two years.

ROSWELL H. JOHNSON, Professor of Geology in the University of Pittsburg, attended the second Pan-American Scientific Congress at Washington, D. C., and read a paper upon 'The Conservation of Oil and Gas.'

Associated with WILLIAM J. COX, general manager of the Camp Bird at Ouray, Colorado, are J. B. GLASSER, assistant manager; JOS. H. SCOTT, mine superintendent; and THOMAS H. WOODS, mills superintendent, according to the recently-issued annual report.

EDWIN HIGGINS, mining engineer of the Bureau of Mines, has been appointed Chief Mine Inspector for the Industrial Accident Commission in California, in succession to H. M. WOLFLIN, who has been promoted to the post of Mine Safety Engineer in the Bureau of Mines, with headquarters at Pittsburg.

According to the recently-issued annual report of the Consolidated Mining & Smelting Co. of Canada, operating in British Columbia, the present staff is as follows: R. H. STEWART, general manager; S. G. BLAYLOCK, assistant general manager; T. W. BINGAY, comptroller; JAMES BUCHANAN, superintendent of smelter; M. H. SULLIVAN, assistant superintendent of smelter; J. F. MILLER, superintendent of refinery; F. W. GUERNSEY, in charge of zinc experimental work; C. H. MCDOUGALL, engineer in charge of construction at smelter; M. E. PURCELL, superintendent Centre Star group of mines; E. G. MONTGOMERY, assistant superintendent; F. S. PETERS, superintendent Le Roi mine; J. K. CRAM, St. Eugene and Sullivan mines; W. M. ARCHIBALD, mining engineer in charge of Ainsworth and Slocan properties.

THE METAL MARKET

METAL PRICES

San Francisco, January 13

	Cents per pound
Antimony	18
Electrolytic copper	25
Pig lead	6.15—7.20
Quicksilver (per flask)	$165
Spelter	20
Tin	45
Zinc-dust 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, January 13.

Antimony stronger, 50% product, per unit $2.25
Chrome 40% and over, f.o.b. cars California, per ton.....15—18
Magnesite, crude, according to quality and quantity, per ton, f.o.b. .....7.50—10
Magnesite plastic, no iron and lime, calcined, per ton.... 50
Magnesite refractory, up to 7% iron, calcined, per ton...30—40
Manganese 50% metal, 8% silica, per ton, f.o.b. cars, S. F. 12
Tungsten minimum 65% WO_3 per unit for spot.....10—50

The following prices were paid for one lot of tungsten concentrate at Boulder, Colorado, last week: 60.9%, $17.50; 49.7%, $14.50; 42.1%, $12.40; 28.6%, $35, and 17.3%, $29 per unit.

New York, January 7.

Antimony, per unit	$2.00 — 2.10
Manganese, 80% metal, f.o.b. New York, per ton....	70.00
Molybdenite, 95%, per lb.	1.50
Tungsten, according to position	40.00—50.00

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 13.—Copper producers are firm, resellers are cutting, lead is easier and unsettled; zinc is quiet but firm.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Jan.	6	.56.62	Dec. 1 .....56.27
"	7	.56.62	" 8 .....55.51

Exports during the week ended December 25 totaled 9,861,113 lb., valued at $1,907,520. England took 5,477,158 lb., France, 2,005,538 lb., and Italy, 1,205,332 lb. Imports amounted to 10,181,219 lb., worth $1,821,212. Chile sent 5,896,627 lb., and Peru, 3,178,204 pounds.

The A. S. & R. Co. in 1915 had a balance of 13% for the common stock. Calumet & Arizona made $10 per share net last year, and Ray $3.10.

The Tennessee Copper Co.'s acid plant is closed indefinitely. This will affect earnings considerably.

LEAD

Lead is quoted in cents per pound, New York delivery.

Tin is quiet at 41 cents.

Eastern Metal Market

New York, January 7.

As might be expected after the recent heavy purchases, domestic inquiry for copper is quieter, but the export inquiry continues very heavy, and probably will support the market for a time at its present level of 23 to 24c. Zinc has not moved in sympathy with copper, but its quotations are fairly well maintained. Lead is extremely strong, three advances having been announced within the week, all of which is principally due to foreign activity. Tin has had its ups and downs because of unconfirmed rumors. Antimony is scarcer than ever for spot delivery, and is quoted up to 43c. Aluminum is easier.

The prospects before the iron and steel trade are unprecedented. Heavy specifications continued to come out to the very end of 1915, and began promptly again with the first working day of the new year. Steel capacity in 1916 will be increased 4,265,000 tons by new furnaces now under construction or planned. The pig-iron output in December made a further gain, although the season is usually one of slower operations; the month's production was 3,203,322 tons, or 103,333 tons per day. Pig-iron is now being made at the rate of 38,000,000 tons per year. The 'fly in the ointment' is labor trouble, which has broken out virulently at Youngstown, Ohio, while farther East there are minor strikes at steel plants. The Steel Corporation, and most of the independents, have voluntarily agreed to increase the wages of common labor 10%, and of other labor proportionately.

COPPER

Both here and in London copper shows great strength, and in regard to prices both markets seem to have got beyond control. The New York quotation for prompt electrolytic, January 6, was 23.50c., cash, while the quotation in London on that day was £114. Lake was nominal on the same day at the same price. The features of the present situation are these: electrolytic producers are well sold up to April, while makers of Lake are booked until June; spot electrolytic is scarce and current trading is principally in positions one or two months off; consumers are well covered as a result of their recent activity, but there is a great foreign demand which has not yet been satisfied. As a matter of fact, it is the foreign demand that is supporting the market. A representative of one of the large copper companies said early this week that export inquiry was pouring in on his company, but that it had not, up to that time, resulted in a proportionate amount of actual business. In view of their sold-up condition, many of the producers would be pleased if there came a general lull in buying, for they have taken on heavy commitments to supply, not what they have, but what they must make, and some are becoming a little uneasy. The entire atmosphere is most bullish, and predictions of copper at 25c. or higher, are freely made. As the quotations go up consumers become more frightened and more inclined to buy ahead. Exports in December reached the comparatively large total of 32,936 tons, making the month the record one of the year, the largest previous monthly total having been 30,148 tons in March. The base price of sheet copper was advanced this week to 30c. The summary of December exports shows that the United Kingdom received 8590 tons; France, 14,501 tons; Holland, 398 tons; Italy, 5154 tons; Denmark, 300 tons; Sweden, 2867 tons; Russia, 400 tons; and others, 726 tons. Electrolytic at London is quoted at £114.

ZINC

In strange contrast with copper, zinc has been quiet, almost dull, and continuously so for several days. Quotations have changed but little, but that little has been downward, the New York quotation during the greater part of this week standing at 17.30c., for prompt delivery metal. Today the New York quotation is 17.50c. Practically the only interest shown has been in spot or nearby, and the indifference of the consumers has brought out some pressure to sell. The report of the U. S. Geological Survey on January 3 stated that stocks in producers' hands on December 15, 1915, amounted to 20,758 tons, against 5884 tons on June 30. It had the effect of making some sellers a little more ready to part with their holdings, and business was done the following day at or near 17.15c., St. Louis, for spot, 17c. for January, 16.15c. for February, and 15.50c. for March. Exports in December totaled 6103 tons.

LEAD

The A. S. & R. Co. advanced its New York quotation on December 31 to 5.50c., an increase of $2 per ton; on January 4, it announced another advance of $5 per ton, or to 5.75c., New York, and on the 7th its quotation went to 5.90c., New York. All of these were expected. A great quantity of lead has been purchased in the past week or ten days, and export requirements promise a continuance of demand. Russia has been a very heavy buyer, both directly and through agents, while others, both at home and abroad, have been eager buyers also. To a considerable extent the situation is much the same as exists in copper, though not so acute. The December exports totaled 6775 tons. The London market is strong at £31 15s., an advance of £2 15s. in about 10 days.

TIN

This metal has been most unsettled. On various days there has been a fair amount of business in tin afloat, or for shipment from the Far East, but prompt and nearby has been scarce and to a large extent inactive. Considerable excitement was created on January 3 by a report that a Japanese steamer, the *Kenkon Maru*, en route from the Straits to London, had been sunk in the Mediterranean with a large quantity of tin, but up to the present time it has not been entirely cleared up as to whether the vessel lost really had tin among its cargo. It appears that there are several ships bearing the name Kenkon Maru. In the excitement occasioned by the report, which had it that probably 1000 tons of tin had been lost, the spot quotation advanced 2c., or from 40.50 to 42.50c. On the 4th the furor had not subsided, and spot tin went to 45c.; on the 5th the quotation dropped to 44.75c., and the 6th to 42.50c. Deliveries into consumption in December reached the excellent total of 5200 tons. Total deliveries in 1915 were 47,835 tons, against 41,700 tons in 1914. In stock and landing at the end of the month was 1371 tons, and afloat there was 8125 tons. The total visible supply on December 31, 1915, was 16,216 tons, against 13,396 tons on the same date of 1914.

ALUMINUM

No. 1 virgin aluminum, 98 to 99% pure, is quoted at 54 to 56c., in a dull and uninteresting market.

ANTIMONY

The supply of spot antimony is so limited that the quotation is nominal. The price quoted is 43c., duty paid, for Chinese or Japanese grades. There are some arrivals in prospect, but they are stated to have been sold and will not relieve the situation.

The U. S. Geological Survey and the Mint report that the gold output of the country in 1915, including Alaska, the Philippines, and Porto Rico, was $98,891,100, an increase of $4,359,300. Save one, all States showed advances.

The silver output was 67,485,600 oz. averaging 51c. per oz. Montana was probably first, having overtaken Nevada.

Metal Production in 1915

LEAD

The lead industry in 1915 made good gains in output, both in mining and smelting. The lead content of ore mined in the United States was apparently over 600,000 short tons, compared with 522,864 tons in 1914, an increase of 15%. With the higher prices prevailing the percentage of increase in value of the 1915 output was even greater when compared with other years. The following estimates have been compiled by C. E. Siebenthal from reports to the Survey by all the lead refineries and soft-lead smelters in operation during the year, except two smelters in the Joplin district, for which estimates have been made.

The production of refined lead, desilverized and soft, from domestic and foreign ores in 1915 was approximately 565,000 tons, worth at the average New York price $53,110,000, compared with 542,122 tons, worth $42,285,500, in 1914, and with 462,460 tons in 1913. The figures for 1915 do not include an estimated output of 20,550 tons of antimonial-lead, worth $1,886,000, against 16,667 tons in 1914 and 16,665 tons in 1913. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 306,682 tons, against 311,069 tons in 1914 and 250,578 tons in 1913; and desilverized lead of foreign origin at 48,318 tons, compared with 29,328 tons in 1914 and 50,582 tons in 1913. The production of soft lead, mainly from Mississippi Valley ores, is estimated at 210,000 tons, compared with 201,725 tons in 1911 and 161,300 tons in 1913. The total production of lead, desilverized and soft, from domestic ores, was thus about 516,682 tons, compared with 512,794 tons in 1914.

Imports of lead are estimated at 9625 tons of lead in ore, valued at $653,000; 50,825 tons of lead in base bullion, valued at $3,496,000; and 400 tons of refined and old lead, valued at $28,000—a total of 60,850 tons, valued at $4,177,000, compared with 28,338 tons in 1914. Of the imports in 1915 about 58,000 tons came from Mexico, against 23,141 tons in 1914. These imports from Mexico are to be compared with an average of over 100,000 tons before the civil strife in that country. The remaining imports of lead came mostly from Chile.

Exports of lead of foreign origin smelted or refined in the United States again show an increase, being estimated at 43,000 tons, against 31,051 tons in 1914 and 54,301 tons in 1913. For the last two years, on the other hand, notable quantities of domestic lead have been exported to Europe, and the total for 1915 is estimated at 76,000 tons, valued at $6,650,000, compared to 58,722 tons, valued at $4,501,674 in 1914.

The average New York price for the year was 4.7 cents a pound, compared with 3.9 cents in 1914 and 4.4 cents in 1913.

ZINC

Both the zinc smelting and the zinc mining industries of the United States enjoyed a year of unparalleled prosperity in 1915. According to the best information obtainable at this time the recoverable zinc-content of zinc ores mined was over 560,000 short tons, compared with 407,000 tons in 1914 and 418,000 tons in 1913. With a continuance of high price for spelter during 1916 the output will be greatly augmented, for the very high prices did not begin until April and May and it was naturally some time before much additional zinc mining could get under way. Production during the last quarter of the year was at a much higher rate than during the first quarter.

There was a large increase in smelting capacity during the last half of the year, the total number of retorts at the end of the year being 154,898, compared with 130,642 at the midyear, and with 113,914 at the beginning. In addition, 20,758 retorts were under construction or planned.

It seems certain that the zinc-reduction capacity of the United States will soon be equal to every conceivable call upon it.

The following figures have been compiled without change by C. E. Siebenthal, from reports furnished by all operating smelters of zinc ores except one, showing their output for the first 11 months of the year and their estimated production for December.

The production of primary spelter from domestic ore in 1915 is estimated at 460,000 short tons, and from foreign ore at 30,000 tons, a total of 490,000 tons, worth at the average St. Louis price, $139,160,000, compared to a total of 353,049 tons in 1914, worth $36,010,998, and made up 343,418 tons of domestic origin, and 9631 tons of foreign origin. This was a gain of 137,000 tons and of more than $103,000,000 in value. As noted above, however, the gain in value was considerably more than this amount. The production of spelter from both domestic and foreign ores, apportioned according to the States in which it was smelted, by six-months periods, was as follows, in tons:

State.	1914 First half.	1914 Second half.	1915 First half.	1915 Second half.
Illinois	62,062	65,884	74,982	85,348
Kansas	23,737	20,773	35,247	65,398
Oklahoma	45,443	45,924	51,172	57,532
Other States	43,816	45,410	55,131	65,190
Total	175,058	177,991	216,532	273,468
Yearly total	353,049		490,000	

The zinc-smelting capacity was as follows:

State.	Total retorts end of 1915.	Retorts to be added in 1916.
Illinois	38,424	4,840
Kansas	40,366	....
Oklahoma	39,212	7,710
Other States	36,896	8,208
Total	154,898	20,758

Imports of zinc ore in 1915 were approximately 135,000 short tons, containing about 48,000 tons of zinc, and worth about $4,000,000, compared with 31,962 tons of ore, containing 12,132 tons of zinc, in 1914. The zinc imports for the first 10 months of 1915 were as follows, in tons:

Country.	Ore.	Zinc-content.	Value.
Australia	45,972	16,700	$1,273,131
Canada	8,907	3,494	118,636
China and Japan	7,572	3,213	193,604
Italy	5,312	2,125	153,388
Mexico	49,694	14,521	1,610,270

Exports of spelter and sheets made from domestic ore are estimated at 115,000 tons, worth $25,530,000, compared with 64,807 tons in 1914. Exports of spelter made from foreign ore are estimated at 13,000 tons, valued at $2,250,000, compared with 5580 tons in 1914. Exports of brass are estimated at 33,500 tons, valued at $12,200,000, compared with 3558 tons in 1914. Manufactures of brass were exported to the value of about $30,000,000, compared with $3,756,888 in 1914.

Exports of domestic zinc ore were about 900 short tons, valued at $45,000, compared with 11,110 tons in 1914. Foreign zinc ore containing 609 tons of zinc and valued at $24,270 was re-exported. Imports of spelter (probably mostly scrap) are

estimated at 863 short tons, valued at about $122,358, compared with 880 tons in 1914.

The apparent domestic consumption of spelter in 1915 may be computed as follows: The sum of the stock on hand at smelters at the beginning of the year, 20,095 tons, plus the imports, 863 tons, and the production, 490,000 tons, gives the total available supply—511,000 tons. From this are to be subtracted the exports of domestic spelter, 115,000 tons, the exports of foreign spelter, 13,000 tons, the exports under drawback, 255 tons, and the stock on hand at smelters at the end of the year (to be exact, on December 15), 20,758 tons, or a total of 149,000 tons, leaving a balance of 362,000 tons as the apparent domestic consumption. This calculation takes no account of the stocks of spelter held by dealers or consumers. On comparing the consumption in 1915 with the 299,130 tons consumed in 1914, the 295,370 tons in 1913, and the 340,341 tons in 1912, it appears that the indicated consumption is not large when the larger exports of brass and manufactures of brass are considered.

The average price for the year of prime western spelter at St. Louis was 14.2 cents per pound.

COMPANY REPORTS

BRADEN COPPER CO.

This company's report covers the year ended August 31, 1915, and is mostly taken up by the report of the consulting engineer, Pope Yeatman, who recommended that the capacity of the plant be increased to 10,000 tons of ore per day, at a cost of $7,500,000. The mill can treat 4500 tons at present.

The property has an area of 2362 acres. The labor situation has greatly improved from several causes.

A great deal of work has been done in developing the orebodies, and in preparing them for mining. The crater, about two miles in circumference, around which the ore occurs, has been completely circled, and in this circle have been proved five distinct orebodies, namely, the Fortuna, Regimiento No. 2, Teniente, Centinela, and Bornite. Stoping operations are now being carried on in Fortuna, Centinela, and Bornite, mining on the Fortuna largely predominating. No work has yet been done on the Regimiento No. 2 to prepare it for stoping, but on the Teniente, the largest and richest deposit, No. 1 and 3 levels are being put in shape to supply the large tonnages of ore to be extracted, and level C is being prepared for active stoping. Strictly speaking, the five orebodies are the richer or commercially profitable portions of the deposit completely surrounding the crater. In July, 1911, reserves amounted to 10,074,616 tons, averaging 2.7% copper; on January 1, 1915, the quantity of developed, probable and possible ore was 113,694,880 tons of 2.5% ore. Further work assures a greatly increased tonnage. On Teniente No. 1 level, the Teniente shoot is 4800 ft. long, with an average width of 300 ft., and a depth of 840 ft. The method of mining is like that at the Ray in Arizona, namely, caving and shrinkage stoping. Ore is taken out of the mine by adits, no shafts being necessary for this. Up to October 31, 1915, the ore mined totaled 3,204,484 tons, averaging 2.25%. Openings to April 1, 1915, amounted to 198,970 ft., nearly 38 miles.

The electric railway between mine and mill is working well. Extraction in the mill is improving, being 77%, with 80% expected. The sulphuric-acid plant supplying acid for flotation is making 20 tons a day.

Smelting has been the cause of much difficulty and experimenting. The blast-furnaces and converters gave good results under the conditions.

The hydro-electric plant has now a capacity of four 2000-kw. Pelton wheels and generators.

During the year under review 1,106,420 tons of ore was treated, assaying 2.09% copper, yielding 16,367 tons of metal, at an average cost of 8.78c. per pound. October costs were 7.36c. Future charges are estimated at $1.85 per ton of ore, and 6.5c. per pound of copper.

The profit and loss account shows revenue of $4,126,040 from metal, $1,258,170 profit, $806,676 for interest, and a balance of $537,535. S. S. Sorensen is general manager in Chile.

CAMP BIRD, LIMITED

This company's report deals with the year ended June 30, 1915. The directors' statement shows that of the available profit of £123,291, £100,476 was paid in dividends. The balance carried forward is £6590. From April 30, 1903, to June 30, 1915, the output was 795,129 tons of ore yielding £4,615,389, with a profit of £2,885,418. The revenue was $27.86 and expenditure $10.44 per ton during this period. The company holds considerable interest in the Imogene Basin Gold Mines Co., Santa Gertrudis, Messina (Transvaal) Development Co., and the Central American Goldfields Syndicate.

The general manager at Ouray, Colorado, William J. Cox, reported as follows: Ore was derived from seven levels of the mine. Development was confined mostly to the ground reached through No. 3 shaft. Reserves are estimated at 14,800 tons of broken, and 1100 tons of unbroken ore, containing a profit of $275,000.

The mills treated 32,313 tons of ore, yielding $952,288, an average of $29.47 per ton. This is an increase of $151,209 compared with the previous period. The combined gold and silver recovery was 94.31%. Of the total value, amalgamation gave 58.48%, concentration, 36.59%, and cyanidation, 4.93%. The cyanide-plant treated 20,655 tons of tailing. The profit at the mine was $583,700.

SANTA GERTRUDIS CO., LTD.

This company operates in the State of Hidalgo, Mexico, and the report covers the year ended June 30, 1915. The general manager, Hugh Rose, and advisory engineer, William J. Cox, both made reports.

Development amounted to 15,838 ft., the last half of the term being at double the rate of the first half. An important orebody was opened on No. 1 and 3 levels. Its probable dimensions are 380 ft. long and 10 ft. wide, assaying $7.92 per ton. Not much was done on No. 20 level. Development of the hanging-wall bodies was satisfactory. Reserves are estimated as 1,287,000 tons, containing 81,086 oz. gold, and 16,217,296 oz. silver.

The rate of production varied from 85 to 40% of normal capacity, with an average of 52.7%. The local revolution and European war were responsible for this. The mill treated 221,596 tons of ore, worth $6.28 per ton, with 90.31% extraction. The bullion contained 10,727 oz. gold and 2,000,856 oz. silver. The profit was $139,500. From the previous year there was a balance of $625,000. This made $764,500 available, of which $360,000 was paid in dividends.

CHAMPION REEF GOLD MINING CO. OF INDIA, LTD.

This company operates one of the world's great mines, situated in the Kolar district, State of Mysore, India. The year ended September 30, 1915 with a yield of 140,895 oz. gold from 211,368 tons of ore, and $720,000 in dividends. The total to date is 3,607,487 tons, 3,006,454 oz., and $20,650,000 respectively. The superintendent, H. J. Gifford, reported a number of interesting results in the mine and plants. Reserves amount to 495,015 tons, an increase of 17,631 tons. Between Glen and Garland shafts, drifts have been driven 2000 ft. on the shoot from No. 43 to 46 level. Development totaled 15,111 ft. (From 91 to 103 machine-drills were operated.) Some interesting work was done in the cyanide-plants on current and old tailing. A total of 6620 people were employed, 131 being Europeans, and 102 Eurasians.

BOOK REVIEWS

The Mechanical Engineers' Pocket Book. By William Kent. Ninth edition, thoroughly revised with the assistance of R. T. Kent. P. 1,526. Ill., index. John Wiley & Sons, Inc., 1916. For sale by the Mining and Scientific Press. Price, $5.

Kent needs no introduction to engineers and students; the work is always consulted, the appearance of a new edition (the last was in 1910) will be welcomed. There have been many changes and advances in engineering standards and practice during five years, this necessitated changing over 100 pages of the last edition, and an addition of over 150 pages of new matter. Many subjects previously discussed at length have been condensed. Materials, mechanics, blowers, heating and ventilation, fuel, steam-boilers and engines, and steam-turbines have been extensively revised. Machine-shop practice received considerable attention. Electrical engineering will be found up to date. A number of new tables are given. Internal-combustion engines are well treated. The variety of subjects included is too great to detail; they range from air to zinc.

Inorganic Chemistry. Edited by J. Newton Friend. Vol. VIII. 'The Halogens and Their Allies,' by Geoffrey Martin and E. A. Dancaster. P. 337. Ill., index. Charles Griffin & Co., London. J. B. Lippincott Co., Philadelphia, 1915. For sale by the Mining and Scientific Press. Price, $3.

The editor of this work states that the science of chemistry may be divided roughly into organic, physical, inorganic, and analytical branches. No single text-book can contain a thorough treatment of any one of these branches, therefore a series of works covering certain sections of chemistry are better. The work under review has been prepared from a scheme of periodic classifications with slight alterations. The elements of the seventh group of the periodic table (Mendeléeff's law), comprising the halogens and manganese together with those of their compounds, are discussed from a chemical and physical point of view. The elements fluorine, chlorine, bromine, and iodine form a natural group of closely allied bodies known as 'the halogens.' Manganese is quite dissimilar in its properties. The halogens are of great interest to the chemist, and enormous industries have been developed in their manufacture.

Metallurgy of Gold. By Sir Thomas K. Rose. Sixth Edition. P. 601. Ill., plans, index. Charles Griffin & Co., London; J. B. Lippincott Co., Philadelphia, 1915. For sale by the Mining and Scientific Press. Price $6.50.

This is the revised and enlarged edition of a standard work. 'Rose on gold' needs no introduction to our readers. It will be noted that since the date of the previous edition, in 1905, the author has been knighted, in recognition of his scientific work as chemist of the Mint. He is now the president of the Institution of Mining and Metallurgy. Both of these marks of distinction indicate that he is a prophet not without honor in his own country. It is also manifest, from the world-wide distribution of his treatise on the metallurgy of gold, that his exposition of a great subject is appreciated far outside the confines of the British Isles. Indeed, he has won much more than a prefix to his name.

The edition of 1905 was issued at a time when notable changes were taking place in the treatment of gold and silver ores; these changes were mechanical, rather than chemical, and they have continued during the decade since. Hence a new addition was amply warranted. The work has undergone no sham revision; it has been increased by 68 pages; most of the chapters have been re-written, and the contents as a whole have been so re-arranged as to constitute a new book. In the chapter on the physical properties of gold, the information concerning the spark spectra and the position of the metal in the periodic classification are new, so is that on vapor pressure. Crystallization in ingots likewise is discussed on the basis of recent investigations. The gold alloys are now described in a separate chapter of 35 pages, all of them highly interesting. The chemistry and occurrence of gold in nature constitute two chapters of particular interest to mining engineers, and the value of them is heightened by a scholarly bibliography. The two chapters on placer operations are a summary of current knowledge and are remarkable not so much for originality of observation as for concentration of information from a great variety of sources. The same may be said of the author's treatment of amalgamation and the crushing machinery associated with that ancient method of gold extraction. Tube-mills and their linings come under the heading of 'Fine Grinding,' which is discussed admirably. The chapter on 'Concentration' is noteworthy for containing only 10 lines on flotation, undoubtedly the most remarkable process of concentration as yet devised. In the next edition of this book we shall expect a large and deeply interesting chapter on this branch of the subject. But we find that this seriatim treatment of the various chapters will lengthen this review beyond reasonable limits; so we skip some parts. In 'Chlorination,' Sir Thomas returns to an old love, for he was metallurgist in a chlorination plant near Denver in 1887. The 'chemistry of the cyanide process' is worthy of the Chemist of the Mint. Next the cyanide process itself is given adequate treatment, and immediately afterward the author stands on his hearth-rug, as it were, while he writes on the refining and parting of gold bullion. Then come chapters on the assay of gold ores and of bullion, followed by a short chapter of statistics, closing with a bibliography. This book represents the conscientious labor of a keen scholar and a practical metallurgist. It does credit to its well known publisher and confirms the repuation of its distingulshed author.—T. A. R.

Text-Book of Geology. Parts I and II. By Louis V. Pirsson, and Charles Schuchert respectively. Complete in one volume. P. 1051. Ill., plates, map, index. John Wiley & Sons, Inc, 1915. For sale by the Mining and Scientific Press. Price, $4

This text-book has been compiled for use in technical schools and colleges by men of wide practical experience in their respective branches of the science and intimate knowledge of the requirements of the student to prepare him for more advanced study. It presents in connected, though elaborated form, the lectures given by the authors on physical and historical geology at the Sheffield Scientific School of Yale University. It is a welcome, instructive, and valuable addition to technical literature, and will supplant the more voluminous text-books of other writers, in that it gives in well balanced form, all the essentials of a comprehensive elementary knowledge of geology. The interest of the reader or student is maintained by the lucid description and logical sequence of contributory factors to the 'make' of the earth as known today. A discussion of the natural forces which find topographic expression in the earth's crust is augmented by the chemical and physical analysis of the structure developed. Economic geology receives only passing comment in comparison with the number of pages devoted to physiography and palæontology; but the study of ore deposits is a more advanced course.

The text is profusely illustrated with excellent photographs from the field, and descriptive drawings. This is commendable, as it enlivens interest and clarifies what might otherwise be more or less ambiguous statement, although in casual criticism the reviewer would question the advisability of inserting photographs of the great masters of geological and biological science, with pictures of fossils of past geologic ages. Adam Sedgwick, at the age of forty-seven, does not look well with the Ordovician graptolites, nor will the student appreciate the fine features of Huxley, when standing on the shoals of the evolutionary theory before plunging into the depths of palæontological record. Generally the work is excellent.—F. H. P.

EDITORIAL

T. A. RICKARD, Editor

OUR readers must not assume that we had no photographs of the late Mrs. Everson. We have them still.

COPPER has been sold ahead at New York to the extent of the first half of the current year's production.

IN a recent issue we mentioned the new explosive ammonal, made from aluminum dust and ammonium nitrate. We publish this week a timely article on this new use for aluminum, written by Mr. G. H. Clevenger, Professor of Metallurgy in Stanford University.

PASSAGE of the mineral-land leasing bill through the House of Representatives presages the correction of an injury done to oil-operators in California by the withdrawal of public lands under the Taft administration. Approval by the Senate is assured.

WE publish a letter from Mr. F. C. Brown, the inventor of the Pachuca tank, which is more correctly called the Brown agitator. We divulge no secret when we mention the fact that Mr. Brown, instead of trying to collect an irritating royalty from users of his invention, has had the good sense to ask only for a reasonable lump payment based on tank capacity. We are glad to add that his tactful treatment of the problem of getting some recompense for his valuable invention has been frankly recognized by mine operators in this country.

GREAT MINES die slowly. The Camp Bird, in Colorado, has been described as 'exhausted' for three years successively. Last year the company's report said that the reserve remaining would still yield a profit of $307,600; now it is stated that during the past year a profit of $566,500 was won, or $258,900 more than the estimate made the year before; and yet the ore left on June 30 last is expected to yield about $275,000 more. Since then we have heard news of further promising developments, so we shall refuse to consider the mine even moribund.

BOSTON appears to be in danger of losing prestige as a mining centre. Several companies managed from Boston have been listed recently on the New York Stock Exchange. Among them we may mention the Butte & Superior and American Zinc, which are to be followed by the Old Dominion and United States Smelting companies. It is suggested that the reason for the decrease of share activity at Boston is the meagreness of the information vouchsafed to shareholders. In that regard the New York companies are not pre-eminent. Annual or semi-annual reports are of no consequence from the speculator's standpoint. They are too infrequent. To the insiders belongs the game, so long as shareholders are like "dumb driven cattle."

REMARKABLY good metallurgical work is being done by the technical men on the staff of the Sulphide Corporation, which owns the Central mine at Broken Hill, in Australia. At the recent annual meeting of the company it was stated that the recovery of silver was 90.6%, of lead 93.7%, and of zinc 92.8%. The operations include wet concentration, flotation, and smelting. Our compliments to Mr. Charles F. Courtney, the general manager, and to Messrs. James Hebbard and H. A. Evans, the superintendents of works.

ADVICES from Yokohama indicate that the mining industry of Japan has been favored by the War. The exploitation of precious-metal deposits has been increased considerably. Exports of copper are being made to England and Russia. The mining of zinc has been stimulated, and zinc ore from China is being imported for treatment at Japanese smelters. When the War ends, it is likely that Japan will produce a supply of zinc sufficient for the domestic consumption. Lead ore is being imported from Australia. We publish an excerpt from a Japanese official report.

WAR is not often akin to humor, so that the following story will be forgiven. When hostilities began some of the people at Johannesburg wanted to help the cause that they favored. Mayor Dalrymple of the Anglo-French group presented the Chamber of Mines with a plan to equip a contingent to be sent to the front at the expense of the mines. This scheme was popular locally and would have been put through if some of the German directors and shareholders in London, Johannesburg, and elsewhere had not kicked against it. A counter-suggestion was made that a hospital ship be substituted for fighting men, "as this would be fairer to the enemy shareholders"! So a hospital ship it was; but Sir Joseph Robinson, an old curmudgeon not particularly popular in the financial set, because of his predilection for playing a lone hand, sent his contribution of £5000 direct to General Botha to be used for fighting purposes.

ON June 26, 1915, we published an article on the Altai mining region in Siberia by Mr. H. W. Turner. It seemed worth while to draw attention to the introduction of fresh capital and modern methods to a part of the world that offers an inviting field to Anglo-American

enterprise. So far the most important work has been done by the Russo-Asiatic Corporation, although the Russian Mining Corporation has played a good second. As regards the former, we note from the information given at the company's recent annual meeting in London that the ore already proved amounts to 3,171,000 tons, averaging 7.8% lead, 11% zinc, 0.61 oz. gold, and 4.1 oz. silver, with 0.8% copper, from which a profit of $50,000,000 is expected. Mr. H. H. Knox, of New York, made the underlying estimate. Exploratory diamond drilling is still in progress. A railway has been built from the Irtish river to the Ekibastus coalfield, belonging to the Corporation, and another railway is just being completed from the same river to the mines. A zinc-lead concentration plant is being erected at the Ridder mine and a zinc smelter at Ekibastus, so that the enterprise will reach a highly productive stage at an early date. The technical work is in the hands of one Russian and three American engineers, namely, Messrs. A. P. Ivanoff, R. Gilman Brown, Thomas J. Jones, and Deane P. Mitchell. The Russian government is proving most sympathetic and the Corporation has made systematic provision for the comfort of its work-people, including the building of churches, schools, and clubs. Altogether this promises to be the nucleus of a highly organized and most profitable undertaking.

IN another paragraph we refer to the longevity of the Camp Bird mine. We learn now, from London, that it is the intention of the company, acting on the advice of Mr. John A. Agnew, to proceed with systematic exploration in depth by means of a low-level adit. This adit, which is to be 10,700 feet long, is to strike the lode 450 feet deeper than any existing workings and 800 feet below the main ore-bearing ground. The choice lay between the driving of this adit and the sinking of No. 3 shaft, after it had been supplied with a heavier equipment, and the pumping of a heavy inflow of water. The method chosen for testing the question of deeper persistence is undoubtedly the wiser of the two alternatives. What the chances are of discovering valuable orebodies is another matter. Mr. Agnew is an engineer of ripe experience, and he will have had the friendly assistance of Mr. W. J. Cox, long familiar with local conditions, in arriving at a conclusion. The opinion used to prevail in the San Juan region that the gold-silver veins became impoverished as they passed out of the andesite breccia into the underlying sedimentary rocks. In that part of Colorado a great thickness—10,000 feet at its maximum—of lava flows and breccias lies upon the sedimentary series, the highest member of which is a Tertiary conglomerate, next to which come the limestone and sandstone beds of the Jurassic and Triassic. While some productive mines have been developed along lodes enclosed within the sedimentary rocks, it has been proved by experience that the much richer veins in the great covering of breccia do not continue into the sedimentary terrain and become impoverished before they reach that horizon. Our recollection is that the lower adit of the Camp Bird is fully 2000 feet above the conglomerate, so that there is an ample margin of safety, say, 1000 feet, between this low level adit and the limit of possible productivity. A number of veins should be intersected and a large territory prospected without great cost, having regard to the value of the orebodies already exploited in the existing upper workings. It is a reasonable venture and well worth while.

STATISTICS can be made to prove anything, simply because any sort of vague data can be given statistical form. For example, the mineral statistics published at the beginning of each year are notoriously inaccurate. Even those of the Geological Survey have to undergo radical revision before they can be accepted as part of the historical record. While it is comparatively easy to collect the figures of domestic mineral production, it is much more difficult to get at those of foreign countries, for the simple reason that in most cases no figures are issued by the various governments and mining bureaus until late in the ensuing year, if then. Yet this does not deter the *Engineering and Mining Journal* from giving a detailed tabulated statement of the world's gold production. Such a statement is farcical. Only the output of gold in the United States and the British dominions is obtainable, even estimable, with any accuracy, in the first week of the year. In making such an estimate, it should be indicated that 10 out of the 17 items are mere guesses, some of them bad. The idea that the gold production of China, Europe, or South America during 1915 can be estimated within $5000 on January 1, 2, or 3 of 1916 by an arithmetician in New York is preposterous. As Disraeli said long ago: "There are three kinds of lies: lies, damned lies, and statistics."

The Mexican Crisis

In our last issue we recorded the killing, by Villa bandits, of 18 Americans on their way to the Cusihuiriachic mines in Chihuahua. The party included several mining engineers well known in the West, notably C. R. Watson, Charles A. Pringle, William J. Wallace, and Thomas W. Evans. The news of the murder has excited keen indignation, which, after a lull, has been reawakened by the arrival of the bodies of the victims at their home communities. At El Paso a riot broke out soon after the news was received there, and talk arose of mobilizing a force of a thousand men to exact reprisals. A number of prominent Mexicans had to be deported to California in order to prevent a lynching. But the first feeling of resentment has been calmed, so that thoughtful men can put the question: "What is to be done?" A crime such as that perpetrated at Santa Ysabel on January 10 excites the emotions first, and then arouses the intellect to logical effort. Something has been done already. José Rodriguez has been captured and shot. Sundry legislators in Congress have availed themselves of the chance to attack the President's policy, which is

vulnerable; Mr. Theodore Roosevelt has delivered himself of a forceful denunciation, which is easy; Mr. William Randolph Hearst has mobilized his many-headed reptile press to stir the country into intemperate action, which is not surprising; and all the while thoughtful men have recognized that in this affair, as in that of the Italians at New Orleans, it is necessary to give the Government of the country a chance to punish its own criminals before we can take action in behalf of the victims of the atrocity. Let us examine the facts, as far as they are known. The statement that the murdered men were "too previous" in going to the mines is negatived by the assertion that General Alvaro Obregon, for the Carranza government, invited Americans to return to their mining properties and accompanied the invitation with assurances of their safety. They were duly authorized by the authorities at Juarez and at Chihuahua to proceed to their destination at Cusi, as it is generally known among mining men. So no blame attaches to the unfortunate victims on the ground of foolhardiness. At the same time it should be recorded that the State Department at Washington had not withdrawn its urgent warning to its own nationals against endangering themselves by going into parts of Mexico where guerilla warfare was in progress. Next, it appears that the deed was done by Villa's men, suggesting that, apart from his predatory tactics, he would be glad to embroil the United States with the Mexican people, for thereby he would get a chance to appeal to national prejudice and patriotic impulse. If this country were to intervene forcibly, Villa would be a military asset to the Mexicans, for, thrice damned brute as he is, he is a natural soldier and could not be shelved by a Mexican president in time of national need. Thus the crime was partly political, we think. For that reason alone the *de facto* Government has cause to regret the incident and, we believe, will be particularly anxious to placate American sentiment by punishing the murderers. The killing of this party in Chihuahua is a denial of Carranza's claim to having secured control in that part of Mexico. His government is disgraced by the act and must be anxious to prove itself able to enforce punishment. The recognition of Carranza pre-supposed his ability to maintain order; it was a long shot perhaps, and unless he moves quickly in this affair his claim will be stultified. We must give him a chance to make good. Meanwhile military intervention is no more warranted now than a month ago or a year ago; we do not see that this horrible crime should cause a change in the deliberate policy of the administration at Washington, any more than any one of a dozen other crimes perpetrated against American life and property during the last three years. The moment for forcible intervention was when General Funston and his troops were at Vera Cruz, and in a position to stand astride the railway to Mexico City. The President's policy has been termed consistent, which it is; it has also been called 'heroic,' which is a satire, even in days when heroic is a word much over-worked; but it may be sagacious. Anxious as we are to see Mexico pacified and mining operations resumed in that great mineral region, we believe that the solution of the problem must now be left to the Mexicans. This country is committed to that policy. If it succeeds, the historian will call it wise; if it fails, and armed intervention is finally necessitated, the historian will condemn it in strong language, as many people are doing already. It remains for all good citizens to support the national policy until Congress refuses any longer to sanction it. Hence we regret the violent language of an ex-President like Mr. Roosevelt. It smacks too much of politics. In any case, the endorsement by him of an editorial in the *New York American* is greatly to be deplored. No good can come from applauding the efforts of a prostituted journalism or supporting the diatribes of a publisher not remarkable for high principle. Remember McKinley. The man whose string of yellow papers reaches across this continent is trying to drive Mr. Wilson, as he drove William McKinley, into war. Has Mr. Roosevelt forgotten what he himself said soon after the assassination of McKinley? While never anything but a dangerous leader of opinion, in this case Mr. Hearst is particularly suspect on account of his large holding of lands and ranches in northern Mexico. No, the friends of the murdered dead do not wish, we venture to say, that their loss should be used by reckless politicians or a pestilent press to hurry this people into a war in a fit of resentment against the crime perpetrated by a beaten revolutionary desperado. Wherever Mr. Hearst leads, it is well to hang a red lamp.

Learning to be a Metallurgist

In this issue we publish another of our series of interviews. The subject this time is Mr. Philip Argall, an engineer particularly associated in recent years with metallurgical work in Colorado. Our readers will find the interview deeply interesting; it is the record of a keen student, a hard-working man, and a resourceful manager. The term 'self-made' has been used too much, like the adjective 'practical,' as an excuse for the uneducated and the uncouth, so that it has lost its real significance, but if ever there was a man that hewed his way to success, that found the *carrière ouverte aux talents*, that owed little to good fortune and much to earnest endeavor, then Philip Argall is the man. Consider the beginning: the small boy that rummaged among the sluice-boxes and found a little nugget of gold, and in the act became infected by the longing to seek and to find, by that call of the mineral explorer that takes the adventurous to the ends of the earth and to the waters under the earth. The boy had an education that was not conventional; indeed, the shallow-minded might be inclined to say that if he had gone through the regular preparation of school and university he would have done better. We doubt it. Of education it may be said, as of many other things, that we get out of it what we put into it. To be among mines and smelters, to work in a concentrating mill, and to be in close touch with those actually engaged in winning the metals from ores is not

necessarily a mining education, if the recipient is lazy or unobservant, but to an alert mind eager to learn and anxious to become efficient, it is a veritable school of mines. Apparently the boy Philip had the happy gift of arousing the personal interest of his older acquaintances, some of whom took pains to help him by the loan of books or apparatus. That blow pipe of which he tells us was the key to a whole world of rudimentary metallurgy, for a blow pipe and a piece of charcoal constitute a blast furnace in miniature. And then came the "complete laboratory" found in an abandoned mine. That was the luck of the miner, of course; of the energetic seeker and intelligent exploiter. Thus the awakened faculties were trained and developed. What could be a wider eye-opener to the mind of a keenly observant boy than the phenomena of kernel-roasting and the leaching of copper ore? The formation of a nucleus of copper sulphide in a lump of mixed sulphide ore is one of the most subtle of metallurgical operations, while the leaching of copper ore affords a typical example of the impact between chemical and economic factors.

With adolescence came hard work in a mine, the learning of practical details underground, and the comparatively rapid winning of a post of responsibility. At 19 the boy Philip became the man Argall, for at that age he was appointed a shift-boss in the Cronebane mine. But routine work was not allowed to interfere with further study. Witness the detection of hydrogen as the cause of underground explosions due to gas arising from the precipitation of copper in the mine-water. Then came the designing of a brake on a whim; his first application of mechanical ingenuity, to be evinced during later years in the invention of a classifier and a roasting-furnace. And then, after 25 years in Ireland, Mr. Argall went to Swansea, which at that time was the Anaconda of Europe, as a centre of copper-smelting industry. But Swansea was reactionary and unprogressive, and in that respect wholly unlike the Washoe works; for that fault it has paid the penalty of becoming a melancholy 'has been.' However, in 1880 Swansea was yet in its glory as the recipient of all kinds of ores from every quarter of the world. And what was more important to the subject of our story, it was the locality chosen by Parnell for several ingenious methods of his own devising, including a complex copper process of the Hunt & Douglas type, now only of academic interest. One of Parnell's ventures was the treatment of tin-scrap, in which operation the young Irish-Cornishman from Wicklow had a chance to discover that sulphur rendered tin unfit for plating, and so to remedy a defect in the process. Other experiences followed, including zinc mining and antimony smelting, after which a wider horizon was opened by a journey to New Zealand and Australia, with visits to France and to Mexico. Shortly afterward his appointment as manager of an important smelting enterprise at Leadville, when Mr. Argall was 33 years of age, brought him to the West, with which he has been identified ever since. The La Plata episode was no picnic, for the cut-throat competition between the Leadville, or 'mountain,' smelters and those of the 'valley,' at Pueblo and Denver, called forth all the resourcefulness of a strong character. His story of the decision to shut down is full of human interest. Five years later came his first contact with cyanidation, in the technology of which process Mr. Argall has written his name enduringly. In the controversies between dry and wet crushing, between roasting and non-roasting, between sliming and non-sliming, he played a prominent and useful part. The treatment of the telluride gold ores of Cripple Creek gave him a congenial problem, which he attacked with all the intensity of the Celtic temperament, incidentally waging a technical war of considerable vigor with the advocates of both bromination and chlorination in Colorado. The logic of events has proved his judgment to have been right. Finally, as first consulting engineer and then manager of the celebrated Independence mine, at Cripple Creek, he was able to put all of his ideas into effect in the construction of a large cyanide mill that made a remarkable record. A cost of $1.51 per ton and an average extraction of 74.57% on dump ore speaks for itself, at least to those conversant with similar problems. And then, as if to prove his up-to-dateness, Mr. Argall became involved in the use of flotation, achieving a noteworthy technical success so quietly that the mention of the fact in this interview is the first publication of it. For three years at Magdalena, New Mexico, he has been winning 95% on a mixed zinc ore, by the use of a film-suspension process of the Wood type. And so we bring this summary to the present time, when Mr. Argall is engaged in consulting practice with two of his sons at Denver. Having fought single-handed for instruction in science, he has given his sons the best education available, including a university training, thus affording them opportunities foreign to his own youth. Surely the United States has a good citizen in the man that has done so much to develop its mining industry and then contributes five sturdy intelligent sons to the community, not omitting the capable daughters, who being voters in Colorado, are also citizens in good standing.

We like the choice of a "best achievement." Mr. Argall says it was the introduction of the 8-hour working day in the cyanide mills of Colorado. There speaks sympathy with his fellow-men; such a manager can get more effective work in 8 hours than the small-minded autocrat who thinks the manual laborer is only a slave to be driven to his toil for 12 hours. But the dominant note in this fine career is expressed in the early part of our interview, where Mr. Argall acknowledges that he has been a student throughout his life. "Modern mining and metallurgy keeps one a continuous student, however humble his part." Yes, indeed; and not only in order to keep at the head of the procession but to enjoy that sense of useful power that comes to him who is gaining persistently in his understanding of the diverse operations of Nature. When John Richard Green, the historian, was dying, he asked that his epitaph should be: "He died learning." To be able to learn until the last summons is the wish of all thoughtful men.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Why Is Flotation?

The Editor:

Sir—I have read, in your issue of January 1, Mr. Huston's interesting discussion of this subject. Mr. Huston's article shows close observation of flotation phenomena, but I am by no means ready to admit the correctness of the preferential affinity theory of flotation, and since he has opened the discussion, I shall take this opportunity to present some further evidence in support of the electro-static theory.

It is undoubtedly true that oils, in general, have a greater adhesiveness for dry sulphides than for dry gangue-minerals, but I cannot see how this in any way proves that water will displace oil films from the gangues and not from the sulphides, or even that these films will be present to be displaced. Some of the transcript of the case of Minerals Separation *v.* Miami Copper Co. is now available, and it was certainly shown that unoiled particles could attach themselves to air bubbles. Entirely apart from this, Mr. Huston pre-supposes the presence of oil in the pulp. I have myself carried out flotation tests with a fair degree of recovery in a saturated brine without the use of any oil whatever. While the use of small amounts of oil improved the results, it was certainly true that there was a marked selective action in the brine alone.

Such work as I have done along this line would show that the main function of the oil is to lower the surface tension, and to form a surface film that is flexible, and at the same time coherent enough to get in contact with more of the sulphide surface than the tightly stretched film of a bubble in plain water. There have been several articles in the PRESS lately, in which theoretical and experimental proof has been presented showing that gangue-minerals possess negative electro-static charges, and that sulphide minerals possess positive charges. This explains why the flotable minerals will adhere to the flexible bubble-film, while the gangue-minerals will not. In other words, it explains the selectiveness of the process. The other details, it would seem to me, are largely mechanical. The oil may cause the sulphide particles, after they are in contact with the bubble, to adhere together in a coherent armor. Other mechanical effects, with various oils and various processes may be noticed, but the question "Why is Flotation?" must be answered by telling why one portion of the ore floats while the other does not. To determine this we must, of course, study differences in physical properties which parallel the flotation properties. It may be perfectly true that galena and the common sulphide-minerals differ from the gangue-minerals in their air-water contact angles and in their adhesiveness for oil, but so far as my information goes, the electro-static parallelism is the only one that explains the flotation properties of bad gangues and artificial sulphides.

JAMES A. BLOCK.

Salt Lake City, January 8.

Precipitation With Zinc

The Editor:

Sir—In your issue of December 11 there appeared an article on zinc precipitation, by J. A. Carpenter, which is of timely interest, for, as Mr. Carpenter states, the present high price of zinc has driven metallurgists to a closer consideration of precipitation methods. In the course of his careful comparison of figures, Mr. Carpenter advocates the use of zinc-thread by inference, although admitting the effective results obtained by the use of zinc-dust.

The interesting and essential feature to workers in the field of cyanidation, developed in this article, is that the saving in the cost of treatment was effected by a change in the regulation of solution contents, in lime and cyanide, rather than by the character of the precipitant, or the method of using it.

Had zinc-dust been employed, I believe that the results would have been substantially the same as those noted in the article in question. Not every ore will yield an equally satisfactory extraction within as wide limits of cyanide and lime contents in solution; hence it is clear that the reduced zinc consumption noted by Mr. Carpenter cannot be attained similarly in other plants by the use of the same tactics as those found practicable with the West End ore, unless the whole set of conditions were found to be parallel.

Mr. Carpenter's point is well taken, that the precipitation-presses are costly, and the less expense of operation with zinc-dust must hold for a considerable period, to offset the high initial outlay as compared with zinc-boxes, which are relatively cheap. On the other hand, he makes reference to "an occasional bad cask of zinc-dust" and the trouble it will entail.

Moist and caked zinc-dust is generally thought to have become entirely unfit for a precipitant, but this is not necessarily the case. In cases known to me, caked zinc-dust, which had been wetted in transit, was cast aside as worthless, or unsafe to use, and later, when force of cir-

cumstances required using it, it was dried and broken up to as near a powdered state as could be, and then fed into the solution in quantities of some hundreds of pounds. No bad results ensued, either in precipitation or extraction; although it was feared that the former would be seriously affected, in accord with the generally accepted belief about wet zinc-dust.

Although no 'short zinc' troubles the operator who uses zinc-dust, a zinky precipitate may be handled as follows: assume two precipitation circuits, in which the richer solution is incompletely precipitated, giving a high-grade precipitate and a nominally 'barren' effluent solution. The poorer solution is precipitated in most cases to 0.02–0.01 oz. silver; the question of precipitating to a 'trace' being purely a commercial one.

The second precipitate will contain more zinc than the one from the richer circuit.

With adequate solution-storage capacity, the zinky precipitate from the poorer solution may be raised in fineness prior to clean-up by pumping the richer solution through the press, and returning the effluent solution from the press to the stock-solution circuit. This parallels the return of short zinc to the head of the boxes, but has the advantage that no handling or preparation of material is required.

Naturally, it is preferable to avoid an excessive feed of zinc-dust, rather than to remove it afterward. With this point in view, a satisfactory method of avoiding excess of zinc and one affording a closer regulation than daily assays in a silver cyanide plant, is that of colorimetric titration of solutions at suitable intervals.

A titration scheme may be devised so that it can be run quickly through with a minimum manipulation and sufficient accuracy.

As Mr. Carpenter pointedly states, the best reason for choice of zinc-thread precipitation is found in the question of capital outlay in equipping plants when the duration of mining operations is a matter of more than the customary uncertainty.

Pachuca Tanks

The Editor:

Sir—In your issue of December 11 there is an article on 'Precipitation with Zinc Thread' by Jay A. Carpenter, in which he gives very interesting and valuable data regarding the use of this precipitant; but in the preamble of the article Mr. Carpenter, in using a simile to give force to an argument, makes what I consider an unfair criticism of the Pachuca agitator. The passage I refer to is as follows: "At the time of the growing popularity of the Pachuca agitator, it would have been heresy to publish the fact that they filled gradually with solidified pulp, and it was not until their popularity was on the wane that this was asserted in print."

If, instead of using the sweeping expression "they filled gradually with solidified pulp," the writer had said that "some filled gradually" I would have no complaint to make, as I am well aware that when a Pachuca is not correctly installed and properly operated there may be trouble; but this applies equally to all our modern mill machinery, and there are "some" tube-mills that do not grind properly, "some" vacuum-filters that do not filter successfully, and "some" zinc-precipitation arrangements that do not seem to take the precious metal out of the solution, and even "some" cyanide plants that won't work.

It seems to me that the use of such a broad and inclusive statement is, first, not fair to the agitator itself, which is now in service all over the world, and secondly, a severe reflection on the intelligence and business ability of those in charge of the large plants where Pachucas are in operation. If Pachuca agitators "fill gradually with solidified pulp" they would soon be on the scrap-heap, as untreated pulp is of more concern than the apparatus used for treating it.

Some incidents in connection with the early history of the Pachuca may be of interest to your readers. I was in San Francisco in 1904, and, having letters of introduction to one of the leading mining men there, I showed him drawings of the apparatus, since called the Pachuca tank. He looked at it in a curious way, and asked if I really meant that in such a device a charge of 50 tons of settled pulp could be started up and kept in agitation, and when I answered in the affirmative, he brushed the drawings aside as though the interview were concluded, and remarked: "Why dynamite wouldn't shift it in such a vessel." After informing him that the apparatus was no longer an experiment, but that over 1000 tons of sand had been treated in it, he again looked at the drawings and asked me to explain the operation, and suddenly said "Why of course it will work; I think you have a valuable idea."

In 1905 I was at a mine where they shipped their concentrate across the ocean to smelters, and although fairly high-grade, there was little, if any, profit. The managing director approached me regarding local treatment, and it was decided to install a Pachuca, and one of 7 ft. 6 in. diameter by 37 ft. high was purchased from a neighboring mine and installed without delay. A 50-ton charge was immediately pumped into it, but owing to a break-down of some machinery, it had to stand for 10 days. When things were running again I was told to start up the Pachuca, and the men in the mill had a grin on their faces as I climbed to the top of the tank to operate the valves. In three-quarters of an hour it was all loosened up and a heavy lead weight, lowered into the tank by means of a cord, struck metal whenever it was bumped on the cone bottom, showing that there was no lodged concentrate.

I think the late Albert Grothe, of Mexico City, named the agitator the Pachuca. In 1904 I sent him drawings of the tank, and in 1905 he built a small one for testing purposes, and when he had his first charge in agitation, he threw a handful of buck-shot into the tank and was

astonished to find them lifted up and discharged from the central pipe. He said that an agitator that would handle buck-shot would suit his ore all right.

For simplicity and low cost of erection there is nothing to equal the Pachuca; no belts, no shafting, and nothing moving except the compressor; and when a tank is put in right, the quantity of air necessary to perform the mechanical work is just about what is wanted for the chemical requirements. Such a tank is especially suitable for cold climates, as it occupies so little space and can easily be kept warm.

An objection I have heard raised here to Pachucas is that it is difficult to raise the pulp to them owing to their height, as belt-elevators and centrifugal pumps are costly to operate. I always use a plunger-pump of the same design as is so successfully used in the clay-working industry to pump gritty clay into filter-presses against pressures of 80 lb. or more. At one mine I used such a pump for 12 years until the mine closed-down, and the pump was still perfectly good.

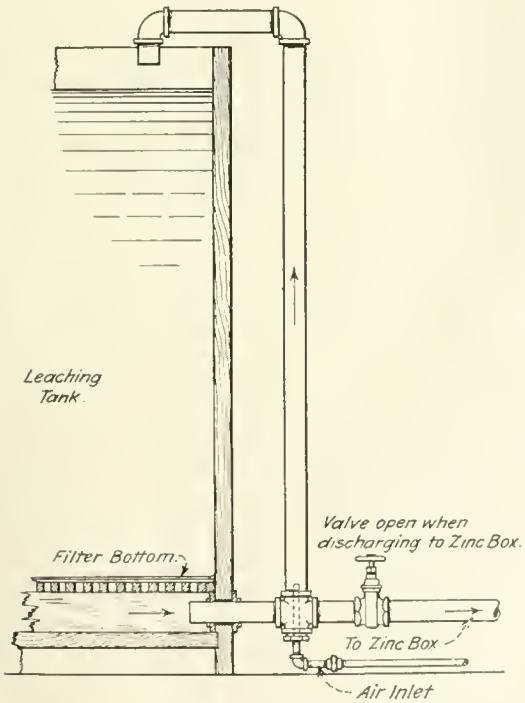
Boise, Idaho, December 29, 1915.

The Air-Lift in Leaching

The Editor:

Sir—While leaching seems an old-fashioned subject, there are a great many plants in which the leaching of



AN AIR-LIFT IN A SOLUTION-DISCHARGE TANK.

the sand is carried on with the agitation of the slime, so even at this late date, it seems to me, suggestions on the improvement of this phase of cyaniding are not out of place.

The Zopilote mill in Tepic, Mexico, was of this type. In order to increase the capacity of this mill, without additional equipment, it was necessary to increase the proportion of sand to slime in the crushing department and, to handle this increased tonnage of sand, the time of leaching had to be cut down. I accomplished this by the introduction of air-lifts in the solution-discharge of the tanks, as is shown in the sketch. In this way the solutions were kept in constant motion in the tanks and a freshly aerated solution was continuously supplied to the ore with a surprisingly small consumption of air, the lift being less than a foot and the total length of the column being less than seven feet.

This simple arrangement cut down the time of treatment 33% with an increased extraction and, at the same time, cut down materially the zinc consumption, as the solutions were not precipitated until they were much richer than under the old system.

Clarke Sullivan.

Wonder, Nevada, January 3.

[This idea was adopted at Kalgoorlie as far back as 1900; however, everybody may not know it.—Editor.]

Prohibition in the West

The Editor:

Sir—When a section of the country that particularly prides itself on its virile manhood and untrammeled liberty for the individual passes prohibition laws, such as the states of Arizona, Colorado, Idaho, Oregon, and Washington have done, it is time to discuss the matter. Not the least interesting part of Mr. Probert's article on Oatman in the first number of the year was his comment on the dry condition of that lively district. It is axiomatic and scarcely worth mentioning that copious experiences of North American communities with the prohibition experiment, from the Black Belt of the southern states to Canadian mining districts, have shown results so vicious as not to stand comparison with the public drinking in Western saloons. Little details like 'squirrel-whiskey,' tons of broken bottles behind the bushes, and enormous growth of the drug habit are scarcely in the same class as the direct masculine atmosphere of a saloon. Undoubtedly some temporary advantage to industry is anticipated, or such laws as prohibition could not find serious support. It is rather humorous to think that anyone who knows anything should believe that a law prohibiting drinking in saloons will persist after the novelty of the experiment has grown flat; a reaction against these Sunday-school reforms will undoubtedly come. The American people, particularly in the West, need prohibition about as much as they need a law forbidding the eating of pancakes or red pepper, both of which are surely bad habits. Attempts by cranks and faddists to limit the individual liberty of a people having the traditions of the United States can never achieve any lasting success. It begins to look as though there was a tendency to an unthinking exaggeration of such matters as temperance, sanitation, safety-first, efficiency, purity, etc., all of which are probably good in moderation.

P. B. McDonald.

Berkeley, January 4.

Aluminum Dust

By G. H. Clevenger

ALUMINUM dust is chiefly of interest to the mining man on account of its use as a precipitant of the precious metals in the cyanide process. It is also used as a reducing agent wherever a powerful metallic reducing agent is required, as, for example, in the production of carbon-free metals, particularly those difficult to reduce, or in the Goldschmidt process of welding "thermit" for producing *in situ* super-heated molten iron or steel. Another use is as a 'bronze powder' in the preparation of aluminum paint. Perhaps the most important use at the present time is in the manufacture of various explosives. This was first proposed by Escales of Munich in 1899, and, in 1900, von Dahmen patented the use of aluminum, magnesium, or other light metal mixed with an oxidizing agent. Ammonium nitrate was among the first used of such oxidizing agents. This explosive, called 'ammonal,' has given good results in mining and as a high explosive in shells. It has the advantage of being insensitive and very stable, as indicated by the fact that, in Austria-Hungary, shells filled with it were found good after ten years. The reaction taking place when ammonal explodes is probably represented by the equation

$$3NH_4NO_3 + 2Al = Al_2O_3 + 6H_2O + 3N_2$$

Recently aluminum dust has been added to many other explosives. Other metallic powders, as, for example, magnesium, copper, zinc, iron, silicon, ferrosilicon, certain of the rare metals, and various alloys are now used for a similar purpose. An example of the composition of a modern explosive using aluminum dust is as follows:

Ammonium nitrate	45 parts
Di or tri-nitrotoluene	1905 "
Aluminum dust	22 "

Below are given two representative analyses of good grades of aluminum dust:

	A.	B.
Al	91.20	92.50
Al_2O_3	5.80	5.72
SiO_2	1.30	
Si	0.40	1.78
C	0.23	
H_2O	1.07	
N	May also be present	

Aluminum dust is frequently adulterated with powders of other metals, particularly zinc and tin and, at times, also with mica. The difficulty of manufacture accounts for the relatively high cost of the dust, which, in normal times, is almost double that of the metal in other forms.

One method of manufacture involves the production of foil by a special system of rolling or combined rolling and hammering. The perfect foil is marketed in that form, while the imperfect foil, usually constituting 65 to 67% of the total is comminuted in two series of special stamp mills, the finished product being separated by bolting and winnowing. The final operation is the polishing of the dust in a special device. Another method is to force gas or air into molten metal while it is setting, accompanied by vigorous mechanical stirring. The granules thus formed are powdered in special stamp mills or in ball mills. The finely-ground dust is separated and polished by methods similar to those previously described. In all the methods of making aluminum dust, it is necessary to add stearine or some other wax, to prevent the welding together of the fine particles during crushing.

A source of much annoyance, if not actual danger, is the not infrequent explosions that take place during the various operations after the aluminum has become finely divided. It has been pointed out that this is probably due to the presence of an inflammable gas, since aluminum dust alone is not explosive. Carbon is always present in aluminum, presumably as the carbide, its source being the carbon electrodes used during the reduction of the metal. This, under the conditions obtaining in the grinding mills, probably produces methane. Thus 0.10% of aluminum carbide, which is not unusual, would be capable of producing 132.8 cubic inches of methane per pound of aluminum dust. In addition, there are the possibilities of the decomposition of water-vapor or the wax by the finely divided aluminum to form inflammable gases. These, mixed with air, are, of course, explosive.

Although a great deal of heat is generated during grinding, with ordinary precautions it seems improbable that the temperature would rise to the point of ignition of the gaseous mixture. Sparks might be formed through the impact of the steel grinding surfaces, but a more probable cause of ignition is the electrical discharges which are known to take place. This view is supported by the fact that aluminum dust at times ignites after it has left the mill, when allowed to stand in a solid pile. The dust becomes rapidly coated by a film of oxide which, although exceedingly thin, acts as an insulator. During grinding and polishing, a considerable amount of frictional electricity is generated. This is not readily conducted away on account of the insulating film of aluminum oxide. Potential differences up to 3000 volts are possible. Therefore, when the insulating film breaks down, electric sparks occur which ignite the gaseous mixture. Since it is impossible to entirely avoid explosions, the units for producing aluminum dust are made comparatively small and are provided with loosely fitted iron covers so that, in event of an explosion, little damage will result. In one case an explosion occurred in a new plant 1½ minutes after beginning operations.

DRILL-STEEL is a matter worth considering. It is not unusual for a large mine to buy 100 tons of drill-steel in one order, representing $15,000 or $20,000. Hollow steel, of course, costs much more than solid steel, in fact is usually quoted at prices 50 to 75% higher.

Philip Argall, and Metallurgical Progress

An Interview. By T. A. Rickard

Mr. Argall, your name suggests that you are of Cornish origin.

My father was Cornish, my mother Scotch-Irish. I was born in Newtownards, county Down, Ireland, in 1854, and was 25 years old before leaving the country. I used to call myself an Irishman until I became an American by naturalization, in 1889.

Was your father engaged in mining?

My father, Philip Argall, descended from a Cornish mining family, spent his lifetime in the mining business, commencing with tin, lead, and copper mining in Cornwall, leading to lead and coal mining in Wales, and, I believe, lead mining in the Isle-of-Man. At the time of my birth father was at the Conlig mine, near Bangor, this mine being at that time the greatest lead-producer in Ireland and possibly in the British Isles; the family moved to the Wicklow copper mining district in 1858, and a year later my earliest recollection of mining begins. Father left Ovoca in 1872 to engage in coal mining in county Tyrone; he died in Dungannon in 1887, in his 72nd year.

Have you any personal knowledge of the Conlig mine?

I visited the locality in 1911 and saw the ruined tower of the famous wind-mill that operated the crushing machinery in the early 'fifties. The large dumps of jig-tailing adjoining bore ample testimony to the power developed by this huge wind-mill, of which I heard father speak so often. In average weather it ran the whole dressing-works, but as a local wit remarked to father, "she had her off days, and in that respect was more human than the steam pumping-engine that was never affected by the weather."

The architecture indicates the work of Cornishmen?

Yes, the engine-house is typically Cornish; indeed, everything except the wind-mill would pass as an old-time Cornish mining scene. The general manager was Silas Evans, one of the foremost lead miners of his day; he too worked his way up from Cornwall through Wales to the Isle-of-Man lead mines and thence to Conlig.

I suppose the mine was abandoned after exhausting the ore?

Yes, father often said he considered the mine bottomed except at the bog shaft, and there the ore occurred in barite gangue, and they failed in raising the lead to marketable grade. I saw much barite in the dumps in 1911; also some evidence that recent attempts had been made at re-working them, evidently with unsatisfactory results.

What is your earliest recollection of mining?

Strange to say, it is closely connected with this great State of California. It was an attempt at gold mining on the Aughrim river, a tributary of the Ovoca river, county Wicklow. I remember a Californian miner in a red-flannel shirt; he was boss of the New Diggings. It was the first red shirt I ever saw. In the land of the 'sleeved waistcoat' he wore no vest; his hat had the widest brim it had been my privilege to gaze upon. For a year he was the hero of my childhood, and to this day nothing in my early life stands out so clear cut and so vivid as that Californian gold miner in 1859, with his red shirt, sleeves rolled up, hat tilted back. I see him yet, prominently posed on the bank shouting orders to the workmen below.

So you can recollect gold mining in Ireland: what became of this venture?

I remember the sluicing operation distinctly and also that in rummaging in the sluice after work was over I found something yellow one day, about the size of a wheat grain. They told me it was a gold nugget, the first found at that place. I date my mining career from that event. The placer mining did not prove profitable, and not finding veins, they collected the float-quartz from the hillsides and treated it in a stamp-mill erected to crush it. The stems were of oak and the hard quartz got the best of the cast-iron heads.

The next move consisted in roasting the quartz in a sort of lime-kiln, and quenching it with water, before stamping. The roasted quartz went through the battery without incident, that I can recall; then came the clean-up, and, as I learned afterward, no amalgam, so the mercury was finally volatilized in an iron ladle over the forge-fire and "like the baseless fabric of a vision left not a wrack behind." That process I saw, and realized some of the disappointment. The Irish quartz-rock proved too much for my red-shirt hero, who went out of my life, as it were, in mercurial vapor.

Can you recall any further gold mining in Wicklow?

Nothing of importance. In 1875 I assisted G. Henry Kinahan of H. M. Geological Survey, in looking over the placer workings; some three or four men were at that time eking out a scant existence with pick and pan. I re-visited the place in 1901 and heard that one old gold-miner was still active in the district.

What was the source of the gold?

Mr. Kinahan believed the gold came from the oxidation and disintegration of the pyritic lodes, and my subsequent experience in other countries inclines me to support that view.

Do the Wicklow copper lodes contain gold?

Yes, in minute quantity; it was only in the gossan that visible gold occurred, or immediately below it, in what is

now called the zone of secondary enrichment; assays of several ounces of gold per ton have been obtained in that zone.

Did you have any regular mining education?

Not of the college type; before reaching my 16th year I finished the grammar-school work, and obtained a grounding in Latin, and such familiarity with Macaulay, Shakespeare, and the English Bible, as has stood by me ever since. Shakespeare I disliked until I reached the years of maturity, but he has long since been my favorite author.

I spoke of mining education.

I am coming to that; when 16 I was laboring 10 hours per day in the dressing-works of the Tigroney mine and receiving a penny per hour as compensation. I soon learned about all that was then known regarding jigs, buddles, and copper-ore dressing, as well as the method then used in precipitating copper from mine-waters. I also studied three evenings per week with a tutor. At 17 I worked 8 hours per day in the mine and took two hours instruction daily from Capt. Chamley, an ex-officer of the Ordnance Department of the British army, on mathematics and surveying. We had at that time a sort of mining college on Stephens Green, in Dublin. I believe it was called the Royal College of Science for Ireland. The Wicklow mines were but 40 miles from Dublin and we saw much of the professors; they were very kind to me, giving me books to study and directing my reading in chemistry. I particularly recall Prof. J. P. O'Reilly, Prof. Robert Galloway, also, whose 'Qualitative Analysis' was my chemical 'horn book.' I owe much to these men and perhaps most to a scientist whose name I cannot now recall. I had shown this gentleman through the mines, and we were lunching together, when he asked me about the blow-pipe. I knew nothing about it. His conversation greatly interested me; he went out and scraped some of the mud off the road, explaining that the minute pieces of hoof and hair in the mud should react for ammonia in the closed tube. To my astonishment it did. He fixed me up with a blow-pipe and a list of books. These I procured, and set to work. He insisted on checking over my notes and within six months I was quite handy with the blow-pipe. To this scientist I am also indebted for notes, how to record the essential information in brief form, arranged for ready reference. I only regret he did not impress on me the importance of dates. In 25 years past I have on every available occasion told my assistants and younger friends that the date is often as valuable as the other data, sometimes more so, and should always form the first notation on every sheet.

How did you manage experimental chemistry?

I purchased some few pieces of apparatus and some reagents to putter along with, but at 20 I was fortunate in being able to pick up a complete laboratory apparatus, reagents and all, at a defunct mine. The equipment came from Germany at the time elaborate experiments were made by German metallurgists on the Connary ores.

In connection with the leaching of copper, I suppose?

Yes, kernel-roasting and copper-leaching. I visited the plant almost every day on my way home from school; the laboratory always commanded my admiration, and years afterward when I obtained possession of it I was a proud boy indeed, though I had borrowed more than half the money I paid for it. Some 30 years later I met the late George W. Maynard in New Mexico, and on comparing notes found he was in charge of the Connary mine when kernel-roasting was tried in 1866-8. We then exchanged much information of mutual interest and remained fast friends thereafter. I made good use of this laboratory and soon got out of debt by making sulphur and copper determinations; previously the former had been sent to Dublin and the latter to Swansea or Cornwall for assay. In the year 1879 I took a course in metallurgy at Swansea, Wales, then the metallurgical centre of the world as regards copper. Such was my mining education, or rather the basis of it. I grew up among mines and metallurgical works, absorbing practical details as I grew, and learning the scientific details later.

You remained a student always?

Yes, throughout my active life. Modern mining and metallurgy keeps one—if he expects to remain in the procession—a continuous student, however humble his part.

You were subsequently connected with the Wicklow copper mines, were you not?

Yes, I worked at all kinds of mining, driving, raising, sinking, stoping in both hard and timber ground. In 1873 I was promoted to shift-boss in the Cronebane mine, and two years later was assistant-manager with title of Captain, as Cornish customs prevailed there.

You have written about copper precipitation underground at that property?

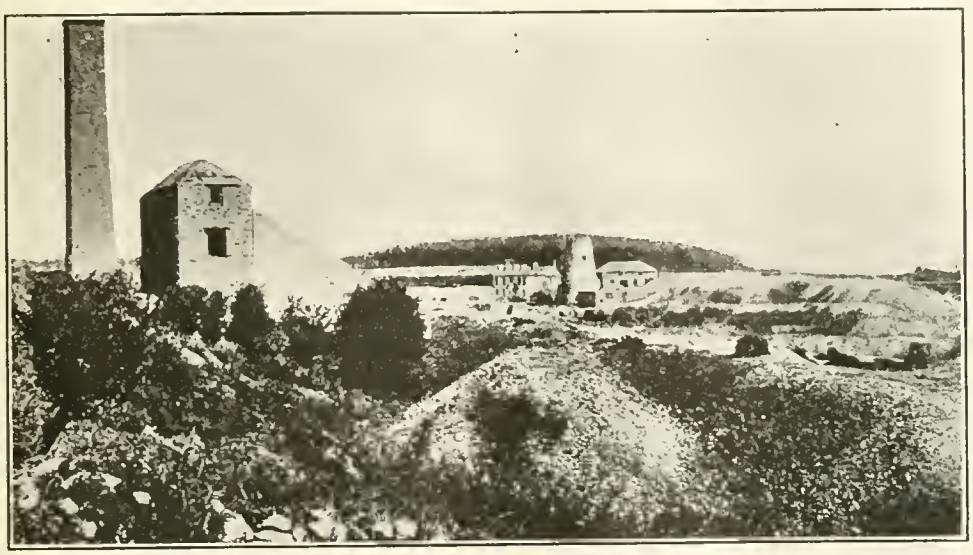
The Cronebane mine did not command the mouth of the main adit. I knew from repeated analysis of the waters that our mine was furnishing its principal copper content. When the manager was fully convinced that the copper came from our property and that it could be precipitated from the mine-waters underground, a demand was made on the Tigroney company for a share of the profit and was turned down hard. My people still had an obsession that precipitation in the mine might lead to some complication, so I was first instructed to place 100 ft. only of launders; these were filled with tin-plate scrap, the precipitation was simply wonderful, the precipitate assaying nearly 90% copper. The result I soon learned was due to the clear warm water that was collected near its source in the mine, as compared with the cold muddy water, often laden with ochre, that fed the surface precipitation plant. Well, the full plant was then ordered in and in a few months was operating satisfactorily.

So copper precipitation in the mine was an unqualified success?

Not completely so, we had two setbacks that I recall.

What were they?

We had to use all the available space in the mine for precipitation. One unventilated cross-cut 600 ft. long caused the first trouble; following a triple holiday, an explosion took place, burning two men rather painfully. An explosion in a metal mine so alarmed the chief Mining Inspector that he wired us to leave everything as it was, pending his inspection. We did. I, however, started an investigation on my own account. I had often noticed gas bubbles rise through the clear water, in the launders, so I collected and tested this gas, which proved to be hydrogen. That night I crawled without a light into the cross-cut to where a hole went up in the roof and there collected a wash-bottle full of the air. On reaching my laboratory I began and ended my investigation by holding a light to the mouth of the flask, I had a real first-class explosive mixture in it.



CONLIG MINE, COUNTY DOWN, IRELAND.

When the Chief Inspector arrived he was placed in my charge; I told him it was hydrogen gas that caused the explosion, showed him the gas bubbles, collected some, and tested them for him. We then entered the cross-cut with Clanny lamps provided by the inspector, Mr. Dickenson of Pendelton, Manchester, who gave me my first instructions in the use of safety-lamps, and formulated rules for the daily inspection of the 600 ft. of cross-cut before the men were allowed to enter. Mr. Dickenson was greatly impressed with my work on the cause of this explosion and the remedy applied. He gave me prominent mention in his dispatches and annual report, and later when I left for Cornwall he wrote the Inspector for that district, R. J. Frecheville, to look me up.

What was the other incident you referred to?

At one point on the upper adit a Cornish horse-whim, with two buckets, was utilized to lower the cast-iron used in precipitating. I saw that if a brake was applied the horses might be eliminated. I got out a design for a brake on the top of the vertical whim 22 ft. from the ground, with rods and levers to the shaft-collar. The manager finally approved the design, but discarded the lugs I had provided to keep the brake-band from rising. The brake worked nicely on the evening it was finished. The next morning we had snow and ice, and in lowering the first bucket of iron, a lump of ice caused the brake-band to lift and slip off the friction-blocks, with the result that the bucket and 1200 ft. of steel-wire rope, the second I ever saw, went down the shaft, I believe it took a week to clean up the wreck. Afterward this apparatus gave great satisfaction.

You wrote some papers on the Ovoca mines?

Yes, two, one describing the geology and ore desposits, the second in collaboration with G. A. Kinahan, on copper precipitation. Both were published by the Royal Dublin Society. The plan and section in the former paper were awarded the first prize for the best plan and section of any mining district at the Cornish Polytechnic Society's exhibition in 1878.

I remember an article of yours describing the precipitation of copper from the water of the Ovoca mines and the introduction of the mono-rail underground.

I wrote one paper describing the mono-rail, in connection with the precipitation of copper, in a drift where two lines of launders were established: car-tracks could not be used, so the mono-rail was devised for transporting the heavy cast-iron and the copper precipitate, and proved a great success. It is described in the MINING AND SCIENTIFIC PRESS of July 28, 1906.

A revival of the copper industry in Wicklow was attempted in later years?

Yes, but nothing came of it. Some friends induced capitalists to re-open the zone under the gossan explored in 1875-8. I had the records of hundreds of assays I made during that period, as well as my original surveys. Several pits were sunk at places I selected under promise of 3% copper; the ore found, however, averaged nearly 4% copper, about one quarter of which was soluble. Instead of mining the ore in mass (it was about 40 ft. wide) and treating it by some modern process, the new operators followed the practice of the previous centuries, in attempting to dig out the fine seams and stringers of high-grade in the shale and sending the ore to Swansea for reduction. On that basis the enterprise proved unprofitable. A steam-shovel proposition was tackled with pick and timber, and the result was inevitable.

How long were you at these copper mines?

I came there as a child and left in my 25th year to take charge of the Stannic works at Swansea, South Wales.

What kind of business was that?

The principal business was removing the tin from tin plate scrap; tin and copper matte-smelting was also carried on to some extent; puddling-furnaces and a steam hammer formed another part of the plant. The Parnell process used then contemplated the removal of the tin from the scrap in a hot solution of sodium sulphide, evaporating the spent liquor, roasting to produce tin oxide and sodium sulphate, smelting the tin oxide, in Cornish furnaces. The iron scrap was heated in the puddling-furnaces and beaten out into blooms under the steam-hammer. In a word, Mr. Parnell intended to sell block tin and tin-plate blooms to the tin-plate works across the valley, so that both the tin and the iron might enter the channel of trade a second time in the form of tin-plate.

Did he succeed in this?

No, both the tin and the iron proved to be 'cold short'; the former could only be sold for some £15 per ton below standard tin, and the iron was unsaleable except for desulphurizing in lead-smelting. At the time I took charge of the works no one had ascertained what was the exact trouble with the tin, though considerable money had been spent in complete analysis of the refined tin; the iron had up to that time been forced into a mold under the steam-hammer and the compact balls sold to the lead-smelters. On entering the refinery one day our Cornish refiner was struggling with what looked like a very tough slag; I said, "What is that you are trying to pull out of the furnace?" He said, "I don't know; I have been 30 years smelting tin and never saw no such stuff before"; he continued, "if I was them there chemists I'd assay this devilish stuff and not fool with the block tin." I took the hint, secured good samples, chilled them, and set to work, and soon found that the metallic substance was mostly tin sulphide reduced from the sulphate left in our tin oxide. I then determined the sulphate present in the batch of oxide we had ready for smelting, added lime to correct it, and smelted. I believe, a dozen samples, testing each button and finding every one best-grade tin. But I wanted John Uren's opinion; I had worked through the night and our refiner was late in arriving. I placed all the buttons in a ladle and poured several test-bars on the marble slab; when John arrived he nicked and tested each bar and said "It's best Banka, where did you get him." I replied, "It is our tin scientifically smelted."

I had obtained this, my first independent job, on four months trial; the time was about up, so I repaired, after breakfast, to the head office and emerged from a directors' meeting an hour later with a year's contract in my hand and 50% advance in wages, provided I kept the tin up to the grade of Banka in the future. With the assistance of John Uren, the Cornish refiner, this happy result was maintained, and John, too, who gave me the 'stuff' to work on, was duly rewarded.

What quantity of sulphur will render tin 'cold short'?

About 0.02% sulphur will render tin unfit for tin-plating, 0.03 to 0.04% will render the tin quite brittle; in testing a bar containing, say, 0.04% sulphur by nicking and bending, the 'cry' will be dull, the fibre does not develop, and the bar breaks after slight bending. However, after so many years, I am not positive as to the exact percentage of sulphur.

Did you experiment with this iron-scrap?

Yes, I started the furnaces and made about three tons of blooms one day. The iron worked beautifully under the hammer, and being at that time short of rabble-heads we forged a score or so. The next morning, on entering the forge, I saw several broken rabble-heads; they were so brittle that they broke in several pieces in being dropped on the cast-iron floor-plates.

Was that due to tin in the iron?

Yes, in rolling the tin-plates after dipping, to remove the superfluous tin, a double or perhaps treble thickness forms on one edge of the plate. That thickened edge was our undoing; if we left the tin-plate scrap in the solvent long enough to dissolve the extra thickness of tin on the edge, sulphide of tin was precipitated on the larger portion of the plate, greatly reducing our tin recovery; furthermore, there appeared to be a sort of tin-iron alloy in the pores of the plates that could not be removed. This tin rendered the iron 'cold short.'

Did you try other means to remove the tin from the scrap?

Yes, and succeeded by using a weak solution of lime chloride as a dip, before feeding the de-tinned scrap to the puddling furnace. This gave us a higher recovery of iron in blooms and quite free from tin, which latter was volatilized as chloride. We ran a batch of five tons of blooms, sold them to the tin-plate works, where they were rolled into plates and covered with our refined tin, thus realizing Mr. Parnell's ideal, but the blooming process would not pay.

What did you do with the iron after that?

The rabble-heads we made proved much superior to common iron in skimming furnace-changes, and we supplied the copper-smelters with rabble-heads at good profit. Later, we sold them ladles of the same iron-tin alloy, beaten out under the steam-hammers and pressed into form in molds by the same hammer.

You spoke of blast-furnace smelting?

We smelted several thousand tons of tin-slag in our blast-furnace and did very well, using puddling-furnace cinders to break up the tin silicate and incidentally accumulated quite a bit of 'hard head,' a tin-alloy, the subsequent treatment of which caused more trouble than anything else about the plant. I left considerable of it for my successor to work up.

What about copper-matte smelting?

The business was controlled by a large firm of ship-owners who picked up cargo in various places and sent it to the Stannic works for reduction. I recall a large cargo from Algeria, containing gold, silver, zinc, and

2% copper. It was my first experience with zinc, and I had a very bad time of it with 12% in the charge. In the midst of my troubles your uncle, Richard White Rickard, dropped in; I believe the ore came from his mine; we became good friends and he proved a great help to me later; permit me to say he was a splendid engineer, one of the best informed men I had met and an all-around good fellow.

Did you remain long at Swansea?

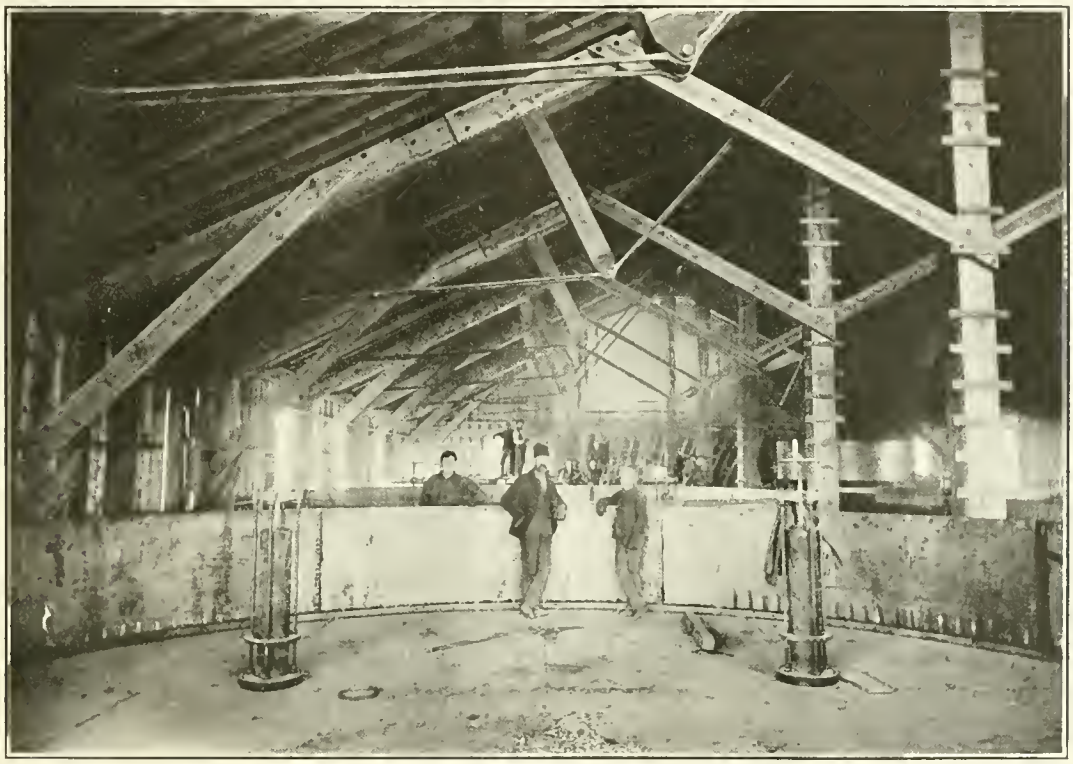
After a year and a half my health suffered from the ever-present sulphur fume, so I left with the good wishes of the board, and a handsome testimonial from Mr. Parnell for "improving and completing his process." I

boyish questions. I remember also that the mine was exceedingly hot, and of being awakened to an appreciation of the heat generated by chemical decomposition. If I remember correctly, you went soon afterward to New Zealand, on the recommendation of my father?

I did, but first I spent a year in London as manager of the Barking Metal Works. Antimony smelting and refining.

How did you like that position?

Very much, it was extremely interesting and instructive work. The smelting was done in crucibles, using salt cake, and rich slag, with tin-plate scrap for desul-



RIVETTING A 30-FT. STEEL TANK, METALLIC WORKS, FEBRUARY 1895.

returned to mining, accepting the management of the Glenariff Iron Ore & Harbor Co., in county Antrim, Ireland. The supervision of extensive mines of aluminous iron ore, pisolitic, below the basaltic plateau, ten miles of railway, and the fascinating geology of the Glen kept me busy for a year, during which I published a paper on 'The Tertiary Iron Ores of Antrim.' Mr. Rickard next offered me the management of the Duchy Peru mine in Cornwall, of which he was then consulting engineer; so in 1881 I found myself mining zinc-blende with siderite gangue, hand-sorting the coarse ore and wondering what I would do with the fine, of which my predecessor left a large tonnage for good measure.

In what part of Cornwall was that?

The great Perran iron lode in the parish of Perranzabulo, about six miles from Newquay. Perhaps, Mr. Editor, you will recall that I first met you at that mine.

Indeed I do, and how kind you were in answering all my

phurizing; the product from the first smelting, called 'singles,' was re-smelted with alkaline flux and excess of antimony sulphides, two buttons 'single' formed a crucible charge, the product was called 'doubles' or 'star bowls.' The 'doubles' were melted, and refined, with a special so-called secret flux, which was allowed to cover the plates in the mold to develop the 'star.' Our product was sold as French star antimony, and so far as I could see, it mattered little what the composition of the metal was, so long as it had a good crystallization on the surface—the much-desired 'star.' The refiner was a secretive, independent, and in his cups, insolent man. As he was inimical to proper discipline, I dismissed him, but before leaving he tampered with the refining flux. I promoted the man on the 'doubling' furnace to refiner, but he could not produce the 'star:' together we tried all sorts of mixtures of pearl-ash, adding various salts, including tin, which was believed to

help the starring process, hence the use of tin-plate scrap in the first smelting. The third day we threw away the old flux and began experimenting with fresh salts, and with the knowledge and assistance of the new refiner soon produced the much desired 'star.'

Did you introduce any improvements in the plant?

No. We were designing furnaces to smelt the ore in quantity and preparing to put in a lead stack for silver ores when the sudden failure of Richards Power & Co., in 1883, closed up the works. Lord Penzance had the largest holding, but having been mislead by R. P. & Co., refused to continue operations. I realized on the stocks, the company was wound up, and I went back to Cornwall to pump out the Old Duchy Peru mine, just purchased by Brown Bros., of St. Austell.

What was your next move?

Your father, Mr. Thomas Rickard, kindly recommended me to the Kapanga Gold Mining Co., and I obtained the management of their mines at Coromandel, across the Hauraki Gulf from Auckland, in New Zealand. The Kapanga was a specimen-gold mine and the most disappointing I have ever operated; I got the tail end of one small pocket and insufficient funds to find another. The only incident worth recalling is the discovery of auriferous native arsenic, the collection of, I believe, 350 lb., of this metal from the dumps, and extracting about 50 oz. of gold from it. The pin I am wearing is native arsenic from Kapanga.

You were not long in New Zealand?

About a year. I traveled a good deal, called at all the principal ports, saw some of the best mines, visited the hot springs and volcanic district, and greatly increased my knowledge of geology and mining. I spent a few weeks in Australia, on my way back to England.

What was your next move?

Some mine examinations in France; then I met one of the Brown Bros., who offered me the superintendency of a group of mines in Sonora, Mexico. The Los Bronces and Animas mines in the Barranca district.

In what year was that?

In 1886.

How long were you in Mexico?

Almost one year. The company operated under the name of The Silver Queen United. I found a concentrating mill under erection, and no water with which to operate it, and indeed very little ore either. I procured boilers, steam-pumps, and about three miles of pipe, unwatering three or four mines without filling the reservoir, but we finally got started and made very irregular runs, because of the many shortages of ore and water. The last Rittinger percussion tables I saw in use were in this mill: we had, I believe, four of them. At Bronces the company had a dry-stamp mill and hyposulphite leaching plant. Realizing that the company had not obtained title to the property, and that its finances were in poor condition, I left at the first convenient opportunity and returned to London before the crash came.

What was your next position?

Consulting engineer to the Mountcashel Iron Ore Co., in Antrim, Ireland. I built a concentrating mill of 200 tons daily capacity to recover the hematite pisolites from the aluminous gangue. The plant was quite a success. In the same year (1886) I was appointed consulting engineer to the Société Anonyme de Plomb D' Asperieres, operating on the river Lot, near Capdenac, Aveyron, France. A large concentrator had been erected against my previous advice to the company, and it did not treat the ore satisfactorily. The silver-lead, carrying an ounce of silver per unit of lead, was as soft as graphite and was enclosed in quartz of the very hardest type; slime trouble was ever present and was never conquered, although the largest fixed Linkenbach tables I had ever seen had been put into commission to save the silver-lead in the slime. It was not much of a success. To crush the quartz fine enough to liberate the galena so that a 60% lead product could be made meant enormous losses, hence hand-sorting was pushed to the limit and a jig and table product sold running high in silica.

So that did not last long?

It did. The English people struggled along for about three years with it, when a clever Welshman, one Henry E. Fry, managed to sell it to the French, who operated it for several more years; but I doubt if anyone made it pay. I was in the midst of my work improving the plant when I was offered the position of manager of the La Plata smelter at Leadville, succeeding William Hanson.

He was a man of high character, I knew him well. He died in San Francisco in February last, having been for many years the manager of the California Wine Association. When did you succeed him, Mr. Argall?

In March, 1887.

What was the condition of the smelting business in Colorado at that time?

Very bad indeed; keen competition between the valley smelters and those at Leadville, and not ore enough to go around. Sulphide ores were coming in strong and the La Plata had no roasters, the blast-furnaces were small and obsolete, ore and charges were all handled by shovel and wheelbarrow. A large custom business was being handled at a loss. I piloted the old smelter along for a couple of months and, having worked out the smelting conditions carefully, I cabled my company to either furnish $250,000 to re-build the furnaces, put in roasters, and generally modernize the plant or go out of business. The conditions were such that I could only promise 10% net earnings on the new investment, not on the entire capital. I confess to a feeling of relief when the directors decided to close-down the smelter and cut their loss; nevertheless the night we blew down the furnaces was a trying one for me. It seemed like a metallurgical funeral. I patroled the dump the whole night long, wondering if I had terminated a great industry that in other hands might have been profitable, or if I had

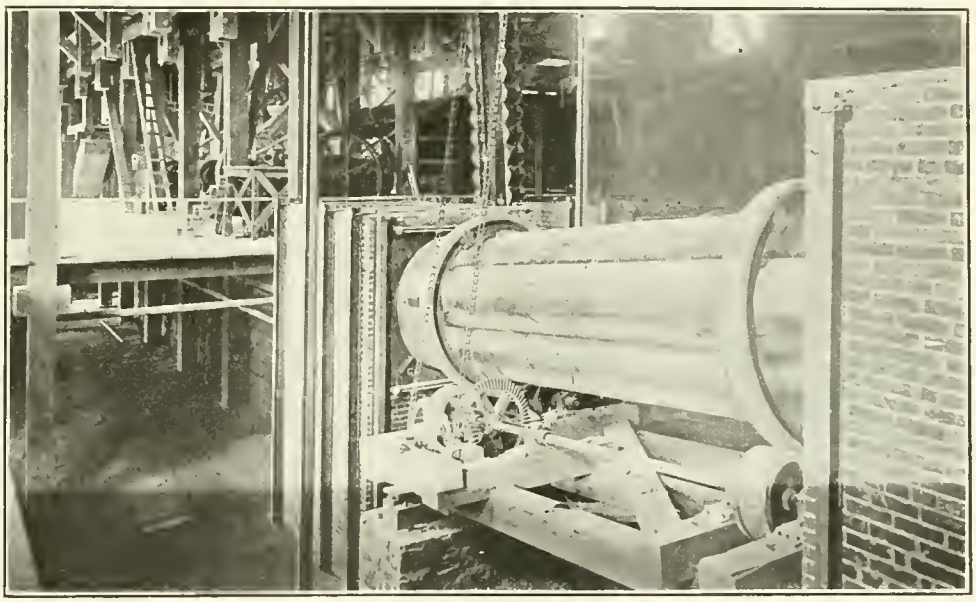
rightly advised my company. A few days later this depression passed away with the full conviction that I had taken the proper course, and I have never since regretted my action. In the course of a few years other and better equipped Leadville smelters went out of business and for years past there has been but one smelter at Leadville.

The survival of the fittest?

Undoubtedly, the largest, most modern, and best plant survived, the Arkansas Valley plant now operated by the American Smelting & Refining Co.

What became of the La Plata smelter?

I sold it to D. H. Moffat and associates. Pyritic smelting was introduced under the direction of W. L. Austin and was successfully continued under the management of the late Franklin Ballou, for several years. I had an opportunity of following the results during the trial-runs. The dust-loss at first was enormous; I was called in consultation, and designed dust-flues and condensing-towers in which the fume was washed with water, and thereafter the plant operated at considerable profit. Later, in association with Mr. Austin, I endeavored, without success, to introduce pyritic smelting elsewhere in Colorado. The La Plata smelter, partly re-built and enlarged, was afterward purchased by the American Smelting & Refining Co., and dismantled.



FURNACE IN WHICH THE FIRST TELLURIDE ROASTING WAS CONDUCTED.

It was in 1887, if I remember correctly, that you examined the Rathjen mine in Calaveras county, California, and were good enough to give me my first job as manager?

You refer to the Union Gold. Yes, I remember quite distinctly examining that property and later placing you in charge there, but the rest has passed like a dream, I can scarcely recall the developments.

When did you first become acquainted with cyanidation?

After leaving Leadville I had my first dip into the cyanide process. I had of course heard and read much about it, but for some time I considered it one of the humbugs. It was in the hands of people who did not inspire confidence, and who advertised the requirements of the process as a few old tubs, some mill-tailing, a chunk or two of cyanide, and a handful of zinc shavings. Strange to say, you yourself were the first man to place in my hands actual results obtained from the treatment of sulphide ores in Arizona.

I had quite forgotten that. The results to which you refer were those obtained on a pyritic gold ore from the Hillside mine near Prescott, then being worked by a flamboyant person called H. H. Warner, of 'Safe Cure' fame. But, Mr. Argall, you became connected with the MacArthur-Forrest people, did you not?

Yes, when the late Thomas W. Goad obtained the management of the American MacArthur-Forrest Co., he virtually forced me to act in the capacity of consulting metallurgist to that company. My first task was to rectify the failure of the first plant erected in the Black Hills; I can't recall the name of the mill but it was built at Deadwood by men from the Hill City tin mines. I believe it was in the winter of 1903. The ore could not be leached, because dust and sand were treated together in the tanks and there was too much dust. Those in charge had imported a patent pulverizer from Grenoble, France, believing slime—I should say "fine dust," for it was a dry-crushing machine—essential to good extraction. I had rolls substituted for the pulverizers, and with a few other changes, the plant operated successfully. However, I reached the conclusion that slime and sand should be treated separately, so I designed a special machine for separating the dust from the sand in dry crushing, and used V-boxes to effect the same object in wet crushing.

What was the name of the dust-separating machine?

It had no particular name, but I patented it in 1904; also crushing in alkaline solutions, separating the slime or dust from the sand and treating each separately. The dust-separator has since been widely used in Western Australia and elsewhere.

You anticipated what later became standard practice, but how did you treat the dust?

This was my practice in 1894: the dust was moistened and run through a briquetting machine, the bricks stacked, dried, and roasted in the same way as common

building-brick are made, then broken up and cyanided. The extraction obtained from the roasted brick was so very much better than that obtained from the sand, that it lead to an investigation which subsequently caused me to introduce roasting as a preliminary step to cyanidation. The experiment made on the dust from Deadwood ore gave extractions of 96 to 98%, and those on Cripple Creek ores yielded similar results.

The briquetting and roasting had the effect of giving you a porous material, I suppose?

Yes, and setting free the gold from tellurium; the bricks were so porous that I have often obtained 90% extraction from an unbroken brick.

When did you come to Cripple Creek?

In January 1894, to investigate the failure of the first cyanide plant in that district, afterward called the Brodie mill. Here the trouble was precisely similar to that at Deadwood. The charges in the tanks could scarcely be wetted, there was so much talc and clay in the dry-crushed ore. I pointed out the cause of the trouble and rectified it when enlarging the plant, which operated successfully for a year or two and was again enlarged.

What was the capacity of the Brodie mill in 1894, *and what was the treatment charge at that date?*

I left the Brodie mill with a capacity of 25 tons per day. The treatment charge on ounce ore was $15 per ton and we needed every cent of it.

You next built the Metallic works at Florence, I presume?

Yes, that was my next effort. The Moffat interests were building the Florence & Cripple Creek railroad and desired to have a large reduction plant near its terminal. I was sent for and found the directors prejudiced against cyanidation, because "the ore would not leach." On the following day, I made a stack of briquettes in a cupel-mold from the slime of Cripple Creek ore, roasted them, and repaired to the First National Bank with a pocketful of the roasted cupels, a small plate, and a bottle of water. I poured water on the plate and set the cupels in it; in a few minutes the water was all soaked up by the briquettes and I added more; when the water rose to the rim of the briquettes and began to fill the bowls, the directors were satisfied, and a week later the Metallic Extraction Co. was incorporated, and by June 1895 we were treating 3000 tons of ore per month.

That was the first large custom plant to treat Cripple Creek ore by cyanidation, was it not?

Yes.

How much of the ore purchased at that time underwent briquetting?

From 15 to 20%, depending, of course, on the crushing qualities of the ore, or the amount of clay or talc in it.

When did you begin roasting Cripple Creek ores?

During the winter of 1895, I modified one of my multitubular driers and roasted and leached several lots of 25 tons each. We next purchased a Ropp roasting furnace, the invention of Baron Alfred de Ropp, formerly manager of the Selby smelter. I believe ours was the first 'Ropp' used outside Selby; at any rate, it was the first in Colorado. Afterward I used multitubular roasters of my own design. We then purchased all the oxidized ores available and treated them direct, but the recovery of gold from the roasted product was so superior that the roasting facilities were rapidly increased, and by the close of 1897 we had a capacity of 10,000 tons per month. This was a pioneer plant in the direct treatment of sulpho-telluride ores. Engineers and metallurgists came from various countries to study our methods, more particularly the roasting feature. We had several visitors from Kalgoorlie, notably from the Great Boulder Perseverance mine.

But you modified this method later?

By the time the roasting process was fully developed, it became apparent that we were placing the cart before the horse. In roasting the telluride, coarse gold, in shots and grains, was formed commensurate with the size of the telluride particles in the feed, pieces often too large to be soluble in the time available for the leaching process; to avoid large particles we crushed finer, also placed riffles in the tailing-sluice. These riffles were very effective in collecting the 'metallics' and also some of the unroasted sulpho-tellurides, but obviously the better method under our conditions was to grind still finer; that resulted in more dust, an enlarged bag-house, and general increase in the treatment cost. I then jumped experimentally to the other extreme, with the object of making all the coarse gold possible during the roasting process and recover this coarse gold by amalgamation. Cripple Creek ore at that time contained about 2% sulphur, and I was able to make good extractions on 1-inch roasted cubes, but found that ore crushed to pass ½-in. round-hole screen when roasted gave almost perfect extractions by amalgamation and cyanide. Several tests on 5-ton lots were placed before the directors and a complete new plant decided on, embodying these features: crushing to pass ¼-in. round hole, roasting the ore at that size, fine crushing, and amalgamating the roasted ore in Chilean mills using weak cyanide solutions in place of water. Drying of the ore was eliminated, also dry-crushing and dust-loss, hence a bag-house was not required. A site for the new plant was chosen at Canon City and a branch of the Florence & Cripple Creek railroad was built to Canon City to accommodate the new plant.

In what year?

I believe work was begun on the branch in 1898 or early in 1899, but was suspended when the Moffat interests optioned their railway and the Metallic plant to those controlling the Midland Terminal railway, a rival line for Cripple Creek traffic.

Was the option taken up?

Yes, and the Metallic works passed into other hands, but I remained in charge until the close of 1900, in ful-

fillment of my contract. The new people naturally did not care to build a new works and scrap or remove the plant they had just purchased for $600,000, so I refused to renew my contract.

Was it your purpose to scrap the Metallic plant?

Not exactly; the directors decided to erect a new plant at Canon City of 15,000 tons per month capacity, and when that was in successful operation, remove the machinery from the Metallic, and ultimately have a plant capacity of 25,000 tons per month under the new process at Canon City at an estimated treatment cost 50% below our cost at the Metallic plant.

What was the cost of treating a ton of ore in the Metallic plant?

About $3.50, all-roasting, at 9000 tons monthly capacity.

Chihuahua, and other Mexican mines, the ores of which I tested before outlining their proper treatment. I urged consistently that cyanide was bound to win as against chlorination in the treatment of Cripple Creek ores; cyaniding was so much simpler, so much cheaper, and with the many improvements introduced throughout the vast regions tributary to cyanidation, the process would yearly become simpler, more certain, and cheaper.

Did you make any bromination experiments?

Only on a laboratory scale. The late H. R. Cassel was the bromine protagonist and a most remarkable man. I first met him in 1887 when he was building the Nelly Bly mill to exploit his bromine process in Boulder county. We next met at the Telluride mill, at Colorado City, afterward called the Golden Cycle mill. This was erected to treat Cripple Creek ores by leaching with bromine solution in open vats, displacing the bromine

THE METALLIC WORKS AT FLORENCE, COLORADO, 1896.

How did you treat the 'metallics' caught in the sluice?

We first sold the heads to the smelters and sent the lower-grade back through the plant. Then I put in a small Chilean mill, amalgamating plates, etc., and ground fine, amalgamating the entire product. In this test-mill I also made my first experiments in amalgamating and cyaniding the coarse roasted Cripple Creek ore.

What became of the Metallic mill?

It was operated for about six months after I left; the new owners helped to form the mill 'trust' or 'combine,' in which chlorination was the dominant feature. The Metallic mill was sold to this group, closed-down, took fire while being dismantled in 1904, and burned to the ground. Financial affairs often upset the best-laid plans of metallurgists, so through financial backing, and not because of merit, the chlorination process reigned supreme for about six years.

But that did not end your connection with cyanidation, Mr. Argall?

No, I maintained my interest in cyanidation by frequent contributions to the technical press, by lectures, and in consultation work; such as the Dolores mine, in the filtrate with chlorine and recovering the bromine for re-use. The evolution was from open vats to covered vats, covered vats to revolving barrels similar to those used at that time in the chlorination mills, and, lastly, to straight chlorination in the revolving barrels. J. T. Milliken, of St. Louis, having secured an option on a block of Telluride Reduction Co. stock, employed me to look into the process at the time of the trial run. I pointed out in a letter what I considered the weak points and advised him to not exercise his option. He followed my advice. A few years later, 1904, the plant went into the hands of a receiver and at Goldfield, Nevada, an urgent telegram reached me, requesting that I come at once to New York for a consultation. I did, and found that Mr. Milliken had handed my letter on the process to the company; that it had been discovered by the receiver, and found a fairly accurate forecast of the shortcomings of the Cassel bromine process, so much so that the directors desired my advice. I examined and reported on the plant, placed a valuation on it, and advised that cyanidation be introduced. The large shareholders held some meetings and finally decided that they had had enough. I believe the money lost in that ven-

ture was about $800,000. Toward the close of operations Mr. Cassel was working on an electro-chlorination scheme somewhat similar to the Clerici-Pelatan, in which salt was electrolized in cyanide solution, but the apparatus had not been set up.

But you re-designed and greatly enlarged this mill later?

Yes, in 1906-7, after Mr. Milliken had purchased the old Telluride mill, I had the opportunity of introducing the methods I had intended using at Canon City in 1899 with, of course, such improvements as had developed in the interval. The old roaster-building was enlarged, a new sampling and fine-crushing mill added also a large leaching plant and storage-bins. The scheme was to crush the ore without drying, to somewhat less than ¼ inch, roasting, crushing fine, and amalgamating in Chilean mills; separating the slime from the sand and treating each separately. I never operated the plant, however. After a set-back through fire the plant gradually forged to the front and drove chlorination from the field, so that for the last three years cyanidation reigned supreme in the treatment of Cripple Creek ores.

What is the present capacity of the Golden Cycle mill and the cost of treatment?

The mill is reported to be treating about 40,000 tons per month and is paying $30,000 per month in dividends on a capital of $1,500,000 or 24% per annum. The total gold production is in the neighborhood of $50,000,000, five times the total production of the Metallic Extraction Company. I have not seen any recent treatment cost.

What was your next important work?

I was very busy between 1903 and 1907, apart from the work noted, traveling extensively in Mexico on consultation work. One case of importance was at a cyanide plant where old tailing would neither leach, filter in a press, or settle for a decantation. It proved to be a surface-tension phenomenon, cured by the addition of 2 pounds of sulphuric acid per ton of dry slime. An agitated charge, after 12 hours standing, gave less than 1 inch of clear solution; after acid was added, over six feet of clear solution could be drawn off under like conditions of time and charge. That was one of my best day's work; on leaving, I told the superintendent to cut down the acid after everything was running nicely; a year later I wrote to know how much acid he was using, he replied "Two pounds per ton of slime. I tried to reduce the acid on various occasions, but the settling rate decreased, as did also the extraction." So in this case of arrastra tailing, acid increased the extraction and made decantation possible.

In the fall of 1905 I had charge of the field-work of the Zinc Commission appointed by the Government of Canada to investigate the zinc resources of British Columbia and test the ores to determine the best commercial process for beneficiating them. It took the greater part of 1906 to complete these ore-tests and prepare the report and maps. That work has been well received, and may be said to have stood the test of time, though the field-work was greatly rushed in an endeavor to get it finished before snow-fall.

When and how did you become connected with Stratton's Independence?

In November 1906, while in the Arizona desert, I received a cablegram from London offering me the position of consulting engineer, with special request to make prompt investigation of the best means for treating the big dumps at Stratton's Independence mine, at Cripple Creek.

Had any previous work been done on the dump?

Yes, Cassel had built a small testing-plant, introduced his electro-cyanide process and the Cassel filter process, in which latter the old Stratton's Independence company had an interest. Godfrey Doveton and others investigated this, the last of the Cassel processes, and turned it down. Over $60,000 had been spent and nothing particular accomplished, except sampling the dump, hence the directors were very anxious for me to get busy and report. I started concentration tests in January 1907, and determined the recovery available by that method. Next, the recovery by cyanide from the tailing. I then fell back on long years of experience in arriving at the cost of the various operations, such as mining the ore from the dump, delivery of it to the mill, crushing, concentrating, cyaniding, treating the concentrate, and marketing the bullion. I cabled my results in March 1907, claiming a working cost of $1.52 on a basis of milling 10,000 tons per month. This, mind you, at a time when custom mills were charging $5.50 to treat a ton of low-grade ore. Of course, I laid myself open to criticism by stating that such ore could be treated on the mine for about one-fourth that cost, and I certainly received my full share of attention from the people that fail to advance with the times. It was a new problem, anyhow; it cost us $3.50 to treat a ton of ore at the Metallic works; here a profit had to be made from $3 ore.

I know you worked within your estimate for some years, but how did cost and extraction average over the milling period?

The milling of 671,665 tons in 6 years shows an average treatment cost per ton of $1.5138, and an average extraction of 74.57%, against my estimate of $1.52 and laboratory extraction of 74.22%.

The agreement between the figures is almost uncanny?

Perhaps it's a coincidence; the cost during the six years varied with the tonnage, the lowest annual cost being $1.38 on 133,875 tons; the highest, $1.79 on 68,711 tons.

You have had a long and active experience in the metallurgy of Cripple Creek ores?

It has been my privilege to see the cost of treating these ores by wet methods, reduced from $15 per ton in 1893 to $3.50 in 1898 and to $1.38 in 1913.

Have you had anything to do with flotation?

Yes, quite a little. I was familiar with Henry E. Wood's experiments and had read about the Elmore vacuum process. In 1907 I had an Elmore expert test a line of samples from the Independence dump. The re-

sults were very erratic and on the whole little better than water concentration gave. I had sufficient tests made to lead me to the conclusion that the Elmore process was of no use in treating that particular dump, which contained much oxidized stuff; furthermore, cyanide treatment of the flotation tailing was equally uncertain and invariably low. At first I attributed poor extraction to the acid, and later to oil, which I concluded interfered with the solvent action of the cyanide; so I dropped the matter in disgust.

Just what recovery did you obtain by the Elmore vacuum-oil flotation process?

Taking the more regular of the tests:

Ore reduced to 20 mesh 34% recovery
" " " 40 " 50 "
" " " 60 " 51 "

In the same year, 1907, I was investigating the ores of the Graphic mine, at Magdalena, in New Mexico, a very bad mixture of sulphides and iron oxides. Again I had tests made by the Elmore vacuum process, and the results were extremely erratic, but two tests gave a concentrate exceeding 40% zinc, one a 46% zinc concentrate, the highest-grade product secured up to that time. Several other tests gave only a 30 to 40% zinc concentrate with a very poor recovery. It appeared that the specularite in the ore became oiled under average conditions in the vacuum process and floated readily; on the other hand, much of the zinc failed to oil; consequently the majority of the tests gave unfavorable results. Still I believed that flotation offered the best solution, and advised the company to erect a small testing-plant, seven years ago.

But you have used flotation since?

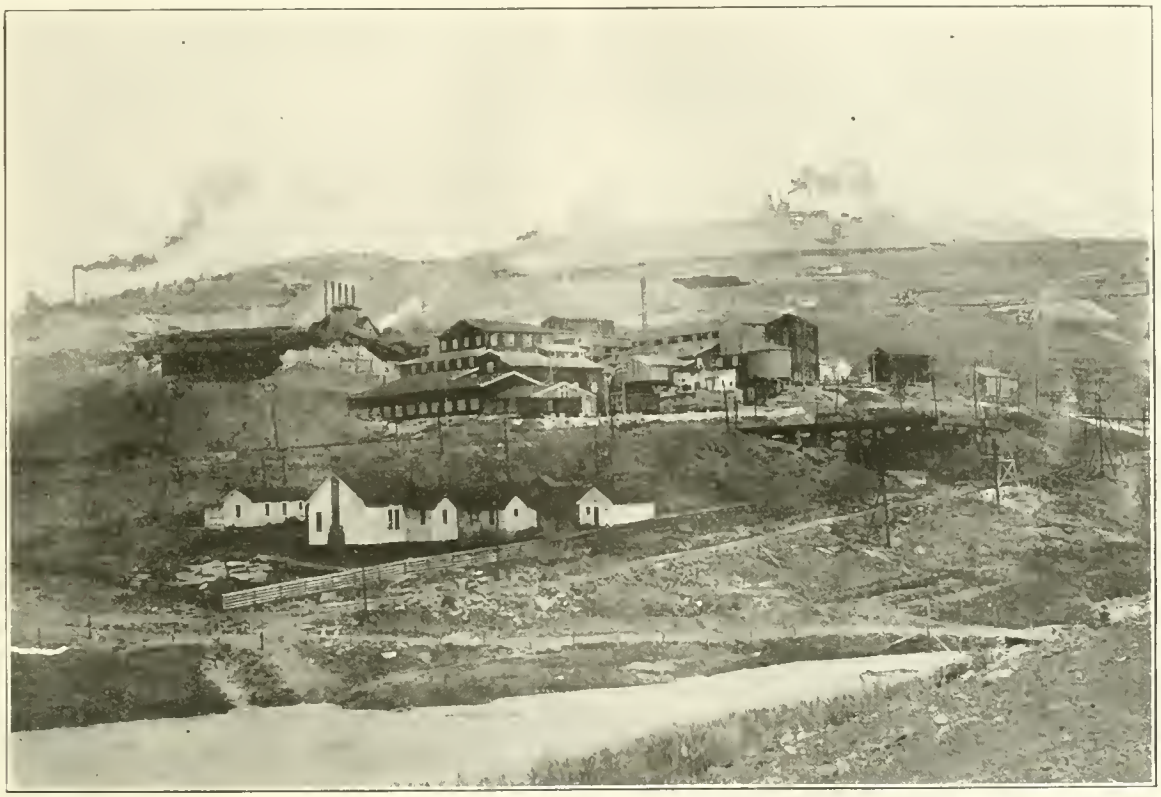
Certainly, we have been floating these very ores for almost three years now, and I assure you we have one of the most complicated mixtures ever encountered, consisting of sphalerite, intimately blended with magnetite, pyrite, pyrrhotite, specularite, galenite, and chalcopyrite in a lime and tremolite gangue.

What mine is it?

The old Graphic, now the property of the Ozark Smelting & Mining Company.

What phase of flotation do you employ?

Surface tension or 'film flotation,' as I prefer to call it, in distinction from the 'scum' or 'froth' that is allowed to accumulate in a thick layer by other methods.



THE INDEPENDENCE MINE AND MILL, CRIPPLE CREEK.

I understand that you use oil?

Yes, we use mineral oil, and that is, perhaps, one of the chief points of departure. We are pretty well out in the desert there and use Diesel engines for generating power, and have gotten the oil question down to the point where we use the same oil in the Diesel engine that we use in the mill for flotation purposes.

But I understood you to say that the result of the use of oil with agitation is to give a film rather than a froth?

Precisely, crude oil, or residuum, can scarcely be classed among the good froth-producers.

Do you make a froth?

No, the ore is agitated with oil and acid and presented in large open vats to a surface of briskly moving hot water, on which the oiled particles float away rapidly as

a thin film, and the unoiled particles sink. There is no froth to be seen on the vats at any time.

What becomes of the matter that sinks in the vats?

It passes to other mixers and is given a second, third, and, if necessary, fourth opportunity to oil and float.

When the mixture of ore, acid, and oil is discharged upon the surface of the hot water in the vat, the oiled mineral forms a film, I presume?

Yes, a continuous film of considerable cohesion, but very thin. I might add that owing to the intimate mixture of complex minerals we crush very fine, over 50% of the pulp will pass 200-mesh.

Which of the sulphides are found in the film on the hot water?

Mostly the sphalerite, with some pyrite. Pyrrhotite often favors sinking unless excess of oil is present.

Does that suggest that the sphalerite has a greater selectiveness for the oil than pyrrhotite?

I believe it does.

As you are crushing so finely, I presume that slime offers no obstacle to the operation of this process?

None whatever, the most marvelous recoveries are made despite the fineness of the pulp, both the highest-grade zinc and the highest recovery are obtained from *minus* 200-mesh pulp.

Can you give me any figures of actual extraction?

You scarcely expect a full answer to that question. I can, however, answer it in part without giving away any secrets. We make no recovery of zinc carbonates or oxides, but of the sulphides that are *minus* 200-mesh. Our recovery is around 95%, making a 45% zinc concentrate from 16% zinc ore in one operation. I have been astounded at the recoveries that it is possible to make from slime, by flotation methods. In slime treatment, I feel assured, the future of flotation lies.

Do I understand you to say pyrite, pyrrhotite, and other sulphides, except the zinc sulphide, sink with the gangue minerals?

I do not wish to convey that idea: pyrite is always troublesome, pyrrhotite less so, yet when the minimum amount of oil is used we do sink some of the pyrite and much of the pyrrhotite. Under certain conditions there appears to be a selective action for the sulphides in the order given. The ore is delivered from the mine to a breaking and sorting plant, where pyrite, other sulphides, and waste are sorted out as closely as possible on a picking-belt. The sorted ore is then conveyed to the mill, one mile distant over an aerial tram and the remaining sulphides treated by flotation.

Do you have to re-treat your first film-concentrate?

No, just dewater it. The concentrate-overflow from all the vats is pumped direct to an Ovoca classifier, the overflow from which consists of dilute gangue-slime, all of which will pass 200-mesh and assaying about 3% zinc, while the concentrate discharged from the screws will average about 45% zinc.

How do you remove the specularite?

By strict adherence to film flotation. In the Elmore flotation specularite was taken up with the sphalerite in the mineral 'scum' or 'froth,' perhaps on account of its high lustre. Specularite, though an oxide, is easily floated. Henry E. Wood tested the Graphic ore for me on his machine in 1907, using water only; the specularite floated beautifully, with some of the sphalerite. Mr. Wood said at the time that specularite was the only oxide he knew that would float in his process. Why we sink this mineral in our process is difficult to explain, but it is done.

What do you call the process?

The Ozark Flotation Process, worked out especially for these ores, and patented by W. Sydney Stevens of Magdalena. My firm is responsible for the detailed design of the plant and general supervision of its operation.

I recall your article on the occurrence of siderite in the Leadville ore, published in the Mining and Scientific Press *of July 11 and 25, 1914; has the discovery proved of economic importance?*

There is yet no market for siderite carrying 20% manganese and 25% iron; siderite, however, is of great importance in prospecting for sulphide ores and occasionally for zinc carbonate ores, "no siderite, no sulphide" is now a recognized guide in prospecting in the White Limestone horizon.

The much debated and vexed question of the origin of the manganese in the oxidized ore, or "black iron," of Leadville is finally settled. My reference to siderite as the source of the manganese in the *Mining Magazine* of April, 1914, was not fully convincing, but the second paper 'Siderite and Sulphide' has proved incontestable; furthermore I have recently found what I call the Rosetta stone of Leadville; a piece of siderite colorless and unaltered at one end, passing into 'black iron' at the other, through the oxidation of the siderite.

Have you made further researches on what you call 'vein' siderite?

I have, and find in every case that vein siderites carry high value in manganese, specimens from Mullan, Idaho, show as much as 25% manganese in siderite associated with chalcopyrite, magnetite, and quartz. The fact I endeavored to establish, that vein siderite is invariably manganiferous, may have wide economic importance.

Mr. Argall, you are now in consulting practice in Denver. I believe your sons are following in your footsteps? By the way, when were you married?

Some few years ago I formed a partnership with two of my five sons. The two partners are Philip Henry, who is a graduate of the University of Colorado and has practised in metallurgy for several years, four years at the Selby plant, part of the time as assistant-superintendent; and George, a graduate of the Columbia School of Mines, and now general manager for the Iron Silver Mining Co. at Leadville. We are consulting engineers to the latter company, Stratton's Independence, and the

Ozark Smelting & Mining Co. I was married on August 31, 1876, in the sweet Vale of Ovoca. My wife, who died in 1903, was the daughter of Capt. George Oates, a Cornishman with a long ancestry of miners, a man to whom I am indebted for much of my early training in engineering and ethics.

You consider that our profession is still one that offers good opportunity to young men?

I consider that mining and metallurgy offer the very best opening to talented energetic young men, and the openings in the future will be far better than they have ever been in the past.

I remember that you received the gold medal of The Consolidated Gold Fields of South Africa, through the Institution of Mining & Metallurgy in 1903.

Yes, the medal and 40 guineas was unanimously awarded to me by the council of the Institution for my paper on 'Sampling and Dry Crushing in Colorado,' in other words, the mechanical treatment of ore by the dry process.

What do you consider your best achievement?

The introduction of the 8-hour working-day in Colorado mills, in the spring of 1899, at the Metallic works, without consulting my directors. It led to better work, in time, to a better class of workmen, and a greater tonnage handled per man, in a word, to the elevation of our workmen and the lowering of the working cost.

TUNGSTEN discoveries are being made in the Black Hills, South Dakota, as described in our issue of November 27. Three areas are known, the Lead-Flatiron, Tinton, and Harney Peak pegmatite districts. At the Wasp No. 2 gold mine at Flatiron the ore appears to be a replacement of dolomite at and near the top of the Cambrian quartzite; the deposits are nearly horizontal, about a foot thick, 4 or 5 ft. wide, and at times several hundred feet long. The Wasp company recently shipped 26 tons to the Crucible Steel Co. at Pittsburg; the lot was valued at $54,000. The low-grade ore has been put on a dump, for the concentration of which a plant of 25 to 30 tons daily capacity will be operated as soon as machinery arrives. The company's profit from wolframite appears likely to be larger than the net realization from its cyanide plant. The ore is fine-grained, hard, and tough, requiring grinding to not coarser than 30-mesh in order to make a good recovery. The ore is mostly wolframite, scheelite occurring only in small grains. In the Harney Peak area, wolframite and ferberite occur in quartz veins and pegmatite dikes, although so far no production has been made from the latter. The veins are generally less than a foot thick, with walls of schist, granite, or pegmatite; their direction is usually parallel with the schistosity of the wall-rock. In other localities small veins have been discovered; the quartz veins as a rule produce clean ferberite, with occasional scheelite, and since the ores contain no pyrite, tantalite, columbite, or other heavy interfering mineral, a good product is made. In the Tinton district the placer deposits yielding wolframite and scheelite are low-grade.

Metal Mining in Japan

According to a report issued recently by the Department of Agriculture and Commerce, the mining industry in Japan has in general been favored by the War.

GOLD AND SILVER. Mining of these two metals has been favored more than others. New gold mines have been recently opened, and the output from those in the province of Idzu has increased. Their ores are being sent for refining to the Kuhara Mining Co. in Hitachi province. The output of refined gold in Kushikino, in Kashima prefecture, owned by the Mitsui Mining Co. and in the Matsuoka mine, in Akita prefecture, owned by the Fujita Gumi, has also improved. The amount of gold recovered to the end of September 1915 shows an increase of 24%, compared with the amount in the corresponding period of 1914.

COPPER. Japanese copper has in the past been mostly in demand in China, but the decrease of coinage in that country in recent years caused a depression in this trade last year. The outbreak of war, however, saw the sudden growth of demand for war use toward the end of last year. Since then, the metal has been supplied to England and Russia in large quantities.

ZINC. The zinc-refining industry in Japan is of recent origin. In 1913 the Mitsui Mining Co. started zinc refining in its Miike mine, and the Osaka Zinc Co. in the Kamishima refining works, Okayama. The management has had to overcome various technical and economic difficulties to push on the work in the earlier stage, but the War has cut off the supply from Germany and Belgium, and has encouraged the new industry in Japan. The amount of refining is steadily increasing. At present, the metal is even being exported to Russia. Judged from the present conditions, it would seem possible that Japan will establish permanent independence in the supply of zinc after the restoration of peace. Besides the above mentioned refineries, there are also the Yasojima, Niigata, Takachiho, Yamaguchi, and Shikama, Hyogo. Zinc ores are supplied partly from Chosen, the coast province of Siberia, and Australia, and partly from home mines.

THE superintendent of the Mint at San Francisco, T. W. H. Shanahan, reports the following receipts for the calendar year 1915:

	Fine ounces.	Value.
Gold	5,798,686.341	$119,869,484.97
Silver	2,120,595.240	1,058,711.50

Coin, bullion, etc., on hand at close of business on December 31, 1915 was as follows:

Gold coin	$6,293,507.50
Silver coin	61,607,187.18
Minor coin	26,680.26
Checking balance Treasurer U. S.	3,721,834.94
Gold certificate bars,	176,717,272.59
Gold bullion	110,330,121.40
Silver bullion	1,174,956.67
Total	$359,871,560.54

Mining in Utah

By L. O. Howard

THE past year has seen the mining industry of Utah return to a condition as prosperous as that preceding the collapse of 1907, and announcements made near the end of the year presage even more prosperity. The development of a potash industry in Utah has been widely noted. The plant of the Mineral Products Co. at Marysvale has been producing 25 tons of potash salts daily for some time past. It has been decided to treble this capacity, and plans are being drafted for the extension of the aerial tramway to bring the product of the mine nearer the mill, there being a wagon-haul of about four miles from the present terminus of the tramway to the mill. It is also announced by officials of the company that some progress has been made toward the extraction of aluminum from the by-product alumina. Other possibilities suggested are the manufacture of refractory materials from the by-products of the potash extraction.

Another company, the Utah Potash Co., of which F. A. Fitzpatrick of Philadelphia is the active head, has announced its intention to erect a mill at Marysvale, and is receiving bids for an 8-mile tramway to connect mine and mill. F. K. Cameron, formerly of the U. S. Bureau of Soils, is the company's chief chemist. In addition to the holdings of these two companies there are said to be many other promising alunite veins in the district; these have been located by others.

Efforts to produce potash have not been confined to the alunite district. A strong organization is building a plant near Great Salt Lake with the expectation of recovering potash from the brine of the lake. The content of the brine in potash is so low, however, that many regard this attempt as likely to succeed only during the period of high prices. Little doubt is expressed as to the operation being profitable while war prices prevail, and it is decidedly possible that the costly experience gained during the period of high prices may enable the company to remain in business when the market again becomes normal.

The Promontory zinc district continues to maintain its excellent rate of production. Successful development has given great impetus to the search for zinc ore. It has been distinctly a poor man's opportunity. Little initial capital was required and the dividends within a year of the first development have exceeded, I believe, the money invested in the district. The Lakeview Mining Co., the principal operator, has paid dividends of over $45,000 on an original investment said to be less than $4000. Minnesota capital has recently come into the Santaquin-Nebo district, where large bodies of low-grade lead and zinc carbonate ores have been known for some time to exist, and it is likely that the coming summer will see the removal of the handicap under which this district has labored through lack of capital.

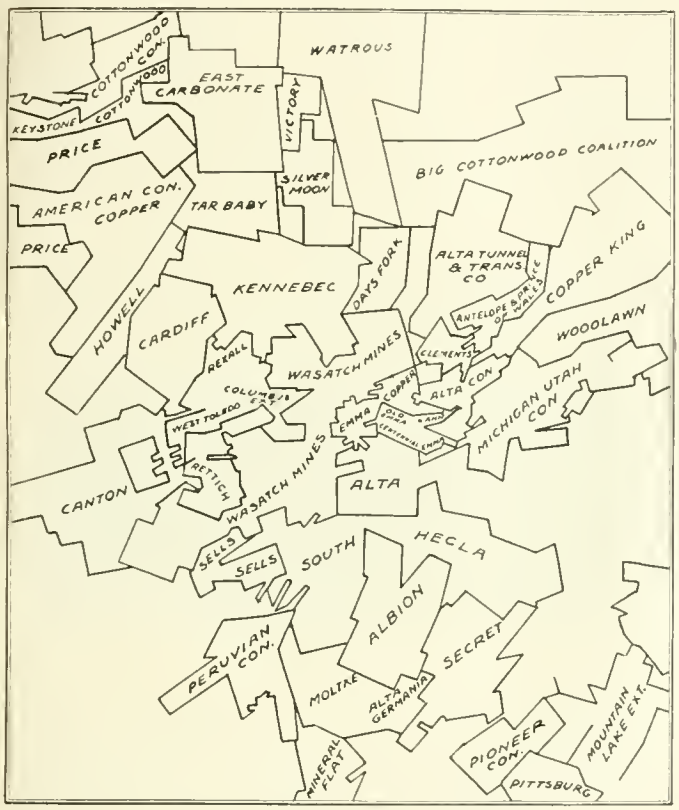
In two branches of metallurgy great advances are expected in 1916. At Murray, the American Smelting & Refining Co. has been making electrolytic zinc at the rate of about two tons per day. There is a possibility that this experiment will warrant the construction of a plant of commercial size. Much work is being done looking toward the extraction of zinc by hydro-metallurgical methods, in order to relieve the smelters of the necessity of discarding valuable zinc from their mixed lead-zinc ores, and to avoid not only this waste, but the accompanying losses in zincy slags. With the aid of flotation in the making of a high recovery of the lead and zinc sulphides, roasting in furnaces of the McDougall or Wedge type and leaching, it is expected that the zinc can be recovered as a valuable product and the residue utilized for its lead-silver content, with better results than now obtained where a lead ore high in zinc must be charged to the furnaces. The local station of the U. S. Bureau of Mines reports gratifying progress in the treatment of mixed carbonate ores also. Great advances in the metallurgy of lead and zinc are indicated in the current year.

War prices have also induced the final drafting of plans for the manufacture of sulphuric acid. A plant is to be erected to be operated in connection with the Garfield smelter, the first unit of which is to have a capacity of 100 tons of acid daily. Here, also, a loss of the past is expected to be converted into the gain of the future.

Operations in the Cottonwood districts have been greatly hampered by the heavy snow-fall of the last few weeks, but are being advanced with a vigor not seen since the early days of the districts. The output for the past year has been estimated at 25,000 tons, double that of the previous year. It is likely that this increase can be accounted for in the production of the Cardiff mine. Shipments will be increased as soon as the snow has packed enough to make hauling easier. Every little prospect has two or three men at work, either driving tunnels on contract or leasing in old workings.

On the Big Cottonwood side of the district the following companies have from two to six men working: Reeds Peak, Branberg, East Carbonate, Big Cottonwood Consolidated, Tar Baby, Price, Monte Cristo, American Con. Copper, Kennebec, Last Chance, Baker, Copper King, Swastika Copper, Woodlawn, Logger, Alta Tunnel & Transportation, Mines Development, Big Cottonwood Coalition, Giles, Alta-Cottonwood, and the Antelope and Prince of Wales lease. In Little Cottonwood the following are active, Sells, Albion, South Hecla, Alta Consolidated, West Toledo, Columbus Extension, Michigan

Utah, Emma Copper, Alta-Tiger, and Wasatch Mines. In addition the Cardiff employs about 100 men, and the Maxfield something less than half that number. Activity extends from the extreme eastern to the extreme western edge of these twin districts. One small mill is in operation jigging the old stope-fillings of the Prince of Wales, which are stated to average $8 per ton in lead and silver. Other companies are known to be planning extensive development as soon as weather conditions will permit it in the spring. Indications point to a heavy production next summer, as a result of the large amount of work



THE COTTONWOOD DISTRICT, UTAH.

being done, and the systematic expenditure of money by many companies.

This activity bids fair to extend to the adjoining American Fork district. Development work is in progress there, and more is planned. It is also certain that a publicity campaign such as was engineered for the Cottonwoods last summer is in preparation in connection with American Fork.

Owners of mining locations in Beaver county are quietly planning an energetic development for this year, and it is probable that the attention of the investing (or perhaps the editor prefers 'speculating') public will be strongly directed to this district. The entrance of the United States S. R. & M. Co. into the Fortuna district will result in well-directed exploitation of that section of Beaver county.

The Cottonwoods and American Fork districts have been made the subject of a short study by geologists of the U. S. Geological Survey, a report of which has just been issued. Comment is reserved for a later article.

The Nation's Life

In his annual report the Secretary of the Interior says: "There is an evolution in a new nation's life quite as interesting as that in the life of a man. We pass through stages of development from the simple and earlier period when food is the one thing desired into the more elaborated and complex stages where first we begin to deal with the easily handled things and later reach the point where mind has a controlling part in all that is done. The pioneer builds his cabin and turns his cattle to graze upon the unfenced wilderness. He takes his water from the stream and makes his gun serve him with food and give him protection. It is not many years, however, before he has passed from herdsman to farmer, when soil must be plowed and seeded down. At first the one-horse plow will do, and any seed. But life grows more intense —society has gathered around, new demands are created —machinery must be used, seed must be selected, soil fertilized, credit obtained, markets sought, and the life of the simple herdsman has become complicated and broad. The gay recklessness of other days gives way to constant thought. So has it been with this country. For a long time we lived off the country's obvious supplies. Later we were producers of raw materials—grains and minerals, lumber and cotton. When manufacturing began it was of the larger, coarser things, which perhaps in their turn went abroad for higher fabricating. Now, however, we have come into the full tide of modern life when we seek for greater and more varied industries, wider markets, more economical methods of production and exchange. And in such a new time direction is needed, mutual and co-ordinated effort must be set up and the more elaborate machinery of organization put into service. Thought becomes the basis of the new life—hard, close, insistent, constructive thought, illuminated by knowledge and made practical by imagination."

First cost in buying is illustrated by a story told in the interesting little monthly publication of the W. S. Tyler company of Cleveland. In a club in that city, a member of the restaurant committee, who was looking to cut costs, remarked to the steward that it seemed extravagant to buy domino sugar of which each lump was individually wrapped in paper. "Yes, but it is quite a saving in our sugar bill," said the steward, "in spite of the fact that it costs 10% more. In the first place, when we bought unwrapped cube sugar, there was always 10 to 20 pounds that became granulated in the bottom of the barrel, and which could only be used for cooking—at cube-sugar prices. Then, there are many cubes wasted on the table and these have to be thrown away by reason of being stained when taken out of the bowl with a wet coffee-spoon. Then, still another and very large economy in wrapped sugar is the fact that people do not use so much sugar when they have to go to the trouble of taking off the papers."

The Chuquicamata Mine

By Pope Yeatman

*The Chuquicamata mine is situated at Chuquicamata, in the great arid region of northern Chile. It is, as regards tonnage and content of its valuable metal, the greatest known copper deposit in the world. It is unique in that its principal mineral, brochantite, is mined on a commercial scale in no other locality. Labor conditions are good. The Chileans are strong and active and make good miners and mechanics.

The ore outcrops over a length of about 8000 ft. and an average width of about 554 ft. The ore deposit represents a section of great dynamic disturbance, which allowed the deposition later of primary metallic minerals, brought in by solutions from below. Taking a cross-section through the deposit, five zones are represented, which, beginning at the surface, are as follows:

1. Leached zone or capping.

2. Oxidized ore or zone of brochantite, carrying oxidized minerals of copper.

3. Mixed oxide and secondary sulphide minerals, representing the transition between the oxide and sulphide ores.

4. Secondarily enriched sulphide zone.

5. Primary ore. This is represented by iron pyrite, chalcopyrite, enargite, and bornite, which were deposited from hot solutions introduced from below.

Drill-holes and shafts have so far shown a thickness of 361.3 ft. of oxidized ore, 116.3 ft. of mixed oxide and sulphide ore, and 58.6 ft. of straight sulphide ore.

The value of the deposit is due primarily to secondary minerals, resulting in the concentration of values and in oxidation of such secondaries as sulphate. These latter, instead of being removed entirely, owing to the remarkable aridity of the district, were not carried off by surface water, and hence produced, even in the zone of oxidation, commercial ore.

Ore reserves, as of April 25, 1915, amounted to over 300,000,000 tons, containing better than 2% copper. Mining is done by means of steam-shovels. They load into broad-gauge cars of 60 tons capacity, which will transport the ore to the plant.

The ore is crushed to a maximum size of one-half inch and leached in vats of about 10,000 tons capacity each. Copper in the solutions from the dechloridizers is deposited electrolytically and the cathodes melted into commercial bars.

Power for operating the machinery at the plant and for the electrolytic deposition of copper is generated at Tocopilla, in a plant of 40,000 kilowat capacity. The generators are operated by steam-turbines, and the current is conducted from Tocopilla to Chuquicamata over a transmission line 140 kilometres in length, carrying a current of 110,000 volts.

*Abstract of paper read before the Pan-American Scientific Congress, Washington, December 1915.

Preparation of Tungstic Metals

*The metal is prepared in two forms, namely powder and ferro-tungsten alloy. Much discussion has arisen regarding their respective advantages, especially with reference to the relative waste incurred during introduction of each form into the steel bath. Apparently, no decision has been reached, since both forms are manufactured, although about 85% of the tungsten is made into ferro-alloy. Powdered tungsten is fed into the bath by means of an enclosure in steel tubes, in order to prevent oxidation of the tungsten. The manufacture of powdered tungsten first demands a preparation of tungstic trioxide (WO_3) from the ore. This is accomplished by grinding the concentrate very fine in tube-mills, followed by fusion on a reverberatory hearth with sodium carbonate in the form of soda-ash and a small proportion of sodium nitrate. The hand-rabbled mass is drawn, crushed, and leached with hot water. The sodium tungstate so formed is readily soluble, while the iron remains as insoluble ferric oxide and the silica as insoluble sodium silicate. Loss from formation of insoluble sodium meta-tungstate may be largely overcome by treatment of the insoluble residue with a solution of caustic soda, which transforms the 'meta' into the normal tungstate. Indeed, a method is published whereby the mineral tungstate is purposely converted by careful addition of acid into the insoluble meta-tungstate, which is then filtered, washed, and decomposed by hydrochloric acid. The rather concentrated solution containing the sodium tungstate is heated and poured into hydrochloric acid, which precipitates the yellow tungstic acid. The latter is filtered and washed in acid-proof presses, and then dried.

Reduction of the oxide is accomplished by mixing intimately some pure form of carbon, such as charcoal or petroleum coke, and the charge is pressed into graphite crucibles, which are heated in coke furnaces to a high temperature. A rather coarse, steel-gray dense tungsten results, which, with care, may have its carbon contents kept within 1%.

Ferro-tungsten, the second product, is made mostly from the concentrate direct by electric-furnace treatment. It contains from 50 to 80% tungsten. Many different reducing materials are recommended. Carbon, in the form of coke, is the common reducing agent. Lime and silica are added to form a suitable slag, and sometimes fluorspar is added to aid liquifaction. Hematite is used subsequently as a de-carbonizer. Other procedures call for silicon, ferro-silicon, aluminum, and even titanium as agents to reduce the carbon contents of the metal.

*Abstract from paper by Herman Fleck before the Colorado Scientific Society.

BAGDAD, which is just now in the public eye, was once the centre of the known world and a city of over two million people, ranking in size with Paris or Chicago. Bagdad has now about a hundred thousand inhabitants.

Flotation in Cuba

WE are indebted to Mr. Benjamin B. Lawrence for the following notes.

The Cuba Copper Co., operating the old Cobre mine near Santiago in Cuba, was among the first to experiment with flotation, using the methods introduced by the Minerals Separation company. A little over two years ago an experimental plant with a capacity of 50 tons was erected, and as a result of the experience gained, a 600-ton plant was put into operation and has been running since March 1914.

The development of the Minerals Separation process has been so rapid that it has been difficult to keep track of the many improvements, largely mechanical, which are constantly being made. One distinguishing feature of the process is the necessity for adapting it to the particular class of ore to be treated. In the case of the

EL COBRE MINE AND MILL.

Cobre the problem is complicated. In the upper workings the ore is largely oxidized. With depth we have a good deal of semi-oxidized or tarnished ore, while in our deeper workings, we have the untarnished chalcopyrite, which, in combination with pyrite, forms the bulk of the material that the mill is now treating.

The treatment of tarnished ore has been difficult, or rather, the mixture of tarnished with unaltered ore. Variations in the character of the ore and the difficulty of obtaining uniform composition have aggravated our troubles. We have, however, succeeded in solving most of our difficulties, as the results given by Edward H. Emerson, the manager, will show. Under his direction the process has developed into a pronounced success. Mr. Emerson describes the treatment of the ore briefly as follows:

"The ore is crushed dry by rolls, screened through 8-mesh and conveyed to the storage-bin. Four Hardinge and two ordinary tube-mills are fed from the storage-bin by individual Challenge feeders to insure equal distribution of feed. Each is fitted with an electric alarm to give warning the moment anything goes wrong. It is interesting to note that one man's life has been saved by these signals. The man fell into the storage-bin and blocked a feeder. He was taken out and resuscitated with great difficulty. Failure of instant notification would have cost his life. However, the main object is to insure regular feed, as the ratio of oil to ore is most important. Cresylic acid, carbolic acid, Mexican crude, and light asphalt oil are fed into the tube-mills by special machines. Grinding is done on a thick pulp, 25 to 30% moisture, until 65% will pass 60-mesh. The pulp goes to the M. S. box without classification or re-grinding. Fourteen stirrers with 13 spitz-boxes are used. Direct concentrate is taken from as many boxes as show a good concentrate, the poorer froth being returned to the first box. Number of boxes treated varies with this and is changed by the operator who judges by eye. All the coarse tailing is roughed over Wilfleys to recover the coarse pyrite carrying copper. Caustic soda and fuel-oil are added as needed in the stirring-boxes. The various concentrates go to the classifier, the coarser product passing direct to the bins with about 8% moisture. The overflow is thickened and drained by an Oliver filter, giving about 20% moisture. The plant handles 600 tons per day and gives about 85% extraction of the insoluble copper in a 3% feed. It is interesting to note that with El Cobre ores using a cold neutral solution wood-products have not given any satisfaction. The concentrate carries 16% copper, 35% iron, 40% sulphur, and 9% silica."

Now that we have finally succeeded in unwatering the Cobre mine, we find that the old workings reach to a depth of 1120 ft. The mine had been under water for some 80 years, and the final unwatering was completed in April of this year. The work was made doubly difficult by the underhand stoping of the earlier operators. The old stopes in the lower workings contained a large quantity of silt, and the tapping of these stopes resulted in a flow of fine mud (which, by the way, we suspect of being a precipitate), that greatly aggravated the danger of the unwatering of the mine. The final completion of this task, which has been in progress since 1907, is a great tribute to the skill of the engineer and manager, Mr. Emerson.

NICARAGUA has an area of 49,200 square miles, which is greater than that of Pennsylvania, and a population of 600,000, of which 40,000 is in Managua, the capital. The Panama Canal has helped transportation by allowing coast-to-coast trade, the country having both a Caribbean and a Pacific shore; and it is hoped that channelling and dredging of the rivers will be undertaken to alleviate still further the serious lack of communication. Nicaragua has suffered from being exploited by unscrupulous politicians and adventurers. A third of the foreign trade is with the United States, and 51% of the stock of the National Bank of Nicaragua is held by Americans. Monetary conditions have been bad for years but are improving.

WASHINGTON's production of coal has grown gradually from 5374 tons in 1860 to 3,877,891 tons in 1913. California oil is hurting the coal business of Washington. The counties of Kittitas, King, and Pierce in west-central Washington contain important mines.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

EDUCATION is a fundamental of the safety-first movement.

TUNGSTEN is used for phonographic record needles, spark plugs, contacts, and X-ray targets, as well as for tool-steel.

PENTLANDITE is a mineral occurring in the Worthington mine, Sudbury district, Ontario, and consists of 30.68% iron, 34.48% nickel, 1.28% cobalt, and 32.74% sulphur.

JAW-CRUSHERS are not so satisfactory as gyratories when the rock fed them consists of flat slabs, these dropping straight through the jaws. This is an experience in Western Australia.

WATER-HOLDING TREES and plants in the Panama Canal zone have been found to be breeding places for mosquitoes. One banana tree had five pockets, some holding several gallons of water. Such trees are to be destroyed.

LABORATORY PORCELAIN, used in ignition work, may be reliably marked by a very dilute solution of cobalt nitrate. The utensil is warmed and the mark made. This is heated strongly for a few minutes, resulting in a black mark.

GOLD recovered from 11,000,000 tons of silicious ores treated in the United States in 1914 averaged $5.53 per ton. The average recovery of gold per ton from the Alaskan quartz mines was $2.78, from California $5.46, from South Dakota $3.63.

PLATINUM is now worth over $80 per ounce. A great deal of the metal is used in incandescent lamps. B. E. Eldred of the General Electric Co. has devised a combination of nickel-steel, a jacket of copper, and a jacket of platinum as a substitute for all platinum.

TESTS between ordinary carbon-steel and tungsten-steel tools in a lathe showed that the former failed at a cutting speed of 15 ft. per minute, while the latter withstood 90 ft., its edge becoming dull red in diffused daylight. High-speed tool steel contains 5 to 17% tungsten, 0.15 to 0.35% manganese, 1 to 3.5% chromium, and 0.4 to 0.85% carbon.

IF the front wheels of a steam-shovel are off of the track, fill the dipper with rock or other heavy material, loosen up one jack-arm and swing the dipper over this side. This will raise the other side of the shovel. Put a number of men on the up-side jack, and tighten it down as hard as possible. Swing dipper over high side, and screw down loose-side jack. Continue this operation until the shovel is off the centre-bearing. If there is a key in the king-bolt, the trucks will be raised off the track. If the rear trucks are derailed, lay blocks in usual manner in order to assist the wheels to climb on the rails. If this is unsuccessful, drop the dipper and boost by means of the thrusting-engines.

REMOVAL of broken ore from stopes on veins, such as at the Rand, having dips from 25 to 33°, is considered very inefficient by M. Weinbren. This is especially so when kaffir labor is employed shoveling the ore, regulation and supervision being difficult. If excessive shoveling can be eliminated, the efficiency will be greater. To this end a new system was devised. A permanent line of chutes was laid down at a safe distance from the stope faces. The chutes were well anchored. A water tap was fitted at the top of each chute-line. Tracks of 12-in. gauge were laid down every 50 ft. along the dip of the stopes, and running from the faces to the chutes. A special ore-car was designed, having a capacity of five cubic feet. It was 18 in. above the rails, and cost $12. The number of shovelers was reduced by 50%. Several advantages are claimed for this system, including the aid of gravity and better supervision.

ALLOYS possess properties not combined in any single metal. Practical substitutes for gold, platinum, and other precious metals are not yet satisfactory in the form of alloys, yet it is hoped to find something, according to F. A. Fahrenwald, in Bulletin 109 of the A. I. M. E. Experiments proved that: (1) Metals or alloys of metals outside of the precious-metal groups, are unsuitable as substitutes for platinum. The gold and silver alloys of palladium have been found to be excellent substitutes for platinum in its softer forms, and while not so chemically resistant, fill all requirements where conditions are not too rigid. (2) Except in two respects, pure ductile tungsten, and, to a lesser degree, molybdenum, meet all of the specifications of a practical substitute for platinum and its alloys. These two defects are its ease of oxidation, and the difficulty with which it can be soldered; and they have been overcome by coating with a precious metal or alloy, the resultant material being in many ways far superior to platinum or its alloys. This material has met with instant demand, is in many cases replacing the best platinum-iridium alloys, and permits the performance of work which has been impossible with the materials hitherto available. And (3) wrought tungsten and molybdenum were produced on a laboratory scale, but no success attended the attempted production of alloys of tungsten with gold and palladium; while, on the other hand, the alloys of the tungsten-molybdenum series were produced in wrought form. These operations were governed entirely by metallographic control, and their success suggests the possible application of a similar method in a treatment of such metals as iridium, tantalum, rhodium, osmium, etc., in combination with each other, or with tungsten or molybdenum, which may result in the production of alloys possessing properties far superior to those of any material now available.

REVIEW OF MINING

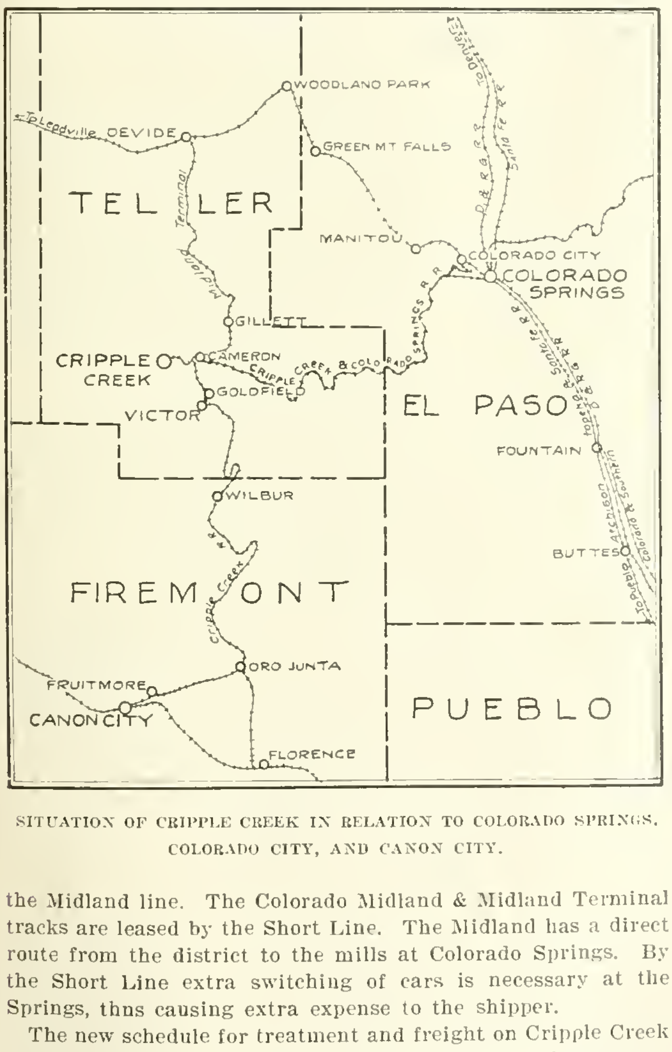
As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

Drainage-Tunnel.—Ore Transport.—A 'Dry' Town.—El Paso. —Portland.—Litigation.

The report of T. R. Countryman shows that the Roosevelt drainage-tunnel was advanced 290 ft. during December. The character of the rock traversed has not changed of late, accordingly there has been no increase in the flow of water from the portal. Toward the end of January it is expected that the main Elkton vein will be intersected. This should result in a large increase of water.

Petition has been made to the Public Utilities Commission to order the Short Line railroad to accept shipments of ore over the Midland line. The Colorado Midland & Midland Terminal tracks are leased by the Short Line. The Midland has a direct route from the district to the mills at Colorado Springs. By the Short Line extra switching of cars is necessary at the Springs, thus causing extra expense to the shipper.



Situation of Cripple Creek in relation to Colorado Springs, Colorado City, and Canon City.

The new schedule for treatment and freight on Cripple Creek district ores has been announced by the Golden Cycle company at Colorado City as follows: under and including $10 per ton, the charge is $4; over $10 and including $15 per ton, $5.25; over $15 and including $20, $6; over $20 and including $25, $6.50; over $25 and including $30, $7; over $30 and including $40, $7.50; over $40 and including $60, $8.50; over $60 and including $100, $8.75; over $100 and including $150, $9.75; over $150 and including $200, $10.75; over $200 and including $300, $12.75; and on all grades above $300, $12.75 per ton plus 1% of the value in excess of $300. It is expected that the Portland company will make a similar announcement. Both milling companies are busy engaging ore supplies and signing up contracts, and the belief is expressed in some circles that the lowering of rates and the efforts to secure contracts are due to anxiety concerning the success of the numerous flotation investigations being conducted by large mining companies.

The first day of 1916 the Cripple Creek district had no open saloons for the sale of intoxicating drinks. Owing to the prohibition laws in effect, more than 30 saloons were forced to go out of business. It is to be hoped that they will be closed for many years to come.

At the recent meeting of the directors of the Portland Gold Mining Co. the regular quarterly dividend of 3c. per share was declared, amounting to $90,000, and payable January 20. The total, including this one, is $10,267,080. The annual shareholders' meeting of the company has been called for February 21.

The December production from the El Paso mines is reported as being 2200 tons, worth $50,000.

The threatened apex suit between the El Paso company and the Katinka company has been settled out of court. The ore from the ground in dispute will be mined by lessees as formerly. All royalties paid on such ore will be equally divided between the two companies.

The building that was formerly the main office of Stratton's Independence has been moved to a point south of the railroad to make room for the new sampler which the Portland company will erect as soon as possible. Grading for foundations is already in progress. Through this sampler will pass all ores going to the Independence mill of the Portland company.

At its generating-plant at Canon City, which has a capacity of 5500 hp., the Arkansas Valley Railway, Light & Power Co. is to add 10,000 hp. The transmission-lines to Cripple Creek will be improved.

It has been published in Colorado Springs that the Vindicator company is to erect a 1000-ton flotation plant to treat dump ore at Cripple Creek.

ATOLIA, CALIFORNIA

Rush to New Tungsten Area.—Float Tungsten.—High-Grading.

Work in this important tungsten district is increasing each week. Rich 'float' ore continues to be found in numerous places adjacent to Atolia, and it seems as if the producing area would eventually cover 150 square miles of San Bernardino and Kern counties. During the two weeks following the holidays tungsten deposits were discovered about three miles west from the Rand mountains, toward Kane Springs. A regular stampede took place to the new area last week, horses, autos, and even trucks being commandeered to make the trip. The weather was fierce, and all through the night of a blinding blizzard the stampeders worked amid snow and slush to get a location somewhere near the latest tungsten discovery. Since the excitement, reports seem to verify the occurrence of a good vein of high-grade scheelite, which runs east and west, similarly to the deposits in the Atolia district. The lode seems to lie across the valley toward Jawbone canyon, the outcrop

being within three miles of the Southern Pacific line to Owens river.

A number of new leases are working adjacent to the Churchill workings west of Atolia, while the usual production of placer scheelite from the Stringer district is shipped every week to the East. Al Powell's Rand Mountain scheelite claims are being operated again by two Alaskan miners named DeBerry, who are now transporting their ore by pack train to the Johannesburg mills for reduction and concentration.

On the 'potato patch' near Atolia about 50 miners are working for the Atolia company, while individual claims adjacent to the company's are being operated for placers by their owners, or lessees, who all seem to be doing unusually well. Instances are mentioned where some are making over $100 per day in digging scheelite float.

While moving a drilling outfit from Hawes to Atolia, some float was found near Fremont peak that contained fully 60% tungsten. At the west end of the tungsten-producing belt, in the production of scheelite ore Mayhood and Fellman approximate about four tons per week. This comes from Kelsey creek, and is situated on the homestead of J. H. Robinson, who also has turned his attention to tungsten mining instead of farming.

There are several buyers of high-grade tungsten here who are paying cash for the ore, and prices are still from $1 to $4 per pound for the proper quality. 'High-graders' are keeping up their usual activity, and the appointment of a constable and justice of the peace has been found necessary to keep the community properly protected from the marauders who are indiscriminately operating throughout the district. One individual was caught on January 14 with a sack of high-grade on his shoulder and his pockets loaded as he emerged from the shaft of Churchill No. 1.

LEWISTON, MONTANA

Activity at Maiden.—Gypsum.—Coal.—Gold.—Oil.

Development and mining is active around the old district of Maiden in the Judith mountains.—The Cumberland, which contains zinc ore, is being operated under lease, after being closed for several years.—The new Spotted Horse mill erected by E. B. Coolidge is working successfully after minor changes were made; a good supply of ore continues to be developed in this famous old producer.——The Mount Grassy claims have been thoroughly sampled, and a mill is promised if sufficient profitable ore is found. Some high-grade ore has been found, but most of the assays are said to be from $6 to $10 per ton.

The Hanover Gypsum Co. has recently been incorporated. It owns 200 acres of land eight miles west of Lewistown, and within 600 ft. of both the Great Northern and the C. M. and S. P. railroads. It is proposed to build a gypsum mill next summer. The property is estimated to contain 2,000,000 tons of gypsum, and the company contemplates marketing 30,000 tons yearly. There is only one gypsum mill in Montana at present, and much gypsum for stucco and plaster is imported, so there should be a good market. O. U. Miricle and Dan R. Brown are at the head of the company.

The Cottonwood Coal Co. at Lehigh is now producing about 800 tons of coal daily. Over 200 men are employed. When present development has been completed the company will be capable of producing 3000 tons a day.

The Ruby Gulch Gold Mining Co. of Zortman, Blaine county, in the Little Rocky mountains, has purchased the steam power-plant of the old Gebo coal mine on Spring creek in South Lewistown. The plant is now being installed at the company's coal mines on the Missouri river, and will increase the capacity of the power-plant there to 1000 hp. The power is transmitted 30 miles to the 600-ton cyanide-plant of the Ruby Gulch company in the Little Rockies, which is producing gold at a rate of about $25,000 per month from low-grade ores.

Drilling for oil will soon be started in Musselshell county 10 miles south of Lewistown. Oil and gas are reported to have been found in shallow wells near Grass range east of Lewistown, and near Denton north of here, at a depth of 500 ft.

SONORA, CALIFORNIA

New Work in this Tuolumne County District.

The new five-stamp mill at the Hope mine, near Sonora, which was under temporary cover, is now housed in a substantial building. Other buildings have also been erected on the property, and a powerful gasoline engine and an air compressor installed. The Hope vein is what is commonly designated a 'pocket-milling lead,' and recently over $25,000 was taken out in a few days' work.

The opening of large orebodies in the Experimental mine, above Columbia, during recent months has been followed by the erection of a five-stamp mill. It is understood that the new mill will be started when rain has replenished the depleted water supply. The adit in which the orebodies were developed is in 2800 ft., and will have to be driven 200 ft. more to reach the shoot that made the mine famous years ago. The last two months' work with the old two-stamp mill returned approximately $4500 in gold.

Operations will shortly be resumed at the Atlas mine, near Tuttletown, which recently was bonded to a new company. Preparations for the resumption of mining activities have begun.

At the property of the Mammoth Mining Co., at Jacksonville, between 30 and 40 men are employed, and the mill is running steadily. Important surface improvements have lately been made.

Approximately 100 tons of ore from the Louisiana mine, near Tuolumne, is about to be treated at the Columbus, an adjacent property. The Louisiana, idle for many years, is being operated under lease by Richard McGhee, William Heath, and A. Layman. Good returns are expected from the ore to be milled.

The erection of new buildings and a head-frame, the installation of a hoist and other machinery, and the repairing of the collar of the shaft are among the most important things that have kept a crew of 15 or 20 men busy at the Rawhide mine the past two months. A large rotary pump and an electric motor were received last week, and it is understood that the unwatering of the mine will begin soon.

The South American Development Co., of which J. W. Mercer is general manager, has re-opened the Poison Oak mine, near Tuolumne, and development work has begun under the direction of W. H. Knowles. At present the men are driving a cross-cut from the bottom of the 300-ft. shaft. Former operators erected a five-stamp mill and crushed considerable good ore, but in the meantime development revealed no new orebodies and the mine was closed several years ago.

TORONTO, ONTARIO

Porcupine and Kirkland Lake News.—Tellurium and Platinum.

The leading Porcupine mines continue to increase their gold yields. During December the Dome produced $160,950 from 30,120 tons of ore, an average yield of $5.39 per ton.—The Hollinger return for the four weeks ended December 2 showed a large advance over any previous output, the gross profit was $210,559, from 29,448 tons, averaging $10.99 per ton. Working costs were $3.34 per ton. The mill also treated 11,214 tons of ore from the Acme. The surplus on hand is $1,525,130.—— The West Dome Consolidated, which has taken over the West Dome, will shortly begin development. Instead of deepening the old shaft, which is down 120 ft., a new shaft will be sunk

nearer the Dome, with a view to cutting an extension of some of its side veins.——The claims of the Porcupine Mines Syndicate, adjoining the Foley-O'Brien, are being developed by trenching and stripping the principal vein, which is thought to be an extension of the Foley-O'Brien vein. R. Hamilton, who was formerly engaged in mining in Chihuahua, Mexico, is in charge.—Diamond-drilling is being started on the Dome Consolidated, a property of 120 acres situated north-east of the Dome.

At the Croesus, formerly the Leyson-Dobie in Munro township, the main dome has been cut at 200 ft., where the high gold content of the ore on the upper levels is well maintained.

At the Tough-Oakes mine, Kirkland Lake, a telluride not previously known to occur in Canada, kalgoorlite has been found on the 400-ft. level. It contains more silver than gold, with some mercury. With it is associated calaverite more abundant and noticeable than the kalgoorlite.——The Lake Shore, in the Goodfish Lake area of the Kirkland Lake district, which has been extracting good ore at the 200-ft. level, has sunk to the 300-ft. level, where a station has been cut.

During assessment work at the Quinn claims, in Munro township, one mile east of the Croesus mine, owned by George Quinn, Archibald Burton, and P. S. Haviston, platinum was discovered in commercial quantities. About three months ago the men employed discovered a mineral which was not recognized by them, and the importance of it was not realized until recently, when one of the owners had some samples assayed. The ore, of which the principal constituent was iron, was found to be rich in platinum. Five assays were made of ore taken at different places, the platinum content being stated to run between $180 and $1800 per ton. Traces of platinum have previously been found in the locality, but this is the first occasion in which it has been discovered in paying quantities. The country, which has been all staked out as gold locations, will be closely prospected in the hope of finding further platinum deposits.

WASHINGTON, D. C.

Further Notes on the Mining Law Revision Bill.—Leasing.

The Senate has passed the bill of Senator Smoot of Utah creating a commission to codify the mining laws of the United States, and the bill has gone to the House of Representatives. There was no opposition whatever to the bill in the Senate, where it was passed in less than five minutes when called up by Senator Walsh of Montana, chairman of the Senate's committee on mines.

This was quick action, as was promised. The bill calls for the appointment of a commission of three members, two of them shall be lawyers of large experience in mining law, and a mining engineer who has had practical experience in mine operations. Alaska is included in the scope of the commission's work. Hearings are authorized to be held in the principal mining centres, and the work must be done in a year after the appointment of the commission by the President. $500 per month is allowed to each member of the commission, and $25,000 for other expenses.

Great opposition has arisen to the bill in the House, as previously indicated. The House committee on mining is still giving hearings, and among others lately heard have been J. Parke Channing, Henry B. Winchell, and W. R. Ingalls, and Senator Smoot and Congressmen Howell of Utah and Evans of Montana. Delegate Wickersham of Alaska has been heard, and he offered much opposition to any revision of the mining laws of Alaska, indeed of the whole branch of mining law. He was personal as well as caustic in his remarks.

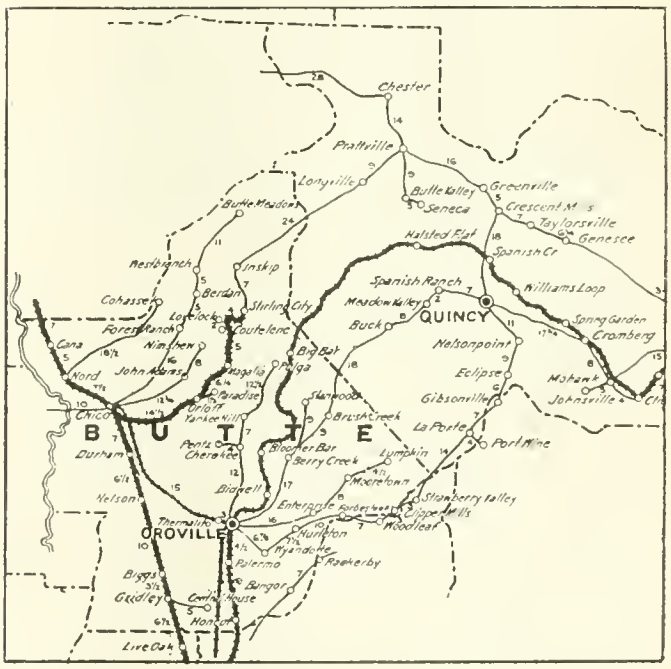
In the House committee on mining it is now said that leanings are against the recommendation and passage of any codification commission at all, and that a plan is gaining favor whereby the revision will be done in Congress by members of Congress, and that even the House committee on mines and mining may begin this work at once and send it up to the Senate when completed for action. The growth of this sentiment is quite unexpected and has been combated, the claim in answer being that the work of codification cannot be done adequately except by experts with plenty of time at their disposal and who shall be able to go about the country and come into touch with the views of practical mining men, who will be accessible only near their places of operation and who cannot come to Washington in any large numbers.

The leasing bills, so called, still occupy Congress. The House has passed the bill permitting the leasing of water-power sites on Government land still owned. A vigorous report has been filed on behalf of the minority on the committee on public lands, written by Congressman Taylor of Colorado.

MAGALIA, CALIFORNIA

Notes on an Old Drift-Mining District.

Drift-mining operations in this district have been more active than usual this winter, as a number of new operators have taken the field. The drift mines in Butte county have proved to be rich in the past, and should respond to further development. The question arises, why have these mines been dormant during the past few years? There are several answers; the



BUTTE COUNTY, CALIFORNIA, SHOWING POSITION OF MAGALIA.

two most important are adverse mining legislation, and the taking of nearly all available water by power companies. Water is very important in this class of mining, but the days are gone when the miner may take what water he wants to wash the gravel. Under favorable conditions drift mining may flourish. It is now a question of storing all the water and washing intermittently, except in some cases where the main workings of the mine may be near plenty of it.

The Oro Fino has come again to the production stage lately, under the experienced management of W. F. Anderson. Eight men are working. The property is near DeSabla.

George C. Allen and associates are opening the old Williams claim near Appleton. Three men are working, and an incline is being sunk on the contact to reach the gravel.

Henderson brothers have driven their adit into gravel near Magalia, and have four men working.

J. F. Littlefield has six men driving an adit from Little

Butte creek to a tributary channel of the Mammoth. An incline was driven for some distance, but had to be abandoned on account of swelling ground, an uncommon occurrence in this district. This property is well equipped, and may yet be heard of as a producer.

The Lucky John mine, nearby, is being opened by P. J. Dunne and others. This is a promising property, as a considerable amount of gold has been extracted from adjoining claims. The Mineral Slide, now idle, has produced over $1,000,000 since it was first opened. It still has possibilities, but will take a considerable sum of money to put in shape for resumption of work. It is not likely to remain idle long.

The Kirby mine, near DeSabla, is to resume shortly, as soon as a settlement has been made with Mushrush & Co. This mine is opened by a shaft to the gravel and is near the famous Indian Springs mine which has produced over $2,000,000.

J. Allen Veatch is employing 8 to 10 men on the Royal Drift and Robinson Drift mines on Big Butte ridge. This is a strong company, and development on a good scale is planned.

It is likely that other drift mines will be re-opened in the spring. It is time that these deposits received more attention, especially when one considers that since the early days they have yielded approximately $300,000,000, or an average of $1,000,000 per mile of channel worked. According to maps of the Geological Survey, there is an enormous length of ancient river-channels remaining in this State.

DEADWOOD, SOUTH DAKOTA

Wolfram Production.—Prospects of the Ofer.—Sundry Notes.

With a production of $147,000 of hand-sorted wolframite ore shipped to market in the past six months, and the accumulation of a low-grade dump estimated to contain $100,000, net, the Wasp No. 2 company, in the Flatiron district, occupies an enviable position both as a producer of first magnitude of this class of ore, and as a profitable concern as well. The last car of the ore, shipped in December, consisted of 26.25 tons of 40% product, sold to the Crucible Steel Co. for $47.50 per unit, the carload realizing $54,000. Production of this high-grade ore continues, meanwhile the new plant is at work concentrating the low-grade dump. The concentrating equipment, installed at a cost of $5000, includes a Davis roll, 5 by 4-ft. ball-mill, Richards jig, horizontal jig, classifier, elevator, Wilfley table, etc. It has a capacity of about 25 tons daily, and is expected to make a product containing 60% tungstic acid. During 1915 the company paid dividends of 16½c. per share, making the total distribution $82,500, and from present indications 1916 should be even more profitable.

With a production of over 50 tons daily, and the certainty that this quantity will be considerably increased within the next few weeks, the Ofer Gold Mining Co. has taken an enviable position among Black Hills producers. It is the old story of a mine supposedly worked out, showing, under development in adjoining ground, orebodies not known to exist. Most of the output, from 40 to 50 tons per day, is being extracted by the Mogul company, which has the Ofer's Burlington and Apex group under lease. This ore is of good milling grade, and there is a considerable quantity of it. It is a continuation of a shoot which the Mogul discovered in the North Lode—its own property—and from which a large tonnage was taken last year. The Mogul worked this shoot up to its boundary lines on both the north-west and south-east of the North Lode. On the south-east the shoot extends into the Burlington and Apex group, and on the opposite side, into the Monday-Reindeer group, both belonging to the Ofer company. And, as has been stated, the Mogul secured a lease on the Burlington and Apex, and is negotiating for an agreement whereby the ores of the Monday-Reindeer group may also be secured. While terms have not been definitely agreed upon, it is practically assured that the Mogul will treat the latter ores, either by lease or working agreement. This will bring the Ofer's output up to probably 100 tons daily from this one ore-shoot, and should it prove as extensive and valuable in Ofer territory as it was in Mogul ground, will net the company a splendid profit. Schilplin and Moore have been granted a lease on the Ofer's Lackawanna fraction, and production will immediately commence from that ground, as ore is known to exist in paying quantities. On the American Express group, also Ofer territory, on Blacktail and Sheeptail gulches, lessees Phillips and Caretto are taking a narrow-gauge carload—15 tons—daily from the old dumps. This ore is being treated at the New Reliance mill, and good profits earned. Underground conditions are favorable at this property for a large future production, as there appears to be a large quantity of $5 to $8 ore developed, ore which would not pay to work at the time the property was operated, some 15 years ago. Plans are also maturing for unwatering the Imperial shaft, in Blacktail gulch, where considerable $6 ore was found some years ago—likewise at a time when that grade would not pay to work. The Ofer company has plans for a comprehensive development of its estate, and the present production and earnings indicate that it will have sufficient funds to proceed along broad lines of development and firmly establish another big mining enterprise in the Bald Mountain district.

Sinking is again under way at the Hidden Treasure shaft, in Deadwood gulch. The work will be carried to the 400-ft. level, 200 ft. below the present bottom.——Operations are being conducted steadily at the Rattlesnake Jack mine, near Galena, where, since the installation of Wilfley tables, a better saving is being made. Concentrates assaying $160 to $200 per ton are being saved. Cyanidation is also yielding good returns.——A 10 by 12-ft. Portland filter is being installed in the Megul mill at Terry, supplementing the continuous-decantation process. The machine will be particularly valuable in the saving of cyanide, although some dissolved gold will probably be recovered that now goes to the dump.——Lateral work continues on the 600-ft. level of the North Homestake, and the 200-ft. level of the Echo, both at Maitland.

AUSTIN, TEXAS

Sulphur, Iron Ore, Zinc Imports, Quicksilver.

The Freeport Sulphur Co. of Freeport, is preparing to build a loading-dock on the west side of the Brazos river near its sulphur mines. The dock will be 300 ft. long, and equipped with modern loading machinery. The company is arranging to increase its sulphur output considerably. A new boiler-plant is being erected to increase the output from 10,000 to about 22,000 hp. It is estimated that this additional power will enable doubling the sulphur output of the wells.

A. G. Elliott, Jr., and associates of Dallas are perfecting plans for the extensive development of their iron-ore deposits in east Texas. They control beds in Cass and Marion counties that are estimated to contain a minimum of 100,000,000 tons.

The Bailey Mining Co. has been organized with offices at Burnet and Lometa. It has a capital of $40,000.

The British steamer, *Chalister*, arrived at Galveston on December 18 from Australia with a cargo of 7500 tons of zinc concentrate for the smelters at Bartlesville, Oklahoma. It is the fifth vessel to bring this product during the past six months. It is stated that two other steamers, the *Toromeo* and the *Conargo*, are now on the way to Galveston with similar material.

It is interesting to note that the Terlingua quicksilver district continues to expand. Two old mines are to be unwatered. The territory adjacent to Terlingua across the Rio Grande in Mexico is again attracting attention.

The tungsten mine of T. Owens and E. Kiam, 30 miles north of Van Horn, promises to be extensive.

Machinery has been installed at the molybdenum mine of E. Kiam and W. J. Badu near Llano.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

The Alaska Gold Mines Co. is to issue monthly statements; that for December is now available. The mill treated 114,183 tons of $1.36 ore.

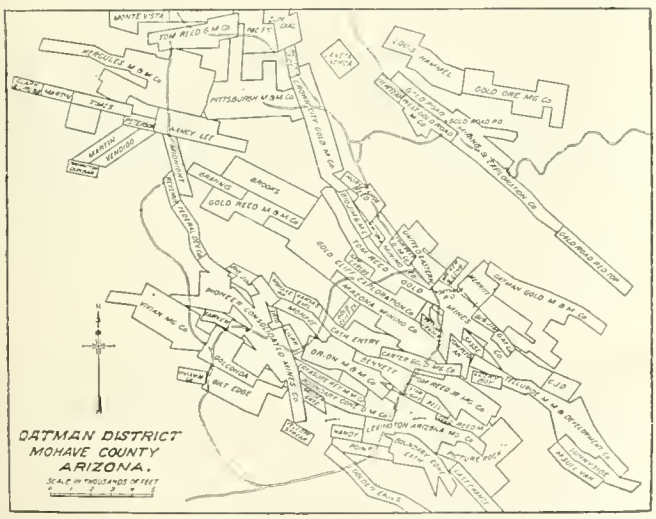
Two men were killed above the 1450-ft. level of the Alaska Treadwell mine on January 4. They were bulldozing large boulders. A quantity of giant powder exploded near-by.

ARIZONA

Bulletin No. 10 of the State Bureau of Mines is entitled 'Gold Placers of Arizona,' by Frank G. McClure. A table gives the gold output from these deposits from 1903 to 1912, inclusive. Yavapai county has one of the large areas, in the south-central part, 60 miles north of Phoenix, along the Hassayampa river. One problem is that of water supply. Pima county has three important districts, while those in Yuma are of value.

MOHAVE COUNTY

It is considered probable at Oatman that the Tom Reed-United Eastern merger will not be consummated. Negotia-



tions continue. Erection of machinery at the latter is making good headway.

Tonopah and Goldfield people have acquired an interest in the Times property, about four miles from Oatman, where some good ore was opened recently. Charles E. Knox and Ben S. Revett are mentioned as new shareholders.

About 100 men are working at the Tennessee mine, 28 miles north of Kingman. The daily output of zinc-lead ore is 150 tons, concentrated at Needles, and the product smelted at Bartlesville, Oklahoma, and Midvale, Utah. A wide vein is being developed at 400, 800, and 1170 ft. The main shaft is being sunk from 1200 to 1400 ft. Work at the Schuykill, Payroll, and Minnesota, near the Tennessee, is giving encouraging results.

The Pittsburg mine has been sold to Eastern people for $300,000. This is one of the most important transactions in the Oatman district.

A fine body of tungsten ore has been opened at 40 ft. depth in the property of J. C. Wichmann, 12 miles east of Yucca. A mill is soon to be in operation.

The Arizona Venture Corporation shipped last week, through its agent at Kingman, W. D. Grannis, 256 crystals of leuzenite. These are used in wireless telegraphy.

YAVAPAI COUNTY

It is reported that at 1400 ft. in the United Verde Extension at Jerome the cross-cut has passed through two 6-ft. veins of 20% ore, and one 8-ft. of 23% copper. The new machinery and tramway from the mine to the United Verde smelter at Clarkdale are ready for work.

ARKANSAS

According to Reuben Willett of Yellville, who buys most of the zinc ore from the North Arkansas field, and supplies the U. S. Geological Survey with production figures, he estimates that the output in 1915 was 15,429,010 lb., worth $1,000,000, an increase of 400%. This yield was from 87 mines. Carbonate and silicate ores amounted to 14,064,315 lb., of which 6,841,325 lb. was shipped without milling. Many mills are in course of erection. The output in 1916 should be 30,000,000 lb. The counties are Boone, Baxter, Marion, Newton, and Searcy.

Grading has been started on the new railroad between Yellville and Rush. The line will be ready in July, and should be of great benefit to the mining industry of north Arkansas.

CALIFORNIA

Considerable snow has fallen in all the mountain counties, which, while it will be of great value later on in the year, has considerably interfered with mining operations.

AMADOR COUNTY

The following is the preliminary report of the Plymouth Consolidated for December:

Ore milled, tons	11,650
Value of gold	$58,490
Working expense	26,324
Development charge	5,215
Surplus	26,951
Other capital expended	206

During the six months ended December 31, 1915, the Keystone company at Amador City produced $86,167 from 38,663 tons of ore, equal to $2.23 per ton. The 40-stamp mill only lost about 5½ days during the period. Most of the ore came from a depth of 900, 1000, and 1200 ft. Work at 1400 ft. is highly encouraging. The balance on hand is $6465. Carlton R. Downs is manager.

A mill may be erected at the Treasure mine in the spring. The property is between the Bunker Hill and Fremont mines.

CALAVERAS COUNTY

(Special Correspondence.)—The Pioneer Chief Gold Mining Co., with offices in San Francisco, and whose property is situated about two miles south of San Andreas, on the foot-wall' belt of the Mother Lode, has installed electrical equipment consisting of hoist and air-compressor of sufficient capacity to meet requirements for some time to come, and to operate to a depth of 1000 ft. A full two-compartment shaft is being sunk, and is down 320 ft., showing a five-foot shoot of high-grade milling ore. Sinking is under way on three shifts, using ma-

chute drifts, crosscuts will be cut at 50 and 100 ft. The 220-ft. level has been extended 175 ft. south, and 165 ft. north. The ore now being developed assays from $5 to $10 per ton, although some parts of the mine yield up to $7.0 and $50. The assay office is being erected, and preliminary plans are being drawn for a mill, the first unit to be 100-ton capacity. The company has built its own power line connecting the mine with the main transmission line, receiving electricity from the Electra power plant of the Pacific Gas & Electric Co. J. F. King is local superintendent.

San Francisco, January 17.

Inyo County

(Special Correspondence.)—A heavy snowstorm at the beginning of the year caused a break in the pipe line, leaving Skidoo to subsist on melted snow for five days.

Many prospecting outfits have passed through here lately. Stibnite and possible scheelite deposits along the western side of Death valley are the attraction.

Skidoo, January 9.

Nevada County

A 475-gal. per minute pump, driven by a 10-hp. motor, has been added to those already lifting 1100 gal. at the Golden Center mine. Water from Wolfe creek seeps into the workings.

At the eighth annual meeting of the Le Due Mining Co. it was decided to continue development in charge of B. A. Penhall. Over 3400 ft. of adits has been driven, but no commercial orebody has been developed.

The recent storms considerably upset work around Grass Valley, mainly through a shortage of water.

Placer County

Owing to a legal tangle over title to three areas of ground at Forest Hill, the Grey Eagle company has suspended operations, probably for several months.

Plumas County

Developments in the Walker copper mine continue very satisfactory, a wide body of good ore being recently opened. Diamond-drilling is to be started soon.

Nevada and California people constituting the Lucky Strike company, headed by H. O. Howard of Lovelock, have acquired the King Solomon claims. Men will start work in March.

Shasta County

To obviate litigation concerning the Peterson-Lutman property on Clear creek, the partly completed dredge of Lawrence Gardella was moved 200 yards in 40 minutes by 11 men on January 14. A temporary canal was cut for the boat.

Ground left by the Shasta Dredging Co. at Horsetown is being sluiced by J. G. Andree and C. O. Silversten. Dynamite is used to loosen the gravel. Two clean-ups were satisfactory.

Sierra County

At the North Fork mine, at Forest, the shaft is being sunk to 200 ft. depth. Some rich arsenical pyrite was extracted at 185 ft. G. L. Stone is in charge.

At Allegheny the Kendricks Consolidated is to operate some claims in charge of C. O. Jackson.

Tuolumne County

The Buchanan gravel channel has been cut by the 200-ft. adit driven by the Springfield Tunnel & Development company.

COLORADO

Clear Creek County

(Special Correspondence).—The Argo mill, which has the largest cyanide-plant in this county, is being provided with flotation equipment. It will consist of six cells, making it possible to treat 200 tons of ore daily. Only tailings from the mills will be treated, but it is hoped to increase the recovery considerably, no effort having been previously made to extract the silver and lead contents of the ores. J. A. Pearce is in charge of the mill.

The Onelda mill at Freeland is being operated full time, treating an average of 50 tons daily. This plant has a flotation plant. It is officially announced that the cost of oil is 3c. per ton.

Work will be started in a few days on the Lord Byron property, near Lower Fall river. The Stanley adit will be extended 500 ft. to intersect the Lord Byron vein at increased depth. D. J. McDonald is manager.

The discovery recently made in the Albro mine on Albro mountain is developing into a bonanza. The vein is two feet wide, and from a shipment of 30 tons made last week the lessees, Dingle, Swanson, and Shaffer, received a check for $2200. It is stated that the output will be at the rate of one carload per week.

Mosher and associates, leasing at the East Lake, have opened another orebody that is three feet wide, and the initial shipment returned a settlement of 3.25 oz. gold per ton.

The Argo O. R. & P. Co. purchased in 1915 a total of $125,000 in gold and $19,000 in silver, while the Chamberlain Ore Co. paid out $350,000. Shipments made to the Salida smelter brought the production for the Idaho Springs district to $718,000.

Idaho Springs, January 9.

Lake County (Leadville)

The pumps at the Penrose shaft are now below 710 ft., lifting the water with ease. There is about 135 ft. more to unwater. Some old workings are being cleaned out.

Extensive development is promised for the Iowa Gulch area; some of which is to be examined in the spring. Lessees in the upper workings of the Lilian are shipping gold-bearing oxide and carbonate of zinc.

Summit County

Two of the Tonopah Placers Co.'s dredges were stopped for the season on December 31; the third will continue through the winter as usual. The French company's boat is closed also.

Both the mills of the Wellington Mines Co. are working full time.

Lessees at the Dunkin, near Breckenridge, recently sent another lot of ore direct to the Mint at Denver. This was worth $12,000, making $40,000 from the pocket.

Teller County (Cripple Creek)

Extraordinary rich ore is reported as having been found in the Vindicator, even better than that extracted from the Cresson. About 70 tons of 25-oz. ore was shipped from the Cresson mine last week to the Golden Cycle mill at Colorado City.

Lessees at the United Gold Mines Co.'s Bull Hill claims produced 800 tons of ore in December.

IDAHO

Shoshone County (Coeur d'Alene)

The Highland-Surprise Consolidated company, operating in the Pine Creek district, has overhauled and added to its plant, and since November 16 has treated 2500 tons of ore, producing concentrates assaying 55% zinc and 38% lead. More machinery will give 80% and 85% recovery of the zinc and lead respectively. Ore worth $105,000 has been shipped from No. 1 stope in the Surprise mine. No. 2 stope produces the present mill feed, and it is different from the other, requiring finer grinding and flotation. Development generally is very satisfactory. Bad roads, nine miles to the railway, hinder work, and a railroad is wanted.

On January 23 the Success company will pay 3c. per share, equal to $45,000. Net earnings in December were $90,000.

On the 100-ft. level of the East Caledonia 30 in. of 15% lead ore has been opened. The main workings begin on the level of the principal street of Wardner.

MICHIGAN

The Copper Country

(Special Correspondence.)—The Calumet & Hecla smelter at Hubbell is producing 440,000 lb. of copper daily. The metal goes East by rail. Work on furnace No. 23 is making good progress. The plant at Dollar Bay treats most of the 'mineral' from the company's subsidiaries.

Mass copper of considerable quantity is being opened in the north section of the Ahmeek mine.

The increased assessed valuation of the Copper Range Consolidated properties for taxation is the subject of protest from the owners, the manager of the Baltic, F. W. Denton, paying taxes in Adams township under protest.

Discussion has arisen over the greater speculation in copper stocks in New York than in Boston. Several Lake Superior companies are to be listed on the New York exchange. Boston capital is entirely responsible for the development of the Michigan copper deposits.

Houghton, January 10.

According to James MacNaughton, general manager of the Calumet & Hecla, the past year was one of notable achievements for the Michigan copper mines. The properties were never so efficiently operated. Ore has been mined and milled for $1 per ton in several instances. The C. & H. re-grinding plant is treating from 1200 to 1400 tons of tailing daily. The leaching plant will not be ready for six months. The outlook for the region this year is most encouraging.

MISSOURI

Jasper County

Cold weather last week considerably affected mining operations in the Joplin district. The street-car service was interrupted, preventing miners from getting to work. Water-pipes burst in many places.

The production of ore last year was as follows in tons:

State.	Blende.	Calamine.	Lead.	Value.
Kansas	28,089	.....	1,649	$2,105,912
Missouri	232,097	21,411	33,993	21,307,176
Oklahoma	27,955	84	9,675	2,625,556

The output in 1914 totaled $11,922,837.

MONTANA

Fergus County

A dividend of 7½c. per share, the first, has been declared by the Barnes-King Development Co. A monthly output of $100,000 is expected before the end of 1916.

Granite County

A revival is reported from the Henderson district near Philipsburg. The Henderson company has 40 men at work, and is shipping copper ore. The Coyote mine is a gold producer, with a 10-stamp mill. Other properties are considered promising.

Lewis and Clark County

The Anaconda company's bond on the Porphyry Dyke mine, west of Rimini, has been extended for further development and mill tests.

Silverbow County

Work is to be resumed at the Butte & Zenith mine, according to word from Duluth, where the directors recently met. John D. Pope is to be consulting engineer, with W. D. Gibson as mine foreman. The Montana Power Co. is to supply electricity. A good flow of water must be pumped. The property is four miles west of Butte.

In the suit of Peter Geddes and others, minority shareholders in the Alice Gold & Silver Mining Co. *v.* the Anaconda Copper Co., an appeal has been taken to the Circuit Court of Appeals at San Francisco, to try and set aside the order for re-sale of the property, held at Butte on November 10, 1915. The Anaconda company, which bought the Alice, a zinc mine, for over $1,000,000, has a large number of men at work.

The east Coeur d'Alene region of this State, an area of 20 sq. miles, extending three miles into the eastern part of Idaho, has attracted considerable notice during the past year. Saltese is the centre. Two main railroads run through the area. There are two large mineralized zones, probably an extension of the lead and copper belts of the Idaho Coeur d'Alene. Some

THE COEUR D'ALENE REGION OF IDAHO AND MONTANA.

of the most promising mines are the Hemlock, Last Chance, Tarbox, United States, Bryan, Silver Cable, Richmond, St. Lawrence, and Monitor.

The Montana Silver-Lead Mining Co. has developed a large quantity of ore on Leigh creek, near Libby, and will erect a mill next summer. Joseph Williams is manager.

NEVADA

According to Frank M. Manson, general manager of the Utah Ore Sampling Co., Nevada is at present employing more miners and shipping more ore than at any time in the past few years, there are more prospective shippers being developed, and a more optimistic feeling prevails relative to the mining industry than in years.

According to a bulletin of the Mackay School of Mines at Reno, antimony in the form of stibnite, the sulphide, occurs widely distributed in Nevada. Stibnite is the principal ore of antimony, containing when pure 71.4% of the metal. It is a soft, lead-grey, metallic mineral having a high lustre, and usually occurring in aggregates of bladed crystals and in radiating groups, while more rarely it is found in massive or granular form. Near the surface, the Nevada antimony deposits contain cervantite, an oxide of antimony, which has been derived from stibnite by oxidation, and appears as a pale yellow earthy mineral. Other minerals containing antimony which occur in Nevada are pyrargyrite, poly-basite, and stephanite, which are of more value for their silver than for their antimony; jamesonite and its derivative bindheimite, which are not valuable as antimony ores because of their lead content; famatinite, a variety of which occurs in the rich gold ores of Goldfield, and is called goldfieldite, and tetrahedrite, also a copper-antimony sulphide frequently of value for its gold and silver output. None of these minerals are of value as ores of antimony.

The known occurrences of stibnite in Nevada are as fol-

lows: Churchhill county, Barnes and Hoyer districts, Elko county, Columbia and Good Hope, Eureka county, Stafford, Humboldt county, Antelope Springs, Bloody Canyon, Jackson Canyon, Juniper Mountain, Lovelock, Red Butte, Rosebud, Seven Troughs, Star Canyon, and Winnemucca, Lander county, Battle Mountain and Big Creek Canyon, Mineral county, Aurora, Nye county, Hot Creek district.

At Columbia, in Elko county, and in the Stafford district of Eureka county, the stibnite was mined for its silver content, while at the other localities named, it has been exploited for antimony. Before the outbreak of the War, all of the Nevada antimony deposits were shut down on account of the low price of the metal, which was only 8½c. per pound. Since then the price has risen to 37c., and a number of the properties are now working. Among these may be mentioned Antelope Springs, in Humboldt county, where the ore is said to be chiefly a high-grade oxide, but as yet a depth of only 30 or 40 ft. has been reached. In the Red Butte district, mining operations were begun last summer, and as in the preceding case, the ore was mainly high-grade oxide. Here, however, stibnite began to appear at a depth of a few feet. The Sutherland mine near Lovelock was worked last summer by the Magnolia Metals Co. of New York, which also operated the prospect near Red Butte. The deposits at Bernice are said to be working now, and there are doubtless a number of deposits in the State which are working at the present time. Anyone interested in an antimony deposit should attempt to get out as much ore as possible in as short time as possible, because it is practically certain that as soon as the War is over, the price of antimony will again drop back to the normal level of 8½c. It is probable that many of the deposits mentioned in the above list, and not in operation at the present time, could be made to produce antimony at a profit with the present price of the metal, and it is to be hoped that their owners will take advantage of the opportunity.

Esmeralda County

During December the Jumbo Extension produced 2938 tons of ore worth $110,000. Sampling, freight, and treatment cost $28,000; smelter losses, $12,500; and working costs, $16,500, leaving $53,000 net. The total output in 1915 was 22,508 tons for $921,780, yielding $403,827 net, of which $333,750 was paid in dividends.

In the January issue of *Leschen's Hercules*, A. Leschen & Sons Rope Co. of St. Louis, describes the electrically operated Lidgerwood cable-way of 1790-ft. span for carrying old tailing from dumps to the Goldfield Consolidated mill. The capacity in 16 hours is 1000 tons.

The Reorganized Kewanas Mining Co.'s annual report has been issued; including the remarks of the general manager A. I. D'Arcy. The area of the two claims is 34 acres, adjoining the Laguna mine of the Goldfield Consolidated. The shaft and equipment of the Laguna are used for development of the Kewanas property at 700 ft. depth. Some encouraging results were obtained, although enough high-grade ore was not found to warrant shipments. There is a lot of unexplored territory in the property yet, and treatment of the gold-copper ore is soon to be possible.

The Reorganized Booth Mining Co. has also issued its annual report, including one from A. I. D'Arcy. The cash balance at December 1 was $197,458. The company realized the sum of $187,316 from the sale of 135,400 Jumbo Extension shares, and received $19,275 in dividends on stock owned during the year. Development amounted to 2239 ft. The report discusses the extra-lateral aspect of the Booth vein and the Jumbo Extension property, which dispute was settled by the Jumbo Extension company giving $15,000 cash and 300,000 shares, in return for that portion of the Booth vein lying within vertical planes drawn through the exterior boundaries of the Jumbo Extension. The vein was thoroughly prospected during the suit, but no commercial ore was found. The mine was closed until August, 1915, to await further developments in the district. An apex dispute with the Goldfield Consolidated, Reorganized Kewanas, and Merger companies was also settled, on a share basis.

Humboldt County

At 1500 ft. in the Seven Troughs Coalition S in. of $1200 ore is being driven on. The mine is a veritable bonanza.

Recent developments at the Colligan lease of the Weaver No. 2 claim, prove the extension of the ore-zone of Rochester hill by several hundred feet.

Nye County

The Kansas City-Nevada Consolidated Mines Co., operating at Bruner, has issued a circular to the shareholders of the Phonolite Paymaster Mining Co., and the Phonolite Silent Friend Mining Co., whose properties, with others, were recently examined by C. M. Heron. A consolidation of all the claims was agreed upon, the above company being organized with a capital of 6,000,000 $1 shares, which have been distributed as necessary. The president is E. C. Sooy of Kansas City, vice-president of the Lucky Tiger company, operating at El Tigre, Sonora, Mexico. H. W. Bruner is general manager.

Tonopah companies and lessees last week produced 8597 tons of ore worth $180,006. All the properties continue their usual operations, on which there is nothing of special importance to chronicle. The Belmont company has examined the Bull Moose claims near Realty. Judge Averill made a decision in the Extension-West End suit, defining where the latter may work, and fining it $10 and costs for inadvertant contempt.

UTAH

Beaver County

(Special Correspondence.)—According to William Farish, who has examined the Newton district surrounding Fortuna, a general connected gold belt extends from a point west of Fortuna east past the Sheep Rock mine on to the Annie Laurie mine at Kimberly, a distance of at least 10 miles by air line. If such is the case, the gold-bearing area extends fully 10 miles east and west and 10 miles north and south, so far as is known. The general formation is made up of different kinds of porphyry. The veins are numerous, running north and south. They vary greatly in size. This series of veins is cut by east and west veins, which occur at frequent intervals, say 100 to 1000 ft. apart. In many instances there is a slight faulting of the north and south veins at the intersection. The east and west veins are generally smaller than the others. Several north and south veins are fault fissures. These in many instances fault the east and west veins from 100 to 200 ft. Both series of veins are gold bearing. There are said to be many veins from 100 to over 200 ft. in width that carry from $3 to $6 per ton their entire width. Generally Mr. Farish considers the district of much promise, and worth the attention of capital.

Fortuna, January 10.

Juab County

Attention is being directed to the large mineralized area west of the Tintic district. Several properties are developing favorably.

Property owned by the Chief Consolidated company at the east and north ends of the district is to be developed as soon as possible.

On January 25 the Iron Blossom company will distribute 5c. per share, equal to $50,000. The property is in splendid condition.

Summit County

On January 16 W. R. Elliott became manager of the Three Kings company, with Joseph Kemp as superintendent. The main shaft is down 500 ft., where a drift has been driven 450 ft., lately in favorable ground.

To overcome the shortage of water the Daly West company

has ordered pumps to be installed at 1200 ft. in the mine. The water will supply the mill.

WASHINGTON

A review of mining conditions in Washiugton, Idaho, Oregon, and Montana during 1915 has been issued by F. A. Thomson, head of the mining department of the Washingtou State college at Pullman. Discussing the Tacoma smelter he says that the old lead and copper plant has been virtually re-constructed, and is rapidly becoming one of the most complete copper plants in the country. The lead furnaces were taken out several years ago, and this year has seen the completion of the most modern electrolytic copper refinery in the West, having a capacity of 6000 tons of copper a month, which with the old refinery gives a total of 8000 tons. A 130-ft. oil-fired reverberatory is under construction. This is to take care of the Britannia concentrate. A Cottrell fume plant is to be built early in the year. Alaska, British Columbia, and South America are the main sources from which the Tacoma smelter draws its ore supply.

CANADA

British Columbia

A new contract has been secured by the Lucky Jim company at Zincton for its zinc ore and concentrate; for 1000 tons the net return will be $3 per ton more than the previous arrangement. The mine is looking well.

A barge on Slocan lake, carrying concentrate worth $12,000, the property of the Standard Silver-Lead company, lost this product during a storm two weeks ago.

Zinc ore and concentrate from Kootenai mines last year totaled 13,058 tons, an increase of 2869 tons over 1914. All was sent to United States smelters. Twelve mines contributed.

On February 29 the Hedley Gold Mining Co. will pay 3c., and an extra of 7c., making a total of $120,000.

Ontario

(Special Correspondence.)—The current year opens full of promise and increasing activity, 35 properties showing signs of renewed work. When construction at the Hollinger and Dome are complete the gold output will be greatly augmented. ——The surface plant at the Success has been thoroughly overhauled, and the new owners are ready for extensive development.——The Apex plaut is also being prepared for resumption of development.——Many rumors are heard regarding renewed work at the Moneta.——The Staudard has been optioned to Boston interests, who are to commence at an early date.——In the north cross-cut at the 100-ft. level 40 ft. from the shaft, the Hayden company cut the orebody that dipped out of the shaft at a depth of about 60 ft. The cross-cut is through 21 ft. of ore worth from $12 to $48 per ton, with the face still in ore.

The Jamieson claims in Robb township have been optioned to people represented by Duncan Chisholm of Toronto, for a price said to be $175,000. A small payment has been made and work has been commenced.———The owners of the McLean claims in Turnbull, are soon to commence some further development of their holdings.——It is rumored that the McAulay-Bridge claims in Bristol township have been optioned to Toronto financiers.

Permission has been granted by the Ontario government to some of the owners of claims in the Tashota Lake district to go ahead with their assessment work. Permission had not been granted previously because it was thought that the Nipiyon Forest Reserve covered most of the district. Excellent discoveries have been made on several properties, notably the Devaney and Brenuan Kline groups; the Green claims all have yielded good results in panning and sampling.

Work is proceeding on the molybdenite property owned by Smith and House near mileage 77 on the T. & N. O. railway. Camps are being erected, and preparation being made for continuous shipment of ore.——Interestiug discoveries of tungsten ore have been made near North bay; the situation is a secret and is occasioning local excitement.

Porcupine, January 4.

During 1915 the Dome miue produced 317,873 tons of ore averaging $4.68 per ton. The first Hardinge mill is at work. Worn out stamp batteries will be replaced by these machines.

Work has been started at the La Belle Kirkland Lake Gold Mines property. The new plant cost $20,000. Sinking is under way. Prospects are considered good.

During December the Nipissing high and low-grade mills treated 71 and 6754 tons of ore respectively, yielding bullion worth $112,907. With this and custom products the refinery produced 681,213 oz. Underground work was favorable. Equipment is finished at shaft 81, which is 90 ft. deep, and is to be continued to 480 feet.

Some 3000-oz. ore is being extracted from the Chambers-Ferland.

KOREA

The Seoul Mining Co., operating the Suan concession, reports the following results for December:

Ore treated, tons	16,880
Mill operated, days	28
Bullion recovered	$ 72,250
Concentrate	50,420
Total	$122,670
Expenses	$ 65,000
Net	$ 57,670
Received by adjnstment of smelter returns on concentrate shipped during 1915, due chiefly to increased price of copper, an excess over estimated value of	$ 55,000
Total for month	$112,670

MEXICO

Large shipments of coke for the plants of the American Smelting & Refining Co at Monterrey, Chihnahua, Matehuala, and Velardena are going into Mexico from Birmingham, Ala. Three furnaces have been blown-in at Monterrey. The Matehuala smelter treats only copper ore, and that at Velardena is equipped to reduce copper as well as lead. Work at Chihuahua will be delayed by the recent murders. The smelter at Aguascalientes is also to be re-started.

El Oro

During the annual meetiug of the El Oro Mining & Railway Co., held at London late in December, the chairman, R. T. Bayliss, made the following remarks regarding operations in Mexico:

"Since we were compelled to close down in February last (1915), the main object has been to keep the mines free from water. Should we fail in this, considerable damage would be done to the lower workings, and much delay would occur when we were able to resume operations. The other work which was done since February has been done partly from motives of common humanity and partly from prudence. That is to say, the native population of the camp, when the works were closed down, was in danger of starvation; and we have been employing from 500 to 600 men to avoid this calamity. A starving Mexican population is a dangerous element; and it has only been by the co-operation of the mining companies in the El Oro district that a very serious situation has thus been avoided. Incidentally, this policy has enabled us to maintain the mine workings in good order and to do a small amount of development. The interruption which has thus occurred in our operations is exasperating to a degree, for I do not think the prospects of the El Oro company were ever brighter than they were 18 months ago. The development of the Ofir claim,

which was purchased in November 1912 had, up to the time that work was stopped, exceeded all expectations, and was placing us in possession of a large reserve of ore which, for the El Oro district, was of high grade. The development of the various veins in the Sonora claim was also fully justifying all forecasts, and the directors were looking forward to a period of prosperity, equalling anything the El Oro company had experienced in the past. So long as no physical damage is done to the property—and I am pleased to be able to say that so far no extensive or material injury has been done—we shall be able to take up this work on resumption where it was left off. When we do resume, we shall be confronted by many difficulties. There will probably be a considerable increase in taxation on output, and a higher cost for labor, supplies, and so forth, and the general cost of operations will be increased by this sum, whatever it may be. On the other hand, it is confidently expected that when tranquil conditions are once more established, several advantages will tend to offset these increases.

Just when we shall be able to resume it is, at present, quite impossible to predict. While for the time being there is a lull in the military activities among the various factions in the Republic, those best able to advise the directors cannot foresee any immediate prospects of a recovery in the political and economic conditions of the country which would warrant us in re-commencing operations at an early date. It is, moreover, the determination of the directors that they will not, if they can help it, jeopardise the interests of the company by attempting to re-start operations unless, and until, we have a reasonable assurance that we can continue the work unmolested for an indefinite period. It is a matter of great regret that we cannot tell that shareholders' troubles are at an end. They are not, and I should be misleading you if I pretended they were."

Jalisco

The Cinco Minas Co. has operated about 60% of the time during the last two years. It started operation again at full capacity on November 30, 1915, and at present remains at that pace. The company experienced no great difficulty through revolutionary trouble, except that transportation for the past six months has been greatly demoralized. At present there is six months' supplies on hand, and steady work is contemplated. Bullion and concentrate has been shipped from the property *via* Manzanillo and San Francisco. The mill is treating 340 metric tons per day in a plant designed for 250 short tons. A contemplated increase to 500 metric tons will be made in the near future, and a few additions will give this capacity. The plant has been giving about 93% extraction. It was designed by the late Godfrey Doveton.

Sonora

Cananea is suffering from a shortage of Mexican labor. Nacozari is busier than usual.

Schools and Societies

The Bulletin of the Massachusetts Institute of Technology for December consists of 597 pages. It includes a catalogue of officers and students, with requirements for admission, and notes on the courses of instruction. The laboratories are described, and prizes offered are discussed. The second term of the school-year 1915-1916 begins on February 7.

The U. S. Civil Service Commission announces an open competitive examination for physical metallurgists on February 2, 1916. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Navy Yard, Boston, Massachusetts, at a salary ranging from $4 to $6 per diem, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

PERSONAL

O. E. Jager has arrived from Peru.

W. Spencer Hutchinson, of Boston, is here.

A. P. Rogers is on his way to Oruro, Bolivia.

L. B. Spencer is here from Hawthorne, Nevada.

J. H. Francl of New York is at the Palace Hotel.

Hamlin Stivens is visiting New York from Mexico.

T. Skewes Saunders is in New York on his way from Mexico to London.

George Watkin Evans, of Seattle, is on his way to Washington, D. C.

Louis A. Wright has gone to Chile for the American Metal Co., of New York.

W. E. Upham, Michigan College of Mines, 1895, is in San Francisco, at 1451 Taylor street.

J. R. Finlay has been elected president of the Mining and Metallurgical Society of America.

R. M. Raymond is making a visit to Mexico, before commencing his lectures at Columbia.

Norman C. Stines sails from New York on February 1, returning to Russia by way of London.

W. A. Karri-Davies, so honorably known in South Africa, is at the Hotel Claremont, Berkeley.

Harold Whittingham, Michigan College of Mines, 1911, is a captain of British artillery in France.

N. O. Lawton is at Sneedville, Tennessee, where he will for several months conduct explorations in Hancock county.

Frank M. Leland has resigned as manager for the Empire Copper Co., at Mackay, Idaho, becoming consulting engineer to the same company.

John G. Kirchen, general manager of the Tonopah Extension Mining Co., has been elected president of the Nevada Mine Operators Association.

W. J. Loring has not left the firm of Bewick, Moreing & Co. His taking of an office in San Francisco simply marks his firm's interest in Pacific Coast mining.

F. G. Clapp, managing geologist of the Associated Geological Engineers, has returned from the Oklahoma fields, and may be addressed in Pittsburg for the next few days.

R. T. Bayliss, chairman of the El Oro Mining & Railway Co. of El Oro, Mexico, at the recent annual meeting, made the following statement: "Six of the younger men of the staff recently employed at El Oro joined the colors, and have been engaged in active service in France. One of these, Mr. Lacy, was awarded the Distinguished Service Order; and it is a pitiful reflection that the announcement of this award, and his promotion, should have been received upon the day on which he was killed in action. Two of the others, O. D. Filley and G. A. Syme, have received the Military Cross for conspicuous gallantry, and I think the fact that three out of the six men who volunteered from El Oro should have earned these distinctions gives an accurate impression of the character of the men whom you have in your employ."

William J. Wallace, formerly superintendent of the Cusi Mining Co. at Cusihuiriachie, was among those killed by Mexican bandits last week. Wallace was from Houghton, Michigan, a graduate of the Michigan College of Mines, 1905, and a member of Sigma Rho fraternity. He leaves a wife at Tombstone, Arizona.

THE METAL MARKET

METAL PRICES

San Francisco, January 20.

	Cents per pound.
Antimony	44
Electrolytic copper	25
Pig lead	6.15—7.10
Quicksilver (per flask)	$225
Spelter	21
Tin	43
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, January 20.

Antimony: lower, 50% product, per unit	$2
Chrome: 40% and over, f.o.b. cars California, per ton	15—18
Magnesite: crude, per ton, f.o.b.	7.50—10
Magnesite: plastic, no iron and lime, calcined, per ton	50
Magnesite: refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	40—50

For 26.25 tons of 40% product (wolframite) sold in December to the Crucible Steel Co., the Wasp No. 2 company of South Dakota realized $47.50 per unit.

The United States output of tungsten concentrate in 1915 was 2165 tons, worth $2,000,000.

New York, January 14.

Antimony: per unit	$2.20
Molybdenite: per lb.	1.40

Tungsten is exceedingly firm at $60 for spot, that price having been paid for several lots for immediate delivery. Contracts covering eight or nine months of this year have been made at over $40. Dealers and buyers are unwilling to give exact figures.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 20.—Copper is quiet, though fairly strong; lead is quiet, but becoming firmer; zinc is active and rising.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Jan. 13	56.87	Dec. 8	55.54
" 14	57.00	" 15	55.66
" 15	56.87	" 22	54.23
" 16 Sunday		" 29	54.05
" 17	56.37	Jan. 5	55.67
" 18	56.37	" 12	56.62
" 19	56.62	" 19	56.68

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	57.58	48.85	July	54.90	47.52

May	58.21	49.87	Nov.	49.12	51.88
June	56.43	49.03	Dec.	49.27	55.34

Apart from small fluctuations, silver remains steady. India has bought at rising prices. European and English orders assisted firmness.

Silver market conditions in China are discussed in the January Bulletin of the Canadian Mining Institute, by G. G. S. Lindsey. At the end of last August there was $2,000,000 Mexican dollars in the banks there. This is an accumulation due to customs and salt revenues, pledged for loans awaiting distribution from foreign banks. Small banks are to be opened. New currency is needed. The country is not a large silver consumer.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915.

May	12.97	18.71	Nov.	11.75	18.88
June	13.60	19.75	Dec.	12.75	20.67

Exports during the week ended January 1 were 26,586,160 lb., worth $5,318,134. France got 12,511,269 lb. of this. Imports amounted to 2,197,661 lb., valued at $371,465. Cuba sent 518,560 pounds.

The 'American Metal Market' estimates stocks at the end of 1915 as 240,000,000 lb., an increase of 67,000,000 lb. compared with a year ago.

In 1915, Michigan companies made a total profit of $20,000,000; the cost was 9c. and revenue 17c. per pound. The January output will be about 5,000,000 lb. less on account of bad weather.

Wages at Butte have been raised 25c. per shift.

Braden produced 3,826,000 lb. in December. The Chile Copper Co. is to prepare for a 300% increase in yield, available in 1920.

Eastern Metal Market

New York, January 14

Taken as a whole, the market shows a somewhat irregular tendency. The big buying of copper has ceased, for the time being at least. The market is adversely affected by Great Britain's evident intention to protect its interests, and curb speculation. The same is true of lead, which has been quiet in New York, despite offerings at concessions. Spelter has been fairly steady, but not active, although spot and prompt metal has been taken. Tin has been dull, not only because consumers have lacked interest, but because of difficulty in getting licenses to ship from England, and unusual delays in cable communication. Antimony is dull, scarce, and firm. Aluminum continues to grow easier for no apparent reason.

As for domestic business in general, so far as metal working lines are concerned, a betterment is indicated on all sides by the steady and diversified demand for machine-tools. The ship-yards have orders aggregating $100,000,000 on their books, calling for some 700,000 gross tons of merchant vessels, to say nothing of Government work. Several vessels cannot be delivered for three years, and many authorities believe the yards will be busy for five years. The Seattle Dry Dock & Construction Co. will build two vessels for the Atlantic coast trade because it can deliver them more quickly than can any yard on the Atlantic seaboard. In the East, the railroad freight embargoes continue to hamper business, especially the foundry trade. The steel trade continues to boom. In December the Steel Corporation's unfilled orders increased 616,000 tons, making the total 7,800,000 tons, the largest since early in 1913. The Corporation, and most of the independents, have advanced the wages of common labor 10%. Mills are asking up to 2.50c., Pittsburg, for plates.

COPPER

In the past few days the copper market has been somewhat uncertain, and in many minds there is a belief that quotations have gone as high as they are likely to go for the present. The producers are asking from 24 to 24.25c., 30 days, delivered. Some of them say business is still fair, while others say there is but little doing. Second-hands, in the early part of this week, offered substantial concessions to get business, but succeeded in placing only a few hundred tons. On January 13, the London quotation for standard advanced £2 2s. 6d., to £87, whereas in the past few days it had been losing strength and had declined £6. After the advance, second-hands thought better of the market and their offerings were withdrawn. It was said they had sold down to 23.12½c. cash, New York, but their minimum quotation January 13 was 23.50c. Not much was taken at cut prices. The London quotation for electrolytic has stood fast at £114, although Great Britain has fixed £100 as the maximum price which munition makers should pay, its intention being to curb speculation. France has been a good buyer recently. A short time ago when the recent movement was at its height the wire-drawers and other domestic consumers were heavy purchasers, but since that time the buying has been entirely on the account of the munition makers. In this connection the fact will bear repetition that many of the War buyers know little or nothing about the working of copper. Some of them already have met with costly troubles in the execution of their orders, and some of the contracts are being turned over to other concerns to complete. Certain users of copper are expecting that considerable metal, originally intended for War purposes, will find its way to the general market. One large concern which had orders for shells valued at millions has practically collapsed, and it is no secret that others are having their troubles. Reliable engineering firms will make a great deal of money out of War orders, but the inexperienced individuals that rushed into the game, declaring that with an order in hand they could raise any amount of money, and that with money they could buy all the brains that were needed, also do anything, no matter how short the time, are not quite so enthusiastic. European stocks have continued to diminish, as indicated by the following statement of Henry R. Merton & Co., Ltd., London, under date of December 17: "The European visible supplies on December 15 amounted to 23,493 tons, as against 26,068 tons, on November 30, thereby showing a decrease of 2575 tons. The actual stocks in England and France shrunk 2550 tons, and now amount to only 12,495 tons (December 15)." Exports in the first 14 days of January totaled 11,051 tons.

ZINC

Except for spurts of demand for spot and nearby deliveries the zinc market has been continuously dull and uninteresting. Sellers do not appear to have much early metal to offer, but what comes out is taken steadily. Considerable surprise has been expressed because the market did not become more active in sympathy with copper, and the only explanation is that consumers filled up a few weeks ago. At no time has the quotation been far from 17.50c., New York, though a stronger tendency developed late this week. The galvanizing trade is staying out of the market to a great extent, and its absence was accentuated by two or three violent strikes at steel plants at Youngstown, Ohio. There was fear that the strikes would become widespread, but a wholesale advance of 10% in the wages of laborers appears to have quelled the trouble. Prompt metal was quoted on January 13 at 17.50c., New York, for spot; 16.55c. for February; 15.75c. for March, and 14 to 14.50c. for second quarter. Exports in 11 days of January totaled 1929 tons.

LEAD

The most important development in lead since the last report, is the announced intention of Great Britain to halt speculation which is working to the detriment of her munition makers, and to the disadvantage of the Government itself. This news caused the London quotation for spot to decline on January 12 from £31 to £29 5s. (off £1 15s.) The New York and St. Louis markets quickly reflected the weakness abroad, particularly at St. Louis, and although the leading interest adhered to its quotations of 5.90c., New York, and 5.82½c., St. Louis, second-hands were willing to sacrifice a few points to get business. For some days the domestic market has been very dull and unsettled. The exports in fourteen days of January totaled 3245 tons.

TIN

The market has been dull to a point of stagnancy for several days. Not only have domestic consumers shown little interest, but trading has been hampered by events abroad. News comes that licenses to ship from England are obtained with difficulty by firms in whom the British government does not seem to have complete confidence. Again, cable messages have been subject to unusual delays, frequently arriving too late for action to be taken on them. The spot quotation on January 6 was 42.25c., and January 12, 41c. Up to January 14, 3075 tons had arrived in the month, and there was 5365 tons afloat.

ANTIMONY

The market has been extremely dull, but the scarcity of nearby supplies has been a sustaining influence, and quotations range from 41.50 to 42c. for Chinese and Japanese grades. The American product is quoted at the same figure.

MINING DECISIONS

Oil Lease Held a Mere License

An agreement in the form of a lease for a term of years granted the right to explore for oil and gas, and provided that unless a well were drilled within a year, a rental of $2.50 per acre per year should be paid thereafter. Held, such an agreement is more like a license than an estate in land, and may under its terms include a forfeiture without notice, if the rental is not paid or the well drilled in the specified time. In the case of an option, time is of the essence of the contract, unless the contract expressly provides it shall not be.

Mitchell *v.* Probst (Oklahoma) 152 Pacific, 597. October 19, 1915.

Miner's Liens—Prior to Mortgage

A mortgagee in a mortgage executed subsequent to the statute giving laborers and material men a preference lien, is not deprived of his property right without due process of law, because the liens of mine laborers and material men attaching subsequent in date to the date of his mortgage are given preference over the mortgage. When the liens are attached by reason of obligations incurred in the mining operations of a lessee, no personal judgment can be entered against the owner.

Haines Commercial Co. *v.* Grabill, et al. (Oregon), 152 Pacific, 877. November 16, 1915.

Oil-Wells—Draining Adjacent Land

Where oil-wells are driven in such close proximity to the division line that they drain oil from the adjoining land, such operations, in the absence of special circumstances or relations between the parties, afford no basis for a claim to a share in or accounting for the oil so produced, or for a receivership thereof.

Gain *v.* South Penn Oil Co. (West Virginia), 86 Southeastern, 883. October 19, 1915.

Oil Lease—Additional Royalty Clause

Where in a deed conveying oil and gas privileges on a stated consideration, it is further provided that the grantee is to pay the grantor additional consideration "within 90 days after a well for oil and gas is drilled on the land and oil produced in pipe-line in paying quantities," there is no obligation for payment of the additional consideration if a well is drilled and gas alone produced.

Ball *v.* Freeman (West Virginia), 87 Southeastern, 91. November 16, 1915.

Oil Corporation—Not to Own Railroad

Statutory authority to erect, build and own tank-cars does not authorize an oil company to build and operate a railroad even though such railroad be used in the operation of its business.

Continental Trust Co. *v.* Brown (Texas), 179 Southeastern, 939. November 17, 1915.

Injury to Miner—Liability of Owner

An employee of a tunnel contractor was killed by coming in contact with a defectively insulated electric cable in an air shaft where he was not supposed or required to go. Held, that no liability attached to the mine-owner who had contracted with the employer of the deceased to drive the tunnel.

Patterson *v.* Alabama Fuel & Iron Co. (Alabama), 69 Southern, 952. November 18, 1915.

Note: This decision would have no weight in those States which have adopted compensation acts.

COMPANY REPORTS

TONGKAH HARBOUR TIN DREDGING CO., N. L.

This company's report for the year ended September 30, 1915, is of much interest. The head office is at Hobart, Tasmania, and the field of operations is at Puket, Siam. The title explains the metal produced and the method of extraction. The general manager is Eliot T. Lewis, with G. H. Symons as assistant.

As No. 1 dredge sank and was of no further use, only five boats were operated. They worked a total of 27,369 hours, digging 2,968,600 cu. ft., yielding 0.953 lb. tin oxide per yard, at a working cost of 8.926c. per yard. The time was less, yardage more, yield less, and costs less than in the previous year. The tin-dredging plant returned 1262.3 tons of oxide averaging 72.5% metal.

The net profit was $195,000, of which $110,000 was paid in dividends. Adding the previous balance, the credit is now $340,000. Dividends to date amount to $1,090,000, equal to $7.92 per share.

ASHANTI GOLDFIELDS CORPORATION, LTD.

This company operates in West Africa, and its report is for the year ended June 30, 1915. The ores mined have been the subject of considerable discussion, on account of the graphite contained, and its effect on cyanidation.

The consulting engineer reported as follows: The Ashanti, Ayeinm, Old Chief, and Tom Collins mines produced a total of 138,316 tons of ore. Reserves amount to 433,900 tons averaging $21.55 per ton, an increase of $860,000 in value. Ventilation of the Ashanti is not solved yet. The Old Chief and Tom Collins are about exhausted. Labor and fuel supplies were plentiful. The gas-electric sets are working well, the cost per horse-power day being 44 cents.

The central mill treated 109,287 tons by dry crushing, roasting, and cyanidation, for a yield of $1,930,000, with 93.1% recovery; the Côte d'Or mill treated 29,029 tons, yielding $217,000, with 83.9% extraction. A variety of processes are used in the latter.

The year's profit was $770,000, of which $720,000 was paid in dividends. The credit balance is $340,000.

Mining cost $2.46; treatment, $3.24; and general expenses, $1.12, a total of $6.82 per ton.

CONSOLIDATED MINING & SMELTING CO. OF CANADA, LTD.

The report of this British Columbian company covers the year ended September 30, 1915. The general manager, R. H. Stewart, briefly gave the result of operations.

Development in nine mines totaled 21,067 ft. of narrow work, and 26,415 ft. of diamond-drilling. Ore reserves remain practically as before. Work is underway at 2400 ft. depth in the War Eagle mine, by means of a cross-cut from the Center Star shaft. Some small properties were purchased.

New plant cost $334,909, mostly at the Trail smelter. Considerable testing was done on the production of electrolytic zinc, and a 25 to 35-ton plant is about complete. The Sullivan mine can supply the ore for this process.

Custom ore received was 57,251 tons, against 72,098 tons in the previous year. The smelter treated 447,064 tons of ore, yielding 148,891 oz. gold, 2,230,500 oz. silver, 40,177,910 lb. lead, and 5,306,184 lb. copper, valued at $6,898,744. After writing-off $192,479 for depreciation, the profit was $795,411. Four dividends absorbed $464,398. Adding this and last year's surplus the balance is $2,058,300.

Since 1894 the output is 4,372,886 tons ore, 1,610,903 oz. gold, 22,247,832 oz. silver, 374,091,124 lb. lead, and 63,196,978 lb. copper, valued at $73,402,078.

RECENT PUBLICATIONS

Mine Safety Rules. Issued by the Industrial Accident Commission of California. P. 123. Ill., index. State Printing Office, Sacramento, 1915. These rules were effective on January 1, 1916. The book was noted in the Press of December 25.

Methods for the Examination of Bituminous Road Materials. By Prévost Hubbard and Charles S. Reeve. Bulletin 211. P. 48. Illustrated. U. S. Department of Agriculture, Washington, D. C., 1915. Of practical value to road engineers.

Annual Report of the Superintendent, U. S. Coast and Geodetic Survey, to the Secretary of Commerce, for the fiscal year ended June 30, 1915. P. 156. Maps, index. Washington, D. C., 1915. There is a lot of interesting matter in this report, a good deal covering work done in and proposed for Alaska.

Extraction and Recovery of Radium, Uranium, and Vanadium from Carnotite. By Charles L. Parsons, R. B. Moore, S. C. Lind, and O. C. Schaefer. Bulletin 101, mineral technology 12. P. 121. Ill., plans, index. U. S. Bureau of Mines, Washington, D. C., 1915. A brief outline of this process was given in the Press of December 25.

Annual Report of the Director of the Mint for the fiscal year ended June 30, 1915; also report on the production of the precious metals in the calendar year 1914. P. 304. Ill., index. Washington, D. C., 1915. This publication deals with gold and silver work at the Mints, foreign gold, money, consumption of precious metals, output of the principal countries, etc.

Mineral Resources of California. Advance chapters on Amador, Calaveras, and Tuolumne; Colusa, Glenn, Lake, Marin, Napa, Solano, Sonoma, and Yolo; Del Norte, Humboldt, and Mendocino; Fresno, Kern, Kings, Madera, Mariposa, Merced, San Joaquin, and Stanislaus; and Shasta, Siskiyou, and Trinity counties, by various authors, field assistants with the California State Mining Bureau. Total pages, 980, with illustrations and indexes. By writing to the Bureau at the Ferry building, San Francisco, these publications may be procured at from 25 to 50c. each. In the Press of January 1 they were given considerable space.

Origin of the Zinc and Lead Deposits of the Joplin Region, (Missouri, Kansas, and Oklahoma). By E. Siebenthal. Bulletin 606. P. 283. Ill., maps, index. U. S. Geological Survey, Washington, D. C., 1915. The region, generally known as the Joplin district, has been the subject of a number of geological investigations. In studying the ore deposits of this area, Mr. Siebenthal reached certain conclusions regarding the genesis of the ores which are somewhat at variance with those reached by some other investigators, but are in general confirmatory of the findings of the U. S. Geological Survey's earlier work. In these investigations, the original source of the metals has generally been the subject of much speculation and study. Analyses of large quantities of material have shown the general presence of measurable quantities of lead, zinc, and copper in the pre-Cambrian crystalline rocks, in the Cambrian and Ordovician limestones, and in the Mississippian limestones, and it is also known that the Pennsylvanian shale in a few places carries appreciable quantities of lead and zinc. These rocks comprise all the geologic groups that make up the Ozark uplift, and each group has been considered the immediate source of the metals by one or more writers on the geology of the ores. The present report, the result of several years' study, likewise holds that the ores were deposited by ascending artesian solutions which derived the metals chiefly from the Cambrian and Ordovician limestones.

Commercial Paragraphs

The Fort Wayne Electric Works of the General Electric Co., Fort Wayne, Indiana, has issued two bulletins describing its type H and M 2 demand indicators.

At Denver, Colorado, the Sutton, Steele & Steele Manufacturing, Milling & Mining Co. has its new demonstrating mill ready to receive all kinds of common and rare ores. Storage-bins have a capacity of 700 tons. The mill is entirely automatic. The patented machines concentrate dry.

Snyder Electric Furnace Co., Chicago, Illinois, has recently published an attractive illustrated booklet on the application of electric furnaces to the manufacture of steel. The application of the electric furnace is finding favor in a great many localities, and many advantages are claimed for the Snyder furnace over other types of furnaces.

Bulletin No. 9 of the Electric Weighing Co., New York, whose Western agents are the Mine & Smelter Supply Co. of Salt Lake City, Denver, and El Paso, describes the Messiter conveyor scales. This machine has been tested under working conditions for over three years. It weighs material while being carried on belt, pan, or bucket-conveyors. Weights and prices are given.

The January issue of *Mine and Quarry*, published by the Sullivan Machinery Co., Chicago, contains several interesting items, including 'Rapid Sinking at the Newport Mine, Michigan,' 'American Drills in an Italian Tunnel,' 'A Mechanical Drill Smith,' 'Deep Mining with Ironclad Coal-Cutters,' 'The Dorchester Tunnel Under Boston Harbor,' 'The Air-Feed Drifter,' and 'Core-Drilling at the Hollinger,' Ontario. These are authoritative articles.

The Utah Karns Tunneling Machine Co. of Salt Lake City, recently perfected a heading machine for rock tunnel work. The machine puts in a 12-in. cut hole 15 ft. into the heading, and eases the ground so that 15 ft. can be broken down in a round in any size heading in an 8-hour shift. Small drills are used in connection with the machine, all holes being drilled the 15 ft. No powder is used in the 12-in. hole, but is put in the small drill holes and the whole mass breaks into the relief hole.

In its flotation oil Circular No. 11, the Pensacola Tar & Turpentine Co., of Gull Point, Florida, states that the list of oils has been greatly reduced. It is considered that there are too many oils, and most of the business will be done on one abundantly produced medium-priced oil, such as No. 350, which contains most of the other oils. This is a special crude wood oil, costing 24c. per gal. in tank-cars, or 27.5c. in barrels. The No. 80, a crude pine oil, 33c. in bulk, is a useful flotation medium. No. 1580 is suitable for lead, silver, zinc, and other complex ores. Doped oils are briefly discussed. One apparently good oil consisted of a skillful mixture of mineral oil, turpentine, and rosin. Plain distillation tests are useless for analysis of such material.

The Anaconda Copper Mining Co. has placed an order for six more 10-ft. diam. by 4-ft. cylindrical length Hardinge ball-pebble mills, making a total of 56 conical mills for the new plant, 48 of which are already in operation. The Hardinge company reports that the 10-ft. mills are direct connected herring-bone gear driven, operating with less than 75% of the power which was originally estimated to be necessary.

V. A. Stout, San Francisco representative of the Hardinge Conical Mill Co., announces the following sales of Hardinge mills for 1916: Natomas Co. of California, six 4½-ft. diam. by 16-in. pebble-mills for re-grinding concentrate on the various dredges; Treasure Mining Co., one 4½-ft. diam. by 16-in. ball-mill, and two of the same size as pebble mills for its new plant near Amador City.

EDITORIAL

T. A. RICKARD, Editor

INDEX to our Volume 111, covering July to December, 1915, is now ready. Copies will be mailed to subscribers upon application.

PRICES of metals continue to rise, as will be seen by reference to the interesting letter from our New York correspondent. Copper at 25.37, zinc at 19.25, and lead at 6.10 are figures to warm the miners' heart.

FORTUNATELY pan-amalgamation has been superseded at most of our mines, otherwise the present price of quicksilver, at $275 per flask, would be distressing to the miner. In pan-amalgamation an average of about 1¼ pound of quicksilver is used per ton of ore; at present prices that means $4.65 per ton.

FLOTATION is to be applied to the low-grade copper ore of the Spassky mine, in Siberia. Mineral oil is to be used. Some changes will be made in the smelter to prepare for the treatment of the concentrate. We note a decided interest in flotation at Cobalt, where the process is likely to be applied to low-grade silver ore and tailing.

MISSOURIANS complain that the big zinc output of their State, notably from the Joplin region, is treated at smelters in other States. Now that acid leaching and electrolytic precipitation have proved an economic process, why should not the Missouri zinc concentrate be treated in domestic reduction works? They have the water-power.

ACCORDING to statistical evidence, the total foreign trade of the United States in 1915 was only 1.1% of the domestic commerce of the country. The actual increase in external trade last year, extraordinary as it was, shrinks by comparison with the internal growth, for the foreign increase was $1,450,000,000 as against a gain of $58,000,000,000 in the home trade.

IN the course of a recent interview in Paris the French economist M. Paul Leroy Beaulieu expressed the opinion that the War will not plunge the belligerent nations into bankruptcy, or anything like it. Undoubtedly the pauperizing effect of the Great Calamity has been exaggerated by failure to realize how much of the abnormal expenditure is distributed among the people of the respective countries at war; moreover, the richness of these countries and their powers of recuperation are vastly greater than is generally assumed, on the basis of precedent wars in periods of early industrial development. M. Beaulieu predicts remarkable manufacturing activity at the close of the War, about a year hence, and commercial rivalry among the nations, leading to protective tariffs, even in England, and yet higher tariffs in the United States.

DECISION in the case of the Elm Orlu Mining Company against the Butte & Superior Copper Company has been handed down by Judge Bourquin at Butte in favor of the plaintiff, although the decree is in the nature of a compromise, out of which the Elm Orlu gets a recognition of priority of location over the Black Rock claim. As our readers are aware, Mr. W. A. Clark controls the one company and Mr. D. C. Jackling the other.

RESUMPTION of work at the three big copper mines in the Clifton-Morenci district of Arizona is announced, the men on strike having decided on January 24 to accept the higher wages based upon the rise in the price of copper. We congratulate the companies and the miners both on the adjustment of their quarrel and more particularly on having eliminated the Western Federation of Miners as a factor in their economic conditions.

A RECENT issue of the *Saturday Evening Post* contains an article describing the underground workings of a copper mine. We quote from it: "This maelstrom in the stone, its vortex lost in shadow, appeared yawning like an open throat. I was struck dumb on the very rim of that ominous cavity. It seemed to me as if this rift was a sort of heartless ruin caused by a landslip or by some disaster unforeseen. It was nothing more or less than a stope." We are reminded of the young woman who called the weather "absolutely revolting" and found a potted-ham sandwich "positively divine."

ON January 24 we received the news of the sudden death of John A. Hill, the publisher of a group of trade papers, including the *Engineering and Mining Journal*, the *American Machinist*, *Power*, the *Engineering News*, and the *Coal Age*. John Alexander Hill was a commanding personality, rough and forceful, honest and honorable, with all the superb initiative that marks a captain of industry. Starting life with no education save the ordinary schooling obtained by a boy up to 14 years of age, he entered a printing office and employed his spare time to equip himself for a useful career. By sheer force of industry and character he won a way not only to fortune but to a position of great influence. He used that influence well, although we think he might have

employed it even more to the public good if he had received a more generous mental training. That may be; it is certain that men of his dynamic type are responsible for the technical and industrial development of our time and generation, they do a splendid share of the world's work, and the world is impoverished when their activities cease. We desire to honor the memory of a strong, useful, and honorable man.

TIN is now being smelted in the United States, in the smelter just built by the American Smelting & Refining Company at Perth Amboy, New Jersey. This plant is intended mainly to treat Bolivian tin concentrate, at the rate of 750 tons per month. In order to produce a metal suitable for the tin-plating industry the product of the smelter will be refined electrolytically. To assure an adequate ore-supply, the company will make liberal advances on shipments from the mines. Unfortunately the block in the Panama Canal has interfered with the transport of Bolivian concentrate, but this is temporary. A more serious danger is the threat of a differential tariff in Bolivia as between *barilla*, or 60% concentrate, and bars of metal. Such a step may be taken by the Bolivian government with the hope of encouraging the domestic reduction of the ore. If this happens, the smelter at Perth Amboy will be the victim of the same ill fate that befell the tin smelter built at Bayonne in 1903. The latter was intended to treat tin concentrate from the Malay peninsula, and it was just ready to start when the government of the Federated Malay States imposed a duty of $30 per picul, or 133⅓ pounds, on all tin ore exported. This impost, plus an older tax equal to 12% of the value of the tin, killed the export and at the same time put a quietus on tin smelting at Bayonne. The plant was dismantled. According to information coming from La Paz an effort is being made to induce the Bolivian government to subsidize a domestic tin smelter, thus saving the freight on the 40% of impurities in the concentrate, but the affair appears to be half-baked. We hope nothing may arise to disturb the success of the new smelter at Perth Amboy, and we conclude that the Guggenheim directors ascertained the intentions of the Bolivian government before committing themselves to the scheme. Bolivia produces about 40,000 tons of 60% tin-stuff per annum, while the United States imports about 44,000 tons of metallic tin annually, this being equal to 40% of the world's consumption.

WE publish an extremely interesting letter from Mexico City in which an observant correspondent expresses himself frankly concerning present conditions in Mexico and the causes leading thereto. While we do not agree with all the conclusions stated, it is obvious that the writer knows what he is talking about and is well qualified to state his own point of view—one by no means optimistic. It is not likely that any American long resident in the country can be other than depressed by the persistence of political chaos. What he says is largely in accord with the best information previously available. The reference to syndicalism and the Casa del Obrero Mundial, or House of the World's Workers, is timely, more particularly if read in conjunction with an article by Sr. Carlo de Fornado on the 'Great Mexican Revolution' in the *Forum* of November last. Evidently this representative of the I. W. W. is an organization that represents the most radical elements in the revolutionary party. As such it is likely to become less violent in its program when the Carranzistas find that government cannot be conducted on vaporous pronouncements, and that their promises to make a new world for the peon require time for fulfillment; in short, that evolution from political chaos is not done in a hurry, any more than development from elemental chaos. Indeed the most liberal-minded man may well be dismayed at the prospect of changing a peonage dominated by military adventurers into a self-reliant democracy disciplined by representative government. The problem in Mexico is much the same as that in China: an effort to effect a true political revolution under the shock of impact with nations several centuries more advanced in the complex art of living. What Mexico and China both need is a benevolent despotism pending the education of the people and their adjustment to modern conditions. Unfortunately despots, even if benevolent at first, do not remain so long, causing struggles for power amid which the delicate fruits of humanitarian ideals are crushed under-foot, to make room for brute force, corruption, and thinly disguised slavery.

To Those in the Trenches

It will interest our readers to know that the group of American mining engineers resident in London joined in sending a box of Havana cigars to each of 98 British mining engineers in the trenches. This was done as a New Year greeting. With the gift the following note was transmitted:

Jan. 1, 1916.

To the British Mining Engineers
at the Front.

Dear Fellow Engineers,

Please accept this as a small token of our earnest sympathy and our admiration of the fine spirit with which you are meeting the supreme need of the hour. The War may disarrange, but it cannot break the bonds of our common profession; and our sincere hope is that whatever sacrifices the New Year may exact, you personally may come through safe, and that long before the year be ended, you may be able to return to the regular duties from which you can so ill be spared.

American Mining Engineers
Resident in London.

In addition a verse was attached:

"It's the same sort of honest devotion
That's always stood by you before;
When you solved metallurgical problems,
When you put down the deep-level bore,
When you fought with disease in the Tropics,
Won out in the strike at the mines,
It's the same sort of honest devotion
That blows up the enemies' lines."

To the first the initials H. F. B. might have been signed, and to the latter those of E. R.

The act and the manner of it render comment almost superfluous. Even those whose sympathies are enlisted on the other side will appreciate the incident. For ourselves, although we do not like hyphens, it seems that when the hyphen takes the shape of a real cigar, the link between Anglo and American is one to which even the most doctrinaire neutral cannot object. "In the far savannahs a talisman grows that makes all men brothers," and for that reason a fragrant smoke serves as the best expression of the mutual understanding and good-fellowship that exists between the mining engineers who share the same language, the same technical literature, and some of those great imponderables on which our notions of life and happiness depend.

Flotation Litigation

In our issue of December 18 we outlined the present status of the litigation over the flotation patents, referring to the two principal suits, but we failed to note a third suit, arising from the Butte & Superior case. The first suit was brought by Minerals Separation against Mr. James M. Hyde personally, although his operations were conducted on behalf of the Butte & Superior Copper Company. After Minerals Separation had obtained a decision in their favor from Judge Bourquin in the District Court at Butte, they brought a suit against the Butte & Superior, and asked the Court to grant a preliminary injunction enjoining that company from continuing the use of flotation. As our readers probably are aware, a preliminary injunction is one granted in advance of the trial of a case, and is granted upon a preliminary showing, generally in the form of affidavits. In this country a preliminary injunction is rarely granted in favor of a patent that has not previously been adjudicated. In other words, the presumption of validity arising from the mere grant of a patent by the Patent Office is not strong enough to warrant a court in granting a preliminary injunction, that is, granting the injunction without having a regular trial and giving the defendant full opportunity to present his case. In the suit against the Butte & Superior company, Minerals Separation proceeded upon the theory that a full trial had previously been had in the Hyde case as a result of which the Court had found patent No. 835,120 valid and infringed by the Hyde operations, which operations were in reality the operations of the Butte & Superior. There was some force in this position assumed by Minerals Separation. But when the application for preliminary injunction came before Judge Bourquin for argument, the defendant made a series of demonstrations before the Court showing the formation of a froth with large quantities of oil, that is, quantities considerably larger than 1%. As a result of these demonstrations, Judge Bourquin refused to grant a preliminary injunction, thus seeming to indicate a lack of certainty on his part as to the correctness of his decision in the Hyde case. The Judge made a sort of compromise decision. He decided that if the Butte & Superior company would furnish a bond in the amount of $75,000, said bond running to Minerals Separation, and payable in the event that the decision was finally in their favor, he would not grant any preliminary injunction. In case Butte & Superior failed to file such a bond, the Judge decided that he would grant a preliminary injunction, provided Minerals Separation filed a bond in the sum of $125,000, payable to Butte & Superior in case that company was finally successful in the suit, as indemnity against the loss arising from having the mill shut-down. In other words, the Judge decided that he would not grant a preliminary injunction if Butte & Superior filed a bond, and even if that company did not file a bond, he still would not grant an injunction unless Minerals Separation filed a still larger bond to protect Butte & Superior against injury resulting from the mill being closed-down, and the final decision being in their favor. The Butte & Superior company did file a bond in the amount of $75,000, and, in compliance with a further provision of the Court's ruling, has since filed monthly reports of its operations in Court. After the above proceedings the Court of Appeals at San Francisco reversed the decision of Judge Bourquin in the Hyde case, holding the patent invalid. Apparently this would have warranted, if not compelled, the lower court to cancel its ruling in the Butte & Superior case, inasmuch as the bond in that case was filed upon the presumption that was upset by the Court of Appeals. However, no action was taken in the Butte & Superior case along this line, the company being willing to let the matter rest and to leave its bond in force until the Hyde case is finally decided.

Patents

A patent is the grant by a Government of the exclusive privilege, for a limited period, to make, use, or sell an invention, or to authorize others to do so. In order to record this right, and to warn others from infringing it, the inventor prepares a description of his invention and specifies his claims of originality in a written statement that is lodged at the Patent Office. Right to a patent can be based either upon originality of apparatus or originality of use. In practice, however, the inventor usually discloses only so much of the design of his machine or of the use to which he puts it as will justify his request for a monopoly. In consequence, the language of a patent description or of its claims is often cryptic intentionally, so as to give the minimum of information to possible infringers. Moreover, the tendency to regard patents as an unnecessary interference with industrial initiative and to look upon the royalties imposed by patentees as an irritating exaction has caused them to be classed with vexatious monopolies to evade which is not culpable, if indeed it is not creditable. In short, the use and abuse of this form

of privilege has produced a low state of public morality, the blame for which is widely distributable.

Two aspects of the problem present themselves to any one wishing to be fair. On the one hand it is said that the patentee does not disclose frankly what it is he has discovered or what use he intends to make of his discovery, thereby affording the infringer an excuse for claiming innocence of any trespass. On the other side the inventor can reply that the incompleteness of the disclosure is necessitated by self protection, having regard to the flagrant disregard of property rights evinced by the public and applauded by the press. As between these opposite statements the onlooker will observe that the granting of patents has not done away with trade secrets, and it is often a nice question whether an inventor shall patent his process, disclosing his method, or keep his process secret and protect himself by a copyright name. If he be a manufacturer himself, this may prove the wiser course. 'His Master's Voice' is worth more than the Victor patent. A middle course may be followed, disclosing enough to procure the essential patent and then copyrighting a label for commercial identity.

Again, it is said that the effort to protect himself is made increasingly costly to the patentee, who is often deprived of his profit by sheer financial inability to defend himself, so that he has to submit to being robbed of the privilege obtained by him legally from the Government. To that the reply is made that the whole world is much in the same fix; the patentee is like the rest of us, who have to arrange for the necessary capital as best we can. Not until the millenium will a poor man be able to compete successfully in business with the rich. As they say in Mexico: *las minas son para los ricos*, if you are a poor man you have no business with a mine. This *non possumus*, of course, is an evasion of the problem, for the end in view is the rewarding of the inventor without creating an incubus upon industry. It has been suggested, for example, that the Government, having rewarded the inventor with a privilege, should protect him in the exercise of it; but that is untenable, one might as well ask the Government to protect a man in the ownership of a homestead. Not until paternalism has been raised to the *n*th degree will anything of the kind be possible. So we come to the patentee who is unable to exploit his patent commercially and feels compelled to sell his rights for a relatively small sum to an individual or a corporation having adequate funds for the exploitation of the patent, whereupon the monopoly passes into the hands of persons who may proceed to exact royalties of an exorbitant character or to impose conditions that render the use of the invention prohibitive. Thus, it is claimed, a proper reward rarely comes to the inventor himself, but to a patent-owning corporation, which waxes rich on royalties. It may be objected that the royalties are not paid by the ultimate consumer, but as a matter of fact, they add to the cost of the article, and in that way he does bear the freight. In the case of metallurgical patents, such as, of course, we have in mind, the royalty comes out of the miner's settlement for his ores and out of the dividends of the mine owner. But, if the royalties are excessive, they, like usurious rates for money, will create dangers from which moderate demands are exempt. In the end, a law is inoperative against a unanimous public sentiment. That point has not been reached, but it is true that the studied obscurity of patent specifications, the confusing character of judicial decisions, and the excessive demands, not of inventors themselves, but of patent-owning corporations, have awakened a keen feeling of protest against the whole system, causing a set of conditions detrimental to metallurgical initiative, for example.

It has been questioned whether the monopoly implicit in a patent is in the public interest. Divided as we may be in our opinions on this matter, we answer in the affirmative, because we recognize the advantage of having ingenious men on the alert to discover improvements to their benefit, much of which accrues to the community in a measure outweighing all the discomforts and scandals incidental to patent squabbles and legal fiascos, which represent the froth on top of the inter-actions between diverse activities. Comparatively few patents result in litigation, while the hope of a patent spurs many men to work that promotes the development of ideas and the improvement of apparatus. To abolish the granting of patents because one or two patentees are unreasonable would be on a par with the abolition of marriage because divorces happen. We may trust public sentiment and the adjustments of business to act as a corrective. The conclusion is that no other method is available, and no other is needed, as yet.

America is a nation of inventors: we must have a liberal patent law. The typical Yankee boy is Darius Green with his flying-machine. Every lad who works in a factory fancies himself an inventor and exercises his wits to analyze the operations in the factory. His spare time is spent in the wood-shed working at a model. Even if his invention come to nothing, he has improved his quality as a workman and made himself more valuable both to his employer and to himself. The nation gains thereby; the conditions of life are ameliorated by the inventor's ambition to better himself. If we do not travel in an ox-cart by the light of a pine torch, we owe the improvement to the inventor: to Winans, Westinghouse, Edison, Tesla, and a host of others who took out their patents and did their work for what there was in it. Morse, Field, Bell, and Marconi perfected their methods for the transmission of thought in order to gain an honorable profit. Barbed-wire, gang-plows, grain-headers, well-drills, turbines, and other patent machinery have populated the land with progressive agricultural people, who are not peasants. He who makes two blades of grass grow where but one grew before is declared to be a benefactor of his race, but he who does this doubles his crop of hay. Let the man who would abolish the Patent Office pack his blankets, his frying-pan, and his tallow candle, and, calling his dog, take to his log cabin in the tall timber of the Sierras.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

American Potash

The Editor:

Sir—Referring to the article in your issue of November 27, to which my attention has been drawn, I beg to say that while others have been advancing various theories for the production of potash on this Coast, its actual manufacture has been established by the Inyo Development Co., at Keeler, California. The constituents of the water of Owen's lake render it one of the most interesting chemical problems in California. Its peculiar composition has long attracted the attention of scientists and chemists. For 30 years, before there was any chemical industry to speak of in California, crude carbonate of soda was manufactured by this company on the borders of the lake near the little town of Keeler. Then about 20 years ago followed the making of soda-ash, which is now one of the most important industries in this part of the state.

The chemical composition of the solids of the water of Owen's lake is, according to a Government bulletin:

	%
Silica	0.28
Alumina, lime, and magnesia	0.13
Sodium borates	0.63
Potassium chloride	4.07
(Other analyses show from 2.80-4.25%, average 3% KCl.)	
Sodium chloride	38.16
Sodium sulphate	14.38
Sodium carbonate	34.95
Sodium bicarbonate	7.40

The lake-water contains approximately 8% of solids, but the contents vary considerably according to the season.

Solar heat is used for the evaporation of the brine to crystallize the carbonate of soda. To manufacture it more than 96% Na_2CO_3 pure, much experience is required.

If the evaporating is properly conducted, a great part of the carbonate of soda can be produced as a crystallized salt of the above-named standard. This will serve to furnish, by melting and grinding, a high-grade soda-ash, while the rest of the soda remains in liquid. After all the carbonate has been precipitated, the remaining liquor is termed 'spent water.' This spent water has hitherto been wasted by returning it into the lake, but will now be used for the manufacture of potash manure salt.

The chemical analyses of water samples taken from the different vats at different times vary considerably in the proportion of their components. A test of the solids of this water showed the following results:

Specific gravity of the water 1.3249 at 20° C.

Solution distinctly alkaline, total residue on evaporation 505.2 grams per litre.

The solids contain:

	%
Sodium chloride	47.84
Potassium chloride	3.41
(between 3.20-5.50% KCl.)	
Sodium tetraborate	2.83
Sodium sulphate	16.42
Sodium carbonate	29.21
Silica aud alumina	0.24
Calcium carbonate	0.13
Magnesium carbonate	0.07

As a rule there is about 50 to 100% more KCl in this 'spent water' than in the lake water.

In warm weather and under good supervision, the crystallizing of the soda takes place in such a way that the spent water will contain more chloride of sodium and potash, and less carbonate, than indicated by this analysis.

Solar heat is used to concentrate the liquor, to produce a potash salt of a higher percentage and to remove the main part of the other constituents.

It might be mentioned that the extraction of potash can be profitably done only as a by-product where soda is made as the main product, otherwise it would not pay.

To save fuel, the spent water is therefore run in vats or ponds, exactly like those used for concentrating the lake-water and crystallizing soda, or for manufacturing crude sea-salt. In these vats, it is exposed in layers of a few inches to over one foot to the heat of the sun and the dryness of the air prevailing around the lake. There is a system of vats, arranged in such a way that the liquid after partial evaporation can be withdrawn from the crystallized salt crusts. This fractionizing or working in phases is very important, as, with changing temperatures and other conditions, the liquid may act again on the salt crusts and may even cause a loss of potash. The purpose of the evaporating and crystallizing process is to enrich the mother liquor with potash as much as possible, and to get out the other salts as free from potash as possible. Artificial heat is not necessary for this evaporation, and the only running expenses are a part of the wages paid to an employee attending to the vats in connection with the supervision with the soda-crystallization, and for pumping.

The first fraction of crystallization of the spent water

is an impure carbonate of soda and the liquor is allowed to remain on the soda crusts until cubes of sodium chloride first begin to crystallize out. There is no difficulty at all to note the end of this phase, and the liquor is then conducted to another vat. The remaining carbonate crusts can be recrystallized as they are comparatively pure, although hardly reaching a minimum of 96% Na_2CO_3 after grinding and heating. The solids of this liquid contain at this point about 6% and even more potash salts, and the liquid spindles about 35½ B.

Then the crystallization of sodium chloride sets in and thick crusts of this salt, very often in big beautiful cubic crystals, are formed on the bottom. This salt, of course, contains some carbonate and a little borate of soda, which, however, can be easily removed, if it is desired to purify the salt. When the salt precipitations, as far as the conclusion of this phase, cease, the appearance of the vat becomes different. The liquid must be drawn off again, as soon as fine silky crystallizations, consisting of carbonate, sulphate, and some borate begin to float on the surface.

In colder weather more sulphate is precipitated than in warm; as a rule, it might be said that this salt mixture contains between 60 and 70% of sodium carbonate on a dry basis. Sometimes small precipitations of sodium chloride occur and the Beaumé hydrometer indicates the changing specific gravity of the brine during this evaporation. As a rule, the highest density is 39-39½ B., and then the liquid becomes lighter, sometimes suddenly several degrees, then heavier again, however keeping under the high mark. To follow the varying degrees of aggregation of ionic dissociation in this solution, and the varying degrees of ionic concentration in the brine, indicated by the varying composition of the separating salts, is very interesting. Sudden precipitations from over-saturated solutions make this process theoretically rather a complicated one. This might cause difficulties in separating the potash from other natural brines.

A chemical control, of course, is necessary to see that no potash precipitates. Under the conditions prevailing at Owen's lake, there is no danger of losing potash from the liquid by crystallizing out, until the solids of the liquid contain at least 40% potash salts, when the process is conducted with skill.

The solution that contains sulphuric, carbonic, some boric, chlorine, potassium, and sodium ions must then be evaporated to dryness in a separate vat. The salt crusts thus obtained are now completely dried out by artificial heat and then ground. Of course, by more complicated processes the potash salts can be purified further.

The whitish potash manure salt represents a mixture of the carbonates, sulphates, and chlorides of potash and soda in varying proportions; it is free from the chloride and the sulphate of magnesium, an important advantage against some of the Stassfurt products.

When employed by the Inyo Development Co. as their consulting chemical engineer, I, having had a long experience in the Stassfurt (Germany) potash mines and factories, as well as an agricultural chemist, suggested taking up the manufacturing of potash manure salts. Despite many failures of other concerns to create a potash industry in the United States, A. B. Davis, general manager of the Inyo Development Co., took up my proposition, and he deserves the credit of promoting the first manufactory of potash salts in American from natural brines. An experimental plant was erected this year, the results being entirely satisfactory. The first run produced potash salts running 20.41% potassium chloride, the second run 29.40%, and the third run 34.05%. These runs were made late in the season after the weather began to get cool; if they had been made when it was warm, the results would have been much higher. This experimental plant will now be extended, and the making of this American potash, on a commercial basis, will take place on a larger scale. Possibly the manufacture of purer potash salts will follow later.

Small Machinery

The Editor:

Sir—I think the articles in your issue of October 23 last, on the 'Psychology of Advertising,' are timely, and your stress upon the importance of the buyer's side is much to the point.

It is nearly 40 years since I entered a copper smelter to hold a very junior position, and nearly 30 years since I took a hand in the management of a mine, and all that time I have been reading advertisements and, directly or indirectly, purchasing mine supplies; so I have had a little experience. What I have found is that advertisers do not advertise what I want, which is something fitted for a small mine.

The bulk of the examples illustrated and described are the latest and largest of their kind. One would think, from reading advertisements, that no mine exists whose output is less than 1000 tons per week. The big winding-engine to hoist from 5000 ft., the big crusher to put through 250 tons per hour, and the big locomotives are very interesting to hear about and to see, but there are not many men who are likely to want them.

It is the same when one writes for quotations: ten to one, the replies are all for huge machines, and when one asks for something smaller, the curt reply makes one feel a very small potato indeed.

Some time ago I had occasion to investigate two new technical processes, and asked for estimates, etc. One made no reply—evidently we were beneath notice—the other sent an estimate for an output of 20,000 tons per month.

Now, putting America aside (where, I presume, there is nothing small even among mines) our country, Australia, is a big place, with famous and widespread mineral deposits, but how many mines are working whose

output is a regular 1000 tons per week? I venture to say, very few; and yet there are hundreds of mines needing machinery and supplies.

The average man is still somewhere about 5 ft. 8 in. in height, and about 140 lb. in weight, and the present War shows he is still the main factor, and not the 16-in. howitzer with its 20-mile range, and surely the day of the small mine is not gone? If it has, as our advertisements would lead us to think, then we have far too many colleges of mines, institutes of engineers, and technical journals, especially the latter.

But I venture to predict that the small miner is still worth the machinery-maker's courtesy and attention. Instead of always putting the big machines in the front, I would suggest that the small machines be the regular exhibit, and that the big fellows be used only for an occasional show, as the pride of the factory.

EDGAR HALL.

Silverspur, Queensland, December 14, 1915.

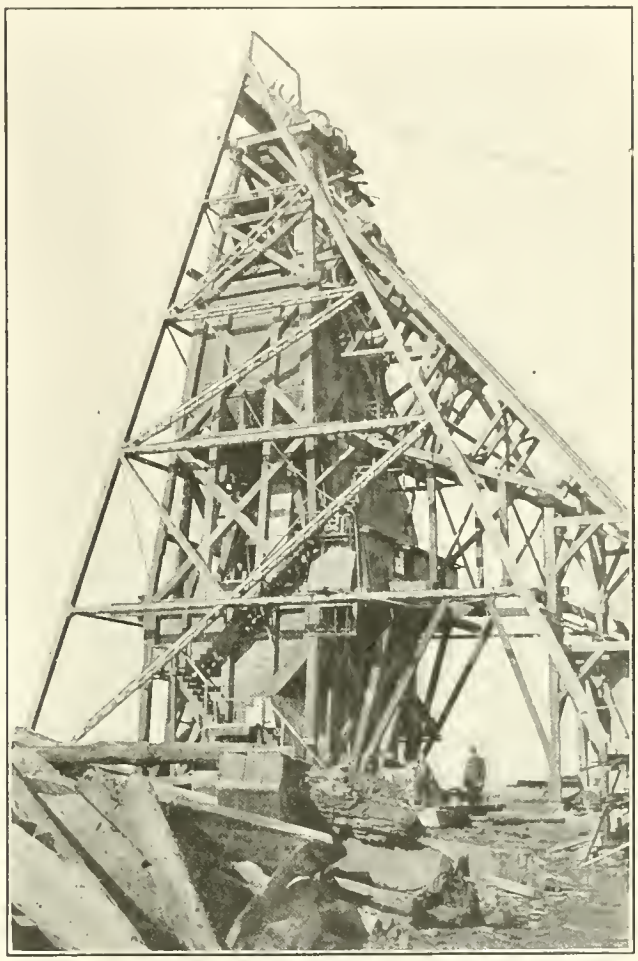
[We like to have opinions such as this, from buyers of mine supplies. As to the criticism that America has time only for big things, we are pleased to state that this megalomaniac tendency is fast decreasing, and our business firms are rapidly recognizing the desirability of courteous treatment for all customers. The small buyer of today may be the big buyer of tomorrow; furthermore, the small man talks more than the big buyer, and is at once a strong friend of the firm that treats him well and a vindictive disparager of the company that is inclined to be contemptuous of an order for a couple of rock-drills or a half-dozen cases of dynamite. Large mining companies, accustomed to being pointed to as typifying standard practice, are apt to buy machinery at cut-throat prices, because so many dealers are anxious to have their name-plate at the big plant. Generally speaking, a dozen orders at $1000 each from small operators will bring more profit than a $15,000 order from a large company.—EDITOR.]

An Unusual Head-Frame

The Editor:

Sir—Relative to P. B. McDonald's article on head-frames in your issue of December 25, the enclosed photograph of a head-frame that I erected for the Fremont gold mine in Amador county, may be of interest.

It is seen that the shaft is an incline and that the cable, as it leaves the sheave, goes to a hoisting-engine situated on the hanging wall. As a matter of fact the hoist is on a hill at a relatively high elevation above the collar of the shaft. The resultant of the pull on the sheave, being between the two lines indicated, lies at a difficult angle to counteract. The pull tends to tip the head-frame over. As it was impossible to provide against this pull by the back-brace, on account of the flat angle of the resultant, I resorted to the expedient, now not uncommon in the building of high head-frames, of anchoring the front legs securely to heavy concrete foundations. The front legs of the structure, that is the two legs on the foot-wall, are in tension when hoisting takes place. The head-frame is of the so-called A type, and all four legs are battered. It is entirely of steel, although the central structure containing the ore-bin, waste-bin, and crushing plant, is of wood. However this wooden tower is



THE FREMONT HEAD-FRAME.

entirely separate from the head-frame, so that vibration or settlement of the structure does not affect the steel. The head-frame was designed on the basis of being able to withstand a load equal to the breaking strength of 1¼-inch plow-steel cable; it is 92 ft. high from the collar of the shaft to the centre of the sheave.

J. R. CAHILL.

San Francisco, January 13.

Another, and Earlier, Ball-Mill

The Editor:

Sir—As a further contribution to your "ancient history" communications relating to the genesis of the more modern forms of machinery for ore reduction, I beg to submit the following:

In 1863 I designed and superintended the erection of a mill at Black Hawk, Gilpin county, Colorado, for the treatment of gold-bearing sulphide ores of that region by pulverizing and roasting, followed by amalgamation.

The ores were broken by a Blake crusher, and then

ted to a Howell mill, named after its patentee. Briefly described, it was a strongly built fan-blower, with steel shod arms to the rotor. It had heavy removable corrugated cast-iron rim within the casing of the machine, to receive the impact of the ore thrown against it by the rotor. This mill received the ore from the Blake crusher at the open centre, corresponding to the inlet of a fan blower. The rapidly moving rotor-arms beat the ore back and forth within the casing; and as it became sufficiently fine it was carried from the mill by the air current caused by the rotor, as would be the case with a fan-blower, with this exception: the rotor moved the reverse way from that of a fan.

This was, as far as I now know, the first of the type of 'hammer' or 'beater' mills, now in some considerable use in dry pulverization of minerals softer than the general run of ores.

While the rapidly revolving steel-shod arms pulverized the ore satisfactorily as to size, quantity, and power, the wear and tear and delays due to replacement of worn parts made their operation too expensive.

So, in 1865, I set my wits to work to devise something better. I had heard of a drum, containing iron balls, which was charged with a batch of ore and run until the ore was sufficiently fine; and then it was emptied and charged again. Whether this was the Lundgren pulverizer, described by J. Ross Browne in 1868, I do not know; the name having passed from my memory.

I liked the principle of the machine, but not its application to requirements. I needed something to work continuously, not intermittently. Remember that Black Hawk was then over 600 miles from any railroad, and that all freight was mule or ox-drawn. But the foundry and machine-shop of Langford & Marshall, at Black Hawk, had scrap-iron from poorly designed and unnecessary machinery, bought and sometimes erected to treat supposititious ores from 10-ft. shafts of so-called mines. Those were times that tried the miner's soul. Failures were constantly calling for other devices to be substituted as makeshifts. Something had to be done. The mill was idle because the last 'Howell' had finished its windy howl and beaten itself to dissolution. But the remains were sold for scrap—from which to make other things.

With the active co-operation of John W. Nesmith, then the superintendent of the Langford & Marshall foundry, and afterward president of the Colorado Iron Works, of Denver, the ball-mill was constructed as follows: Two circular cast-iron dises, four feet in diameter, for the heads, were mounted, three feet apart, on a steel shaft. For staves for this drum, or barrel, wrought-iron bars $\frac{1}{2}$ by $2\frac{1}{2}$ inches were used. Each bar was spread by forging at the ends and in the middle, for the length of an inch, to measure at those points $2\frac{5}{8}$ inches. They were then bound on the heads and at the middle by three hoops of iron. Thus there were openings of $\frac{1}{8}$ inch between the staves.

One end had a circular opening around the shaft through which the ore could be fed. The other head was closed; but each head had a hand-hole with a suitable cover, which could be removed at will, to give access to the interior of the drum. The drum was mounted in suitable bearings for the shaft, and on a wooden frame, provided with a wooden casing to confine dust. A gear wheel on the drum-shaft, and pinion mounted on a counter-shaft with a pulley, furnished means to drive the drum at the speed of about 21 r.p.m.

When this installation was completed, about 1000 lb. of chilled cast-iron balls was put into the drum, and the trial began. The ore so ground flowed from the mill through the spaces between the staves. From the bottom of the casing, which was hopper-shaped, a screw conveyor moved the crushed and ground ore to a revolving screen of 30-mesh wire-cloth. That which passed through the screen went to the roasting-furnace, and the coarse material flowed back with the feed to the drum.

This device apparently worked perfectly from the start, to the extent of grinding one ton per hour for a few days. Then we observed that its hourly output decreased day by day until but one-quarter of a ton hourly was all we could produce. Examination showed that the staves had been worn until they were so smooth that they slipped under the charge of ore and balls, instead of being lifted so as to cause the balls to fall to impact the ore.

We overcame this defect by removing some of the flat staves, and placing about 12 of them at regular intervals between the other staves at right angles thereto; so they projected from the inner sides of the staves radially toward the shaft. These formed barriers to prevent sliding of the drum under the load; and, further, to lift the balls and ore to a height that they might beat upon each other as they moved downward on the ascending part of staves. The mill then was more efficient than at the start.

But another trouble arose: The chilled cast-iron balls proved too brittle for the work, and broke rapidly. After trying cast-steel balls, wrought-iron balls forged from old shafting by hand and sledge-hammers, and swages, proved successful; and wore to 1-in. diameter, keeping their spherical form up to the periodical times for their removal from the drum. These small balls were mixed with pebbles of flinty quartz and used in a lengthy rotating cylinder to pulverize the roasted ore. But that is another story.

N. S. Keith.

Philadelphia, December 21, 1915.

Costa Rica has an area of 23,000 square miles, which is a little less than that of West Virginia. The population is 411,000, of which 55,200 are in San Jose, the capital. The total debt of the country is $17,000,000, of which nearly half is held by English interests and the remainder mostly French. Money-order and parcel-post service exist; the custom regulations give facilities to imports; foreign patents and trade-marks are well protected.

Research Problems

By Will H. Coghill

INTRODUCTORY. How often we hear a mining engineer remark that he has certain theories about certain phases of some particular branch of his profession and that some time he will investigate. Time passes and the theories are never tested, while so many young men in the mining schools are wondering where they will get the problems for their thesis.[1]

If all unfinished problems were made public some one might find something among them that would make a special appeal and by a further investigation be able to produce results that would be a contribution to science, if not of commercial value. It is with this in mind that I submit the following 'near processes.'

WET DESULPHURIZATION AND FLOTATION. To my knowledge, outside the work of the Nipissing, very little has been written regarding wet desulphurization.

About the effectiveness of the nascent hydrogen liberated by the caustic soda and aluminum in decomposing silver minerals there is no question. But other minerals are included in the category. And here is where the process may be baulked entirely. It is very likely that in making the maiden attempts with wet desulphurization at the Nipissing they happened to hit upon the most fortunate sample possible. I tried it on an oil-flotation tailing. After 10 minutes of agitation the sheets of aluminum were covered with a nasty black paste. The natural inference was that this was caused by the oil that had remained in the tailing. In order to force the test to completion aluminum impellers were used on vertical revolving shafts for agitators. The same deposit formed. Coarse sand was then placed in the bottom of the containers to act as a scouring agent, and, after considerable effort, the test was put through, and it was found that the silver, which was otherwise refractory to cyanide, dissolved readily after desulphurization. The black deposit was then collected and tested. No trace of oil could be found, but a large percentage of lead in its stead. As some sulphur was also present, the first impression was that it was a sulphide or sub-sulphide of lead. Galena was present in the tailing but if native PbS were converted into artificial PbS in one step it meant a new bit of chemistry. That was hardly probable. After a lapse of several months wet desulphurization was again tried; this time on a slightly oxidized lead-zinc ore. The same black mess appeared in large quantities. This ore had not yielded its lead freely to oil-flotation.

About this time I had a stock of galena on hand that had been given a sulphate coating by roasting. Directed by something other than scientific reasoning, I put some of this into a caustic soda solution with sheet aluminum. A thick deposit formed on the aluminum and the solution was soon clouded with a dark-brown colloidal substance. The dilemma had passed. Of course $PbSO_4$ is decomposed, forming Pb, H_2O, Na_2S. This was corroborated at once by pure $PbSO_4$ giving a mass of spongy lead. The sulphated galena had not floated easily by oil-flotation, but after brightening it by wet desulphurization it floated freely.

Cerussite ($PbCO_3$) is readily decomposed by this process and spongy lead is deposited on the foil (these tests can best be made in test-tube). I think anglesite ($PbSO_4$) acts in the same way, though I could not get a good specimen to test. My impression is that by this method one can detect the slightest amount of oxidation of galena (fresh galena is not decomposed), and that if in flotation work, galena is escaping, the tailing should be panned and the galena tested for a sulphate coating. I used galena that was very slightly oxidized by dilute sulphuric acid, and got a distinct reaction. Aside from being an aid in determining the character of an ore it is not impossible that some day wet desulphurization might be worked into the flow-sheet of a flotation plant. The Nipissing[2] charges off 0.54c. per ton to desulphurization and gives a 12-hour treatment. Oxidized galena could probably be brightened in two hours with the same strength of solution if the deposit of lead on the aluminum did not prove to be a nuisance. I thought at one time that I had a method worked out that would prevent the deposition of sponge lead on the aluminum, but have never concluded the experiments.

[1] Possibly the fourth-year man in the mining school should not do a thesis. For my part I would like to see the thesis thrown out of the curriculum of the fourth year. The ideal research problem is the one that the investigator has met 'face to face' on his own initiative, and it is only under such circumstances that he gets the proper inspiration for original thinkiug. The parent spends about $500 for the son's fourth year in school only to have him thrown on his own resources, when, in fact, he has none and cannot be expected to have, and he flounders around for weeks to do work that should be done in a few days; and in the end he is deceived into thinking that he is qualified to go out and take a 'position' when in fact he should have only a 'job.' On the job he will have plenty of opportunity to develop initiative, and it will be more likely to develop if the instructor will take the thesis period and give him careful instruction on the 'known' instead of pushing him out into the 'unknown.' So often we hear that the prescribed course has not room for this and that. If the thesis period were eliminated there would be more time. Of course, the man learns something while on his thesis, but I believe he would learn more in school and be better prepared to step from a 'job' to a 'position' if the instructor gave him more of his time in the fourth year.

[2] J. J. Denny, MINING AND SCIENTIFIC PRESS, Sept. 27, 1913, Page 488.

Hyposulphiting. I picked up the statement in one of the old volumes of the transactions of the A. I. M. E. that freshly precipitated silver sulphide dissolves instantly in the Russell extra solution ($XCuS_2O_3 \cdot YNa_2S_2O_3$). This seemed to suggest a way out on an ore that had proved refractory toward cyanide on account of the copper and silver being chemically combined. Knowing that wet desulphurization would decompose the copper-silver mineral, throwing down cement silver, and being aware also of the avidity with which sodium sulphide attacks silver, making silver sulphide, it seemed quite possible then to dissolve this freshly formed Ag_2S in extra solution upon a few minutes agitation. Fully aware that the extra solution is awkward to handle as compared with a cyanide solution, the idea of a nearly instantaneous dissolution of the silver, where the copper could not interfere, seemed attractive.

A specimen of pyrargyrite was therefore selected, crushed through 200-mesh, and mixed with sand to make an ore assaying 24 oz. silver. It was given the wet desulphurization treatment, washed, and then an hour's agitation in a closed jar with a 1% solution of Na_2S. After washing, it was agitated in the same manner with a 1% extra solution. The periods of agitation in hyposulphite varied from five minutes to two hours, and the percentage extracted varied from 25 to 40; the five-minute treatment in some cases being as effective as any. The probabilities are that all of the Ag_2S that was formed did dissolve instantly according to the original premise, but that it existed only as a coating on the particles of cement silver, and as soon as the coating was dissolved the dissolution ceased. Or, on the other hand, it is possible that the copper which replaced the silver when the silver went into solution formed an impervious coating on the sulphidized silver. If the latter portion of the silver had proved as soluble as the former the dissolution of the silver would have been as simple as the old style trough-lixiviation, but, under the circumstances, the scheme had to be shelved.

Carbon in Cyanide Solution. I read with a great deal of interest the articles of Messrs. Feldtmann and Ralston[3] on the precipitating power of charcoal and graphite in cyanide solutions. They concurred in the opinion that "an explanation of how and why the gold is precipitated by charcoal will throw light on the action of graphitic schist," and that "the gold-bearing ions are doubtless adsorbed in the charcoal;" and also that it was pretty thoroughly demonstrated that gold entered "the pores of the charcoal." Whether a solution enters capillary tubes or cleavage-planes or planes of fracture caused by crushing, the phenomenon is plainly one of capillary action (capillary action can be demonstrated as well by two plain plates of glass set close together, as by a capillary tube).

Now, the capillary rise in a tube is merely one of the manifestations of the forces acting in the surface of a liquid and known as 'surface tension.' We can therefore attribute the penetration of the pores of the charcoal to surface tension. If the pores are penetrated by a solution containing gold-bearing ions, and if by reason of some chemical reaction (the writers discussed the reactions) these ions cease to exist as such, others would follow at once, as the consequence of diffusion. So I reasoned that in order to check precipitation of gold by charcoal one would have to reduce the surface tension of the solution. Amyl alcohol was chosen as the auxiliary reagent on account of its phenomenal effect in this regard. I duplicated Feldtmann's experiments as nearly as possible, using 200 cc. of solution, titrating 2 lb. KCN, 0.5 lb. CaO and assaying 9.63 mg. gold per 100 cc. The charcoal was crushed to 10-mesh and 10 gm. was used in each test. For the first trial two tests were allowed to stand for 24 hours side by side, one with and one without amyl alcohol. The alcohol was added to make a 2.4% solution, which, disregarding the effect of cyanide and lime, would reduce the surface tension of the solution from 71 to 26.[4] The amount of gold precipitated per 100 cc. was 9.23 and 7.88 mg. in the non-alcoholic and alcoholic solutions, respectively. The difference was not great, but sufficient to give encouragment. From the amount precipitated, it seemed that the tests had stood too long, and since beakers were used which probably allowed a great evaporation of the alcohol, the tests were repeated in closed flasks and allowed to stand only 14 hours. Gold was precipitated to the extent of 8.91 and 5.56 mg. or 93 and 58%, respectively. The approximate surface tensions in the same order were 71 and 26. (I took the precaution to compare the dissolving rates of the alcoholic and non-alcoholic solutions on gold foil and found that there was no difference).

The results make me feel that my theory—that the precipitation of gold on carbon can be controlled by the control of the surface tension of the solution—was correct, though I realize fully that I have not presented enough evidence to claim a proof.

Probably the largest repair job by means of oxy-acetylene was recently made at Chicago by the Oxweld Acetylene Co., when a gyratory-crusher spider weighing 40 tons was mended. A piece weighing 10 tons broke off, and a new spider would have cost $2300. The break was chipped out and 900 lb. of new metal had to be welded in. This work occupied two men per shift for 60 hours continuously. The hub was kept warm in a fire during this period to take care of expansion and contraction. After the job was finished the repaired spider was covered with sheet asbestos and allowed to cool gradually. Much expense and time was saved by this weld.—*The Excavating Engineer.*

Oregon has an area of 96,030 square miles, which is over twice that of Pennsylvania. Its population is 800,000, having doubled since 1900. Baker county produced $1,500,000 in gold in 1915.

Mining in Ecuador

By J. W. Mercer

*INTRODUCTION. It is difficult to write on this subject when there is, in all of the Republic, but one mining enterprise in actual operation, namely, the gold mines of Zaruma in the southernmost province.

It has been said that Ecuador is poor in minerals. True, it is almost undeveloped and not at all known, but there are many evidences of mineral wealth. How can a country be explored and developed without roads, to say nothing of railroads? Senators from the extreme eastern provinces, wishing to attend the session of Congress at Quito, instead of ascending the rivers and crossing the mountains, deem it preferable to take steamer down the Amazon to the Atlantic ocean, travel by steamship to Buenos Aires, thence across country and high mountains to Valparaiso, up the Pacific to Guayaquil, and thence by rail to the capital.

THE COUNTRY. Ecuador extends north and south along the Pacific more than 300 miles, and eastward about 500 miles across the Andes to the tributaries of the Amazon, an area of 116,000 square miles. The population is estimated at 1,500,000, but there has been no census. In the larger cities and the coastal region a mixed race predominates, the Spanish-Indian, but in the inter-mountain region the population is almost entirely native Indian. Of course, there are many direct descendants from the Spanish, and also foreigners from other countries.

The seaports are Guayaquil, Bahia de Caraquez, Manta, Esmeraldas, and Puerto Bolivar, in order of importance. Guayaquil, situated 830 miles south from Panama, on the west bank of the Guayas, 35 miles north from the Pacific ocean, claims a population of 75,000. Quito, the capital, in the mountains, 300 miles northeast from Guayaquil, has about 60,000 people.

Ecuador is served by three steamship lines running between Valparaiso and Panama, one of which conducts a coasting service between Guayaquil and Panama. River-steamers ply on all the large rivers, connecting the small towns and plantations with Guayaquil. The Panama Canal puts Guayaquil within eight days of New York.

The Guayaquil and Quito narrow-gauge railway (a New Jersey corporation) is the only railroad of any extent being operated. A number of other railway projects are under consideration, and some under construction. The greater part of Ecuador is inaccessible and undeveloped, because it lacks not only railroads but wagon-roads.

Tributary to the coast and extending 50 miles inland from the ocean to the foothills lies the richest part of the country. The river Guayas, flowing from the north through the bottom-lands, empties into the large bay of Guayaquil and furnishes convenient transportation. These river-lands are rich and can grow all tropical products. Ecuador's great wealth is in *cacao* (chocolate); the total weight of this material harvested in 1914 was approximately 100,000,000 pounds. The lowlands produce many other articles of commerce, but next in value is the *tagua* (ivory-nut) and the *toquilla* (panama-hat fibre). Ecuador also produces coffee, rubber, sugar, tobacco, rice, coco-nuts, bananas, oranges, and pine-apples. Aside from the coastal lowlands the country is mountainous and little developed, yet the many fertile valleys yield all the temperate-zone cereals, vegetables, and meats; excellent potatoes, wheat, rye, barley, beans, peas, alfalfa, cattle, sheep, and hogs. Altitude compensates in climate for what the country lacks in latitude.

The timber of Ecuador is not well known. It is claimed that there are many varieties of useful hardwoods within the coastal lands, but in the interior it is scarce. The gold mines at Zaruma obtain many varieties of soft woods, including cedar, cinnamon, etc., but they do not endure long. Hardwoods are scarce and far away. The soft woods may endure if kept from the air, but if subjected to air and moisture, they decay rapidly. Mine-timbers last only from one to two years. Boring insects play havoc in the wood-work of buildings. The timber from the coast cannot be used owing to lack of transportation.

In the matter of industries there is little to say. Every large city has a brewery and there are a number of small businesses in various places, such as flour and cotton mills; the manufacture of panama-hats is an extensive industry, it being done by hand; also there are a number of important sugar-mills.

GEOLOGY AND MINERALS. The immense uplift of the Andes throughout the entire length of Ecuador has furnished a vast area for the prospector, but for many reasons the country is difficult of access. Lack of roads and railroads leaves the inter-mountain region remote and inaccessible, and the fact that the north-central part is covered with volcanic ash and that a large area in the south and east is covered by a dense growth of trees and jungle makes it almost impossible of exploration. The vicinity of Mt. Cotopaxi offers an interesting exhibit of various periods of eruption. In many places where the soil has been deeply cut by rivers and railway-grades there are several layers of volcanic ash alternating with layers of black loam. In places the ash is 6 ft. and the black loam 3 ft. deep. It is noticeable that the thickest

*Contributed by the author. A paper also read before the Pan-American Scientific Congress, Washington, December 1915.

beds of ash are opposite the volcano, while 25 miles away the layers thin to a few inches and are much finer in texture. In the tropical and semi tropical reaches of the mountains, the rapid oxidation, disintegration, and erosion, followed by dense floral growth, have so changed the face of the earth that it is impossible to know what lies beneath. Even in the vicinity of ancient mine workings it is seldom possible to find the bottoms of the excavations exposed.

I believe there has not been any geological study since that of Dr. Teodoro Wolf, therefore little can be said about the mineral possibilities of Ecuador. Iron ore in workable quantity has not been discovered, neither have any important deposits of lead, zinc, or copper, although the latter is known to exist in several places.

Oil is now being found in the lands along the coast west from Guayaquil, in the district called Santa Elena. It was discovered by the earliest voyagers, and Dr. Wolf in 1892, made a report on it to the Government. Since then a small extraction has been made from the superficial capping. In 1912, an exploratory bore reached a depth of 2000 ft. with negative results except in the superficial area. In 1913 the production was at the rate of 10,000 to 20,000 bbl. for the year, being used locally as fuel for furnishing power. There are two grades reported by recent analyses: (*a*) Green oil, 24-28° B. (*b*) Black oil, 18-19 B at 60° F. Both are low in asphaltum, gasoline, and kerosene, and high in fuel and lubricating stock.

Coal exists in various places, a low-grade lignite, high in ash and volatile matter. In the provinces of Azuay and Loja some wide seams have been discovered, but as yet they have not been tested adequately.

Mercury has been discovered in the province of Azuay. Silver was mined by the ancients and particularly in the district of Pillsum, province of Cañar. In 1891-'94 an attempt was made to explore these mines, and some ore was shipped to foreign markets, but they were abandoned, probably for lack of capital and means of communication.

Gold is the only metal being produced in any quantity. I am unable to procure close figures as to the amount produced from the small placer work of the Indians, but I am supplied with the figures for the vein mining, and I believe we may estimate the total annual production at $600,000.

Gold probably exists in all the rivers on both sides of the mountains. The Indians wash the gravels in many places and bring it in small quantities, to be sold to the merchants and banks. Particularly do they come from the mountain tributaries of the big rivers on the east side of the main watershed. I believe the Napo river and its tributaries at present contribute a small amount and that not far from the city of Cuenca, in the district known as Sigsig, the Indians wash out coarse gold and sell it in the large towns, but it is said that the whites are not permitted to enter that district. Again, in the extreme south-east some small amount of gravel- washing is done. Also near the north-west coast in the province of Esmeraldas a United States corporation conducted some placer development about ten years ago, but this work was discontinued; it was said that the gold could not be recovered. Platinum has been reported in the gravels of some of the rivers in the north west. In the province of El Oro, in the district of Zaruma, the river-gravels contain small quantities of gold, but it is usually flaky and light and the gravel extremely shallow.

Tradition has it that in many parts of this country, the veins contain gold in fabulously rich pockets. This has been assumed because of the vast quantities of plate, images, and ornaments of gold found in the possession of the natives by the Spanish conquerors. However, it is not likely that there existed great treasure-houses where the gold could be chiseled out in chunks, but it probably came from a long period of small gains. The Spaniards operated haciendas and employed their slaves, when not engaged in agriculture, in working the mines, and also no doubt there were many independent natives washing the ores and gravels for small returns. The vast quantity of gold possessed by the natives at the time of the Conquest, used as plate and for ornaments and temple decorations, probably came from small accumulations over centuries.

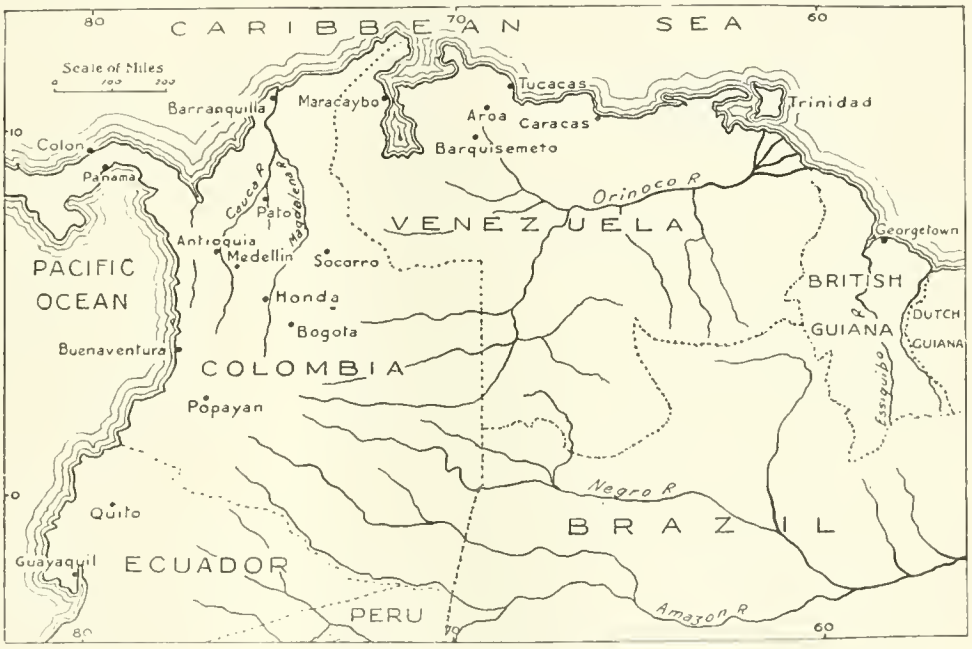
Gold-bearing quartz veins exist in the mountains in many parts of Ecuador, but the only ones now being developed are those in the district of Zaruma in the province of El Oro. History tells us that soon after the Conquest the Spaniards discovered the natives working important gold mines, and founded several towns because of the mines. The principal ones were Zaruma, in the south in the province of El Oro; Zamora, in the south-east in the province of Loja; Sevilla del Oro and Logroña del Oro, both in the central part of the Republic.

After the Spaniards founded the towns of Zamora and Sevilla del Oro, the native Indians joined together in great numbers, overpowered and massacred all the foreigners except the women and children, whom they carried away into captivity. In various histories it is stated that the Spanish governors were exacting exorbitant taxes, requiring the Indians to bring in large quantities of their gold, presumably to be sent to the Spanish Crown; after this had gone to a point where they would not longer endure it, the Indians organized and swept in one night upon the sleeping Spaniards. One account is that to punish the Spanish Governor-General they killed him by pouring molten gold down his throat, stating that they hoped he would be satisfied.

We often hear of discoveries in the eastern provinces among the big rivers that help to form the Amazon, but that entire region east of the Andes is without adequate roads. A north American prospector recently reported the discovery of a large quartz vein which he estimated would assay 1 oz. in gold per ton. This was on the lower Napo river, and in order to reach Quito he had traveled three weeks, mostly afoot.

Mining. The mining laws of Ecuador are fairly liberal. A pertenencia or lode mining-claim is 200 by 600

metres, containing twelve hectares, or thirty acres. It is acquired by location and held by the payment, in advance, of an annual tax. This is equal to $5 in United States money for claims not in exploitation, and $25 for claims in exploitation. If the possessor should fail to pay his taxes during the month of January he may still redeem the property by paying a double tax the month following. If he should cease to pay taxes for any length of time, the property becomes subject to auction-sale for the benefit of the Government, at which time the original owner is allowed the first opportunity to buy in, by paying the back taxes and the penalty. Mining machinery and supplies are admitted into the country free of duty. Likewise the product of the mines is not charged any export duty. There are no smelting works or mints, and at present Ecuador has no means for the purchase and coinage of gold bullion.



MAP OF PART OF SOUTH AMERICA.

Gold Mining at Zaruma. This district is in the extreme south in the province of El Oro, 150 miles from Guayaquil. The latitude is 3°45′ south, the longitude 82° west, the altitude from 2000 to 5000 ft. above sea-level. It is reached by steamer to Santa Rosa, thence by mule-back for 45 miles.

It was just before the middle of the 16th century when Francisco Pizarro and his associates went by boats from Panama to Ecuador. After discovering the Gulf of Guayaquil, and conquering some 50,000 Indians on the island of Puná (now with a population of only 100), the first headquarters was made at a point where now is situated the town of Tumbez, at the mouth of the river of the same name, near the boundary between Ecuador and Peru. This river empties into the gulf near its southern end, its source being 125 miles east. Amid these rivers and hills lies the mineral district of Zaruma. During the first years after the Conquest the adventurous Spaniard ascended the river in search of the origin of the gold found in the gravels, until, arriving at the heart of the Zaruma district, he found native Indians engaged in washing gold from the outcrops of large quartz veins. Here, in 1549-'50, he founded the town of Zaruma, the present seat of the canton, now a village of 800. The famous road built under the rule of the Inca passes not far from Zaruma, and here may still be seen stretches of the original stone pavement. Here they began mining for gold, and subsequently explored and worked veins over a large area not now defined in extent, but at least 15 miles long north and south by 5 miles wide. One may still see the marks of caves denoting a vast number of old workings, now filled with water or covered with a tropical growth. Entrance and exit were by shaft, adit, and incline, and the ore was carried out on men's backs. They probably took out the rich streak and left standing the low-grade quartz, filling back under-foot the broken waste, occasionally leaving a pillar of vein-matter. Seldom is high-grade ore found standing, and it is impossible to sample the bottom of the workings because of the accumulation of filling and mud. Work evidently ceased at the water-level, where oxidation ended. The bottom of the oxidized zone is usually 100 ft. beneath the surface, but the greatest of the ancient mines undoubtedly reached a depth of 300 ft. The only tools of metal ever found are some soft-iron bars. The ore was treated by grinding and washing. A vast system of ditches and reservoirs spread over the district and many a large outcrop shows signs of washing. Hundreds of stone shoes and dies of the little two-stamp mills have been found in the soil, and there are also visible the beds of old arrastras. The stamp-mill consisted of two stamps; the mortar was a wooden box of the size of the modern candle-box; the die an oval boulder having on its upper side two cupped-out wells, into which dropped the stone shoes, smaller boulders with the upper end sharpened to a neck. This neck was driven into a wooden boss-head, tapered to form a stem on which was a wooden spike to serve as tappet. The cam was operated by an overshot water-wheel. The principle is that employed today in our gravity stamps, with steel replacing the stone. After stamping they probably panned the free gold.

In 1815 Spain sent an agent to Ecuador, who reported that many mines were being worked, but after the War of Independence it almost ceased for a long time. In 1876 Dr. Wolf made a study of the district and published a short description in 1879. In 1878 mining men came from Chile and Peru to make the first denouncements (locations), and in 1880 the Great Zaruma Gold

Mining Company was organized in London. Two years were spent in road construction and attempts to introduce large machinery, but not having finished the road, and the machinery being too heavy for mule-back, it has lain abandoned at tide-water ever since. In 1883 the English company's manager joined the Salazar revolution and was killed at the gates of Quito. Between 1884 and 1887 the English company raised additional capital, worked the mines, and made some shipments of gold. In 1887 it was liquidated and a new corporation, calling itself the Zaruma Gold Mining Company, was organized to continue development. In 1889 French capital investigated the district, but discontinued work the following year. In 1895 the English company abandoned the district entirely, their failure being due probably to lack of improved metallurgical methods and adequate means of communication with the coast. In 1897 a company organized in the United States, took over the properties and is still operating.

The geological structure of the district has not been accurately determined, but it consists mainly of large flows of andesite, dacite, rhyolite (some porphyritic and some brecciated), lying on the mica-schist that appear at the south end. This area has been extensively faulted and intersected by veins of quartz and calcite, all of which probably contain some gold. In the country-rock a few pyrite crystals are found, while near the veins this mineral is more plentiful, and within the veins there is often a heavy mineralization by pyrite, chalcopyrite, blende, and galena. The quartz veins often reach a thickness of more than 15 ft. and in some places many large veins lie parallel, forming a great mountain of quartz and country-rock, with here and there ancient workings. On the surface the country-rock decomposes rapidly, resulting in yellow and red clay. Ridges often indicate quartz and many of the canyons are worn deep by decomposition and water. The area described is literally peppered with ancient workings and in most places where recent development has penetrated beneath ancient mines, workable ore has been found.

As already explained, the country is andesitic and is cut by several large north and south faults and numerous cross-faults. One large fault passes through the centre of the district, having a course a few degrees west of north and dipping 70° east. It may be traced for several miles with ancient mine-workings along it. This fault frequently makes orebodies composed of quartz and calcite. Coming into, but not found to cross it, are large quartz veins with a strike north-east by south-west and a dip to the east of 70° or steeper. Large orebodies make at the junctions. Numerous cross-faultings occur, causing a slight offset in the veins. The walls of the main fault are often loose, but those of the true veins are firm. Ore-shoots are irregular in the fault and regular in the veins. In character the veins are of quartz, sometimes containing mineralized country, and in the vicinity of the fault will also contain large quantities of calcite. The sulphide minerals, pyrite, chalcopyrite, blende, and galena, are also present. The entire vein-matter contains fine particles of free gold, so scattered and small as to be invisible to the eye, and it is probable that the gold is mechanically locked in the quartz and sulphide. Occasionally an exceedingly rich streak is found, made up of a black mineral, probably tetrahedrite, containing fine particles of free gold. The mines are opened by adits and shafts. Prospecting drifts usually follow the vein, but if the walls are loose, laterals are run. Several vein systems have been developed and partly mined, the shoots ranging in size from 3 to 15 ft. thick, and in gold per ton up to $30. In silver the ore averages $1 per ton. Of course, there have been developed besides many shoots too low grade to be worked by small scale operations. The ore, as milled is a mixture of quartz and calcite, containing sulphides to the amount of 10% of the total weight. Weekly development samples are taken from the various faces and after the ground has been opened, systematic sampling is completed. Several methods of stoping are employed. Where the walls are loose, close filling is done. In veins having firm walls, box-chutes are put in and the shrinkage system employed, while in some of the tight narrow veins the stopes are left open and in some cases pillars of vein-matter are left over the level run-way. Underground drilling is almost entirely by air, there being employed the one-man hammer-stoper, the jack-hammer for sinking, and both the mounted jack-hammer and the regular drifter for development.

By long experience in milling operations and numerous experiments, it has been determined that the metallurgical methods so far most satisfactory for the treatment of these ores is—after crushing—re-grinding in tube-mills, followed by agitation in cyanide solution. As there is neither smelter nor mint in Ecuador, all bullion must be shipped to foreign countries. The principal water-power installation is a 60-in. concrete tube, 2½ miles long, delivering 6000 cu. ft. of water per minute under a vertical head of 150 ft. The 40-stamp mill has an 8-ft. Pelton wheel on the line-shaft. In a like manner the crushers are direct-driven, while the hoisting-engine is operated by a 9-in. Francis-type turbine, reducing the speed through gears. From a low-head power another line drives three air-compressors by means of Pelton wheels, direct-connected. Concrete is employed for the tube instead of conducting the water in an open ditch, because of the fractured condition of the mountain and the certainty of land-slides.

The distance is 45 miles from tide-water. The trail is difficult of grade and during the rainy season almost impassable. All machinery and supplies must be sectionalized for transportation by small mules. Mule-freight ranges from a cent per pound in the time of good roads to 20 cents in time of bad roads.

The available workman is a mixture of Spanish and Indian, the type found in most of the towns and cities. The full-blood native in the higher altitudes lives by cultivation of the soil; he seldom comes to the low country and does not care to enter the mines. But in the few cases where they have become familiar with mining, they

prove exceptionally good workers. The native need not come to the mines because he can live on rice and bananas; as in all parts of the world where Nature drops the ripe fruit into the mouths of her beloved children, they seldom work. But these Ecuadorians usually show ability and eagerness to learn and become good workmen as miners, drilling both by hand and by machine. They also become good mechanics. Since there are no other mines in the Republic, they must learn here. The common laborer is considered unreliable, but those who do important work, such as mechanics, carpenters, drill-runners, timber-men, mill-helpers, and clerks, are steady, especially since they have obtained food free. The wages range from 50c. per day, in United States equivalent, for common labor, to $1 per day up for the miners, the latter based upon the depth of hole drilled; many miners make $3 per day? All labor receives free food. Over a long period the drilling speed has averaged two metres per shift per man for single-hand work and 14 metres per shift per man for the machine-stoper. There are at present employed 500 native Ecuadorians and 40 foreigners.

Because of extraordinary overhead expenses, such as traveling agencies, attorneys, hospitals, management, etc., with also excessive repairs and high transportation, costs must always be considerably higher than in similar operations in settled countries, and because of this it is all the more important in such an enterprise to attain to a large tonnage basis of operations, and that again calls for adequate transportation.

Isolation and lack of railroads cause difficulties unusual at similar operations in well-developed countries. The possibility of steamship delays and the bad condition of trails require that machinery and supplies be anticipated long in advance. Another hardship and expense, often causing delay and grief, is the necessity to sectionalize all machinery to a maximum load of 300 pounds. Of this necessity it is often difficult to convince the outside manufacturer. Foreign manufacturers desiring business with these republics should send representatives that know the language and customs, and then endeavor to grasp their point of view and requirements. All this will come in time, and with the other much-needed aid of banking and steamship connections there will build up a large interchange of commerce of great mutual advantage.

The Zaruma mining district ranges in elevation above sea-level from 2000 to 5000 ft. The climate is equable and agreeable. During the 17 years the thermometer has ranged from 51° to 93°F.; the averages for each day are with almost no variation, minimum 63°, maximum 83°, average 8 p.m. 70°. The rainy season begins in December and ends in April, the remaining seven months being without heavy rains. The average annual rainfall is 60 inches. It is always cool in the shade, and at night one needs at least one blanket throughout the year. During the rainy season brush and vines grow to the height of a man, but by the end of the dry season all is destroyed.

Rice is the staple cereal and is planted on the steep sides of the mountains, toward the end of the dry season. With machetes the natives cut all the dry brush and allow it some weeks in which to dry, after which it is burned; and then, with iron bars, holes are punched into the hard-baked clay soil and the rice grains dropped. When the heavy rains begin, it soon sprouts and by the beginning of the next dry season is harvested by clipping off the heads. Trees and garden vegetables grow rapidly during the rainy season, but slowly by irrigation in the dry season. Flour is imported from the outside, potatoes and all temperate-zone cereals are brought in from the higher altitudes. Coffee, bananas, oranges, pineapples, and *avocados* grow in the district. All classes of fowl flourish in the district, and sheep and goats may be brought in from the higher altitudes. Excellent beef may be had from the high altitudes to the east and southeast, but cattle do not thrive on the grasses of the lowland; therefore a number sufficient for two weeks is brought in, killed, dressed and hung in the refrigerator. Hogs are raised in the district.

Distilled or boiled water is provided at all times, as the river-water is dangerous during the first excessive rains, when all the world is being washed into spring and river. A medical staff is maintained and a constant fight conducted to prevent illness and to better the conditions of hygiene. The methods employed at Panama have been followed and an energetic fight instituted against malaria, the hook-worm, and other ills of the tropics; but yellow fever and bubonic plague have not been known. The surface is drained and kept clean; the brush is cut; rubbish and garbage are removed daily, and dwellings are provided with screened quarters and water-works. A community can be brought to a high state of sanitation by proper care and prevention, but it is difficult to secure the co-operation and assistance of the less intelligent native population.

The mining company has introduced several welfare improvements: it has voluntarily given free food to all the workmen, deeming that this makes for health, strength, and steadiness; the company provides schools free to all children in the district; it operates a boarding-house for feeding the staff and runs a garden where most of the temperate-zone vegetables and local fruits are grown for their benefit; large refrigerating rooms have been installed where meats may be hung and all cereals kept in full strength and free from insects; the company provides a building used as a miners' club, a club for the staff, and a chapel. The latest dwelling used by employees is made of concrete; floor, walls, and ceiling are all reinforced-concrete, the roof is of local tile, the windows and doors are screened. These are practically insect-proof and sluiceable, so that roaches and fleas cannot harbor therein. This type of building is permanent, whereas those first built of ordinary lumber rapidly decayed from boring insects and rot. The native village and all staff dwellings are equipped with water, bath and sewer. For diversion, baseball, tennis, swimming, riding, and dancing are popular.

Concentration of Tungsten Ore

In a paper before the Colorado Scientific Society the practice of ore dressing in Boulder county, Colorado, was discussed recently by Mr. Herman Fleck.

The brecciated nature of much of the ore offered difficulties that were overlooked in early days, permitting about half the tungstate of iron, ferberite, to pass into the tailing-ponds. The problem is affected by a two-fold difficulty, namely, the friability of ferberite, whose perfect cleavage has been noted, and which produces thin plates of mineral all too readily slimed by the action of stamps. In a measure, this has been overcome by a better demand for concentrates containing from 25 to 40% and by apparatus devised to treat the slime rejected in older practice. In the one case the increased density of the horn-stone, due to enclosed ferberite, allows coarser crushing, and subsequent separation from the gangue. In the other, modern slime-tables and canvas-tables prevent much of the ferberite, unavoidably slimed, from going to waste. Again, with the first instance in view, still coarser crushing, sizing, and jigging, followed by full use of present practice, have been suggested; but apparently without producing a change of general method. As it is, with increased use of the expedients mentioned, a recovery of 65% is made possible on more refractory ores, and recoveries of 85% are common. Two examples will suffice to describe current practice.

1. The ore is passed over a 2-in. grizzly, from which the undersize is fed to stamps and the oversize to a 7 by 10-in. Gates crusher, thence to the mill. The latter consists of 20 stamps of 1000 lb. each with a six-inch drop from which the ore, crushed to 20-mesh, passes to a special classifier, which delivers the coarse to two No. 5 Wilfley tables, middling to one No. 3, and the slime to two No. 3 tables. The coarse concentrate forms one product, while concentrate from the middling and slime are combined into a second product. Tailings from all the tables are tanked and distributed to four Wilfley slime-tables, from which the tailings are rejected, the concentrates being combined to make a third product and the middlings sent to an additional Wilfley slime-table where a final concentrate is collected. The capacity is 25 tons per 12 hours, the average concentrate being 15:1.

2. The ore is passed over a 2-in. grizzly, the undersize going to stamps, while the oversize goes through a 7 by 10-in. Gates crusher into a battery of 10 stamps, 760 lb. each, making an 8-in. drop 64 times per minute, and through a 12-mesh screen. Two No. 5 Wilfley tables receive the pulp, yielding a high-grade concentrate, the tailing going to a settling-tank, thence to classifiers. The coarse is sent to a 4 by 12-ft. Frue vanner, the middling and slime to two 6 by 12-ft. Frue vanners. The concentrates from middlings and slimes are combined. The tailing from the coarse vanner is run through a Huntington mill with a 60-mesh screen and then to canvas tables. The tailings from the other two vanners go to a V-settling tank, from which the pulp is treated by four vanners and the overflow goes to canvas tables. The latter, two sets 12 by 40 ft. each, have a slope of 1 in 12.

A typical analysis of high-grade concentrate is as follows:

	%
Tungstic oxide	59.39
Iron oxide	32.57
Sulphur	0.00
Manganese oxide	1.02
Phosphorus	trace
Silica	8.32

It will be noted that the mineral proper constitutes nearly 90% of the product.

Nearly all the mills do custom work, and settlement varies from purchase of ore outright on a sliding scale to a fixed price of $3 to $4 per ton for concentration, and purchase of the resulting concentrate at the market price. A sliding scale is graduated from 1 to 4%; 5 to 9%, etc., and in terms of cents per pound of tungstic oxide present in the ore or concentrate up to 60%.

Magnetic separation has been tried with some success. Where the ore contains arseno-pyrite, or pyrite, or both, experiments on direct treatment with electro-static machine have proved successful. In practice wet concentration is usually first employed, and the dried mixed concentrate is roasted to make it magnetic, after which the contaminating minerals are withdrawn in the magnetic field of a separator. Such is the case with Nova Scotia scheelite. With wolframite and tin ore a differential separation by magnetic fields of varying intensity may be used. The Cornwall tungsten ores are thus treated, making a separation of the above from iron oxide, and then from one another.

AMONG RECORD MILL-RUNS, as recently related by a mining engineer of wide experience, was a notable performance in 1878 at the mill of the old Syndicate gold mine at Bodie, in Mono county, California. A million dollars was produced in six weeks from a 20-stamp mill when the supply of ore was only sufficient to supply an average of 7 stamps. During the six weeks a total of 1600 tons of ore was crushed, making the recovery over $600, or 30 ounces, per ton. On one occasion the engineer in charge reported a yield of 900 pounds of gold amalgam in one day; the general office thought this must be a mistake and that he meant 900 ounces. "To one familiar with the sound of the stamps when in regular operation," he relates, "it is interesting to state that occasionally the free gold filled the inside of the mortar so that a peculiar soft impact was heard instead of the customary pounding of the stamps. No amalgamation was attempted in the mortar, but the pans sometimes got choked with amalgam so as to hinder operation; the amalgam accumulated on the side-wings of the pans so as to jam the mullers and slow-down the mill-engine. So much retorting was done that for days at a time the retort had no chance to get cold." The choking of a mortar-box with amalgam occurred several times at the old Caledonia mine on the Thames, New Zealand, 40 years ago. This mine yielded 10 tons of gold in a year.

AN EXTEMPORIZED STAMP-MILL.

A CLOSE VIEW OF THE MORTAR-BOX.

A Rock-Drill Stamp-Mill

By C. F. Weeks

MANY a mine superintendent has felt the need of a more thorough method of prospecting orebodies he is opening than by the assaying and panning of marked samples, before it is advisable to build even a small mill of the regular type. This need has been met by the South Fork Gold Mining Co. at Forest, Sierra county, California in the following manner. The company had purchased a Temple-Ingersoll electric air-drill, for the purpose of extending the hard-rock tunnel for gravel, and did 400 ft. of work along that line. Since then attention has been given to developing one of the lodes where the rock is not hard or solid enough to stand a power-drill. The drill not being in use, it was thought that it could be made serviceable as a one-stamp mill; on account of the heavy blow that it strikes and because of the low cost of operation, it has answered the purpose exceptionally well. Working in this capacity, the drill uses 2½ hp. and crushes a ton of hard quartz through a No. 1 screen in 14 hours, striking 220 times per minute with the motor operating at half-speed, which is not the regulation rate, but the motor does not show any ill effect of continuously running at half speed. The drill is mounted on a tripod that in turn is held by heavy timbers, which are anchored to the solid rock. The construction of the mortar is simple as well as substantial. It is composed of a 30-in. length of 6-in. standard pipe shrunk on a soft-iron casting with a square base having four holes for anchor-bolts. The casting and the hard-cast die, which is 4 in. diameter and 6 in. high, were cast at the foundry, and with these exceptions, the entire mill was constructed in the blacksmith-shop of the company, which is in no way exceptional in equipment. The stamp is made from a piece of 1¼-in. drill-steel upset to 4 in. at one end and shanked for the drill-chuck at the other. The screen-opening is 8 in. high and cuts out half of the mortar. The screen-frame is built of iron in such a manner as to place the screen on a 2-in. offset at the top and an inch at the bottom. The feed-chute is connected directly at the back of the mortar and is made of 20-gauge galvanized iron and fastened with screws to the mortar in which the opening is 3-in. square and on a level with the discharge. The lip of the mortar is also of 20-gauge galvanized iron and is securely screwed and clamped. The mill is equipped with the ordinary type of jar-feeder, which is easily constructed and is efficient when properly adjusted. Then follow second-hand silver-plated copper plates, a foot wide, 8 ft. long, with a half-inch drop per foot. Owing to the fact that the clearance of the stamp in the mortar is small, as compared with the usual type of mill, the crushing capacity is exceptionally large, while for the same reason inside amalgamation is poor. This, of course, could be remedied by increasing the size of the mortar, and so allowing more chance for amalgam to settle. But when the gold is readily amalgamated as is the case here, this type of mill gives excellent results.

BRAZIL has an area of 3,292,000 square miles, which is greater than the United States exclusive of Alaska, and a population of 24,000,000, which is one-quarter of that of the United States; Rio de Janeiro, the capital, has 1,500,000. Portuguese is the national language. Ocean-going steamers can ascend the Amazon to Manaos, a thousand miles inland. Shipments of iron and steel, machinery, and oils from the United States is increasing rapidly.

Treatment of Miners' Injuries

By T. C. Witherspoon†

*Every wound, whether it is large or small, is of interest to the sufferer. In every wound, that is, where the skin or mucous membrane of the body has been broken, there lies the possibility of an inflammation which may become serious. On this account no injury of this sort, whether it be a simple abraded skin, a clean cut, or a jagged, extensive opening into the tissues, should be neglected.

Treatment of open wounds is simple, but must be done with some intelligence. Nature is the chief physician whose aid never fails if due attention is paid to her laws. When a wound is made there is an immediate oozing or bleeding from its surface, and in this blood, or serum, there is nature's first application of an antiseptic. The living blood has a certain resistance to inflammation-producing germs, but the dying blood, such as that which escapes from a wound and clots upon its surface, is many times more destructive of germ life than the living; therefore, this blood which is being exuded on the surface of the wound is the first great antiseptic application, washing away infection directly from within outward, and helping to destroy the germs that may have been implanted by the injury.

To this should be added the surgeon's aid. It was a practice in olden times, and even until recent date, to immediately wash these wounds with a solution containing carbolic acid, corrosive sublimate, lysol, iodine, or some antiseptic agent. The idea was that in washing the wound it was cleansed, and in the application of a dilute antiseptic the germs present were killed. From much experience and tedious experiment the medical profession has definitely proved that, instead of cleansing the wound, washing more often carries germs into it, and the antiseptics used are so dilute that instead of destroying germs they are practically useless. On this account wounds that were washed most carefully were often the wounds which inflamed and developed pus shortly afterward. Through this knowledge it became apparent that the best way to treat a wound was simply to protect it.

Sometimes when wounds result from instruments probably holding highly poisonous germs, or in places where such poisonous germs are likely to be found, it is necessary to use some measure to destroy such as might have been carried into the wound. To do this two agents are best used: one a concentrated tincture of iodine, and the other pure carbolic acid. In a wound where infection is suspected, it is a good plan to drop into it some tincture of iodine. If, however, there is good reason to believe that the wound is seriously infected, the surgeon usually makes an application of pure carbolic acid to its entire surface, then wipes it dry of all excess. This, when done immediately or shortly after the injury is received, will practically always prevent germs from growing in the wounds.

One other hindrance to the healing of wounds is the presence of some foreign matter like rock, splinters, or small fragments of metal. As a rule, these particles do not carry serious infection in with them, but in all cases they should be removed if this can be accomplished without too much further injury to the already wounded tissue. They can never be washed out well, therefore, here again water or antiseptic solutions are out of place. Small forceps or dry pieces of gauze are used to remove these foreign bodies, purely by mechanical means.

The use of peroxide of hydrogen in or on wounded surfaces has been often advocated. This will be found to be a mistake. It diminishes the antiseptic action of the blood on the wounded surface, and does not offer a better antiseptic or even one nearly so good in its place.

It must be especially remembered that wounds through skin that is blackened by coal dust or dirt from working about engines, are certain to be made worse by any effort to cleanse the skin about the wounds. Such a wound should be most carefully dressed dry, without washing, usually in addition to the application of iodine or the mild cauterizing of its surface with carbolic acid.

In summarizing, it may be said that simple wounds dressed dry and unwashed, or touched with carbolic acid or iodine, heal better than when they are washed with any solution whatever. Larger wounds must be treated the same way, cleansed of foreign bodies mechanically and dressed dry. If these wounds are washed they always suppurate or have matter formed in them. This knowledge of the conduct of wounds has led to the present day simple first-aid package that every soldier carries with him into battle. Regardless of the nature of a wound he receives, it is dressed with a dry piece of gauze and usually left untouched for several days. By this system results have become much better in warfare, and soldiers are returned to the front in much shorter time.

†Doctor at the Murray hospital, Butte, Montana.

*Abstract from *The Anode*.

OIL PRODUCTION FIGURES of the different states for 1915 show that California ranked first with 89,000,000 barrels, Oklahoma was second with 80,000,000, while Texas, Illinois, and Louisiana follow in the order named. The old oil-producing State of Pennsylvania produced nearly 9,000,000 barrels, ranking seventh between West Virginia and Ohio; Wyoming is ninth, and Kansas tenth.

THE ALTA-COTTONWOOD area of Utah now has 70 operating mines employing 700 men, as compared to a year ago when there were 17 mines employing 100 men.

Mining in Western Oregon

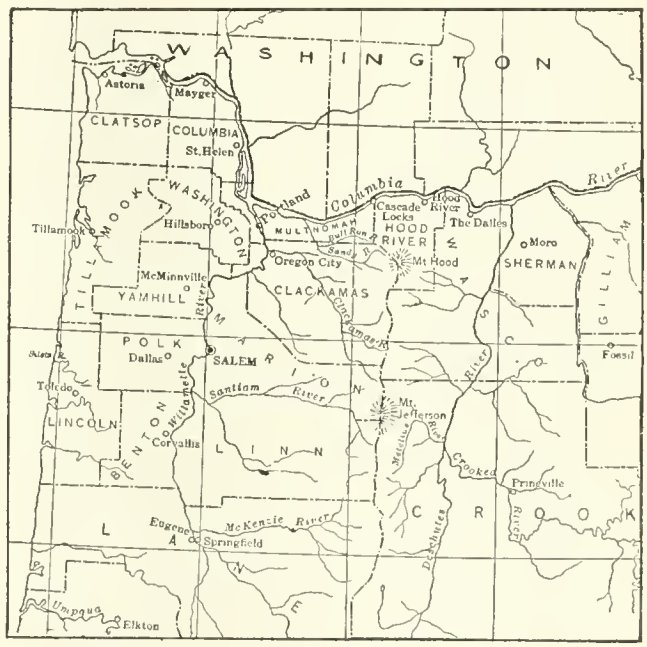
By E. C. Morse

THE Bureau of Mines and Geology of Oregon formerly issued a monthly publication describing the State's mineral resources. The districts touched upon included the mines of Jackson and Josephine counties in southern Oregon; north-eastern Oregon, with its Virtue mine and its production record of $3,000,000 near Baker City; the old mines along the Mother Lode near Bourne in the same county comprising the North Pole, and the Excelsior and Eureka, better known as the E. & E.; the Columbia and the Goleonda mines, with an aggregate production of over $8,000,000; the successful dredging operations of the Yuba Construction interests (Powder River company) near Sumpter; the modern mining and milling plants of Mormon Basin and Cornucopia; the possibilities of the Susanville district; the dredging opportunities along John Day and Burnt rivers. The Bureau did not continue this work during 1915, probably because of a shortage of funds, and did not describe the porphyry dikes of the Cascade mountains in Clackamas, Marion, or Lane counties, the cinnabar prospects near Prineville, nor the lava-capped gold-bearing sand deposits along the Deschutes river. A description of these porphyry deposits is the chief purpose of the present article.

The mines of the Bohemia district were paying good dividends about 15 years ago. The Champion, Music, Helena, and Noonday were the principal groups; each had a 10-stamp mill. The Helena produced some bonanza ore and is supposed to have ore of about $6 grade still in reserve. The Champion and Music also had rich shoots or chimneys and made profits with their small reduction plants as long as they continued to mine in the oxidized zone and the gold could be recovered by simple amalgamation. When they became deeper the ore proved refractory and low-grade sulphides appeared containing iron pyrite, arsenopyrite, galena, blende, and some chalcopyrite. The metallurgical problems were then beyond the pioneer operators, who sold their holdings to an Eastern syndicate, which consolidated the three leading groups, the Champion, the Music, and the Helena, the resulting corporation becoming known as the Oregon Securities Co. A hydro-electric plant was erected and the three 10-stamp mills were combined into one 30-stamp mill, a central hoisting-works was built, and a subsidiary company extended the local railroad from Cottage Grove to within a few miles of the property. But no serious effort was made to overcome metallurgical difficulties; so the concern failed.

Later a group of lumber-men from Kelso, Washington, operated the Champion mine under lease and made a profit. At present the West Coast Mines Co. is re-opening the mines; this company is reported to have opened up shoots of oxidized ore and to be shipping concentrate from the sulphide zone. The management is improving the equipment, putting the stamps on concrete foundations, adding modern concentrators, and expects to be in full swing shortly.

The Lucky Boy mine has an interesting history, and also a promise of profitable production if properly equipped. It may be roughly described as a group of chimneys and shear-zones in an altered dike of porphyry within an andesite country. It paid good profits while operations were confined to the oxidized zone with a



NORTH-WESTERN OREGON.

15-stamp mill. In several places in the oxidized zone it was stoped for a width of 40 ft. and yielded gold on the plates at from $4 to $6 per ton. About 12 years ago a 40-stamp mill with a full outfit of Wilfley tables and Union vanners was installed on the property. There was also developed a good hydro-electric power with a double Leffell turbine and a Westinghouse 250-kw. generator. The power was developed on the McKenzie river several miles above the village of Blue River. About the time this plant was put in operation, the ore changed with depth from a free to a sulphide character, yielding a bulky low-grade concentrate that would not stand the expense of the 50-mile wagon-haul necessary to reach the railroad at Eugene or Springfield. So the project failed. Before the attempt was abandoned, an effort was made to recover the precious metals in the concentrate by a so-called secret process, including re-grinding in an old Crawford mill, treatment of the

pulverized concentrate with a 'secret' solution, and the amalgamation of the gold and silver contents on shaking electric plates. Needless to say the scheme was not a success.

In 1908 I built a small cyanide plant to treat the accumulated concentrate. The plant consisted of the Crawford mill already mentioned, some small Pachuca tanks, a filter of the Holderman type, and a zinc-shaving precipitation equipment. The experiment was not a complete success, owing to the inadequate grinding facilities, which were unsatisfactory not only by reason of not properly releasing the gold and silver contents for cyanide contact, but also in leaving a heavy product difficult to agitate. During this test special runs were made; these demonstrated that more than a 90% extraction was possible whenever the material was pulverized fine enough and good agitation accomplished.

Neither the quantity of concentrate on hand, nor the condition of the mine justified going farther at that time. The deeper ore of the Lucky Boy mine is for the most part altered porphyry containing streaks of spar and about 10% of pyrite with large lenses of galena and blende and some chalcopyrite. The ore is undoubtedly suited to the modern process of gravity concentration and flotation. A lead-silver, zinc, and possibly a copper product can be made rich enough to ship to the smelter, while the low-grade iron-sulphide concentrate can be ground to 200-mesh and cyanided on the ground. There are places where crude ore can be mined rich enough for shipment. The old company hardly tested the deeper ore before ceasing to operate. The present owner, the Consolidated Lucky Boy Mines Co., has spent a small amount of money on two adits, one about 300 ft. below the lowest former operations and another about 600 ft. deeper than the old workings. The latter has not yet reached the zone or dike. The former has exposed ore of low grade and some good lenses of galena. One cross-cut contains concentrating ore for a width of 40 ft. with a strong galena showing on one wall. This adit has not yet reached the ore-shoot that yielded the good ore in the upper workings and will have to be driven several hundred feet to reach the Daisy Creek intersection, where the best ore was found. Driving this 'tunnel' through to the Daisy Creek intersection would be a good speculation for a development company.

The Ogle mountain mine is situated in Clackamas county near the line with Marion county, and is about 40 miles east of Salem in the foot-hills of the Cascade mountains, not far from the base of Mt. Jefferson, between the Molalla and North fork of the Santiam rivers, two tributaries of the Willamette. By the road used at present, by way of Mt. Angel and Scott's Mills, the mine is 40 miles from a railroad. When the road by way of Gates is available, the distance from railroad transportation will be 12 miles. A fair mountain road is possible by this route.

Work has been conducted at this property by an association of local people. The mine has been opened by three cross-cut adits. The first crosses the dike at a depth of 50 ft., the second at 300 ft., the third at about 900 ft. Drifts have been extended on all these levels. A number of shear-zones and veins have been encountered and the main dike averages about 50 ft. in width. The lower adit crosses six veins or zones with assay values of interest in most of the dike matter, with enrichments in the form of lenses. This 'tunnel' is 1160 ft. long. There is pyrite all through the lower orebody, thus when reduced to a clean concentrate will assay $75 per ton. Galena occurs in lenses much as in the Lucky Boy, but it carries a higher gold and silver value. In the upper workings considerable free gold is present, generally in the same form as the galena; enrichments occur in the lower workings.

There was formerly a 10-stamp mill that saved the free gold only, and a fair showing was made with it. Later a cyanide plant was built; this includes a steam power-plant, a new rock-crusher of the Traylor roll-jaw type, a Traylor 5 ft. by 22 ft. tube-mill, three agitators of the Spalding type, each 20 ft. diam. by 20 ft. deep. They were intended to be hydraulic agitators with an arrangement similar to the Parral tank, except that it was meant to be actuated by a 2-in. centrifugal pump for each tank instead of by compressed air.

Both pumps and compressors were insufficient in capacity and the agitators never worked in a satisfactory manner on the heavy sulphide contents. This material should have been separated by concentration for separate treatment. All the iron sulphide contents as well as the finer gold, after the coarse gold had been removed, are adapted to cyanidation when the material has been properly prepared.

The company was the victim of an inventor with a theory. Unfortunately when building the cyanide plant the stamps and plates were dismantled, leaving no facilities for catching the coarse gold. The omission of the 10 stamps also rendered the coarse-crushing capacity inadequate. These mistakes could have been easily corrected had the company not exhausted its financial resources before it realized its position. The outbreak of the European war made it impossible to raise money. An attempt is being made at present to resume operations on an adequate scale. Some galena has recently been exposed in the No. 2 vein in the lower adit. An effort is being made to connect the upper workings with the lower adit by a raise, to determine the continuity of the orebody as well as to improve the way of getting ore from the upper workings to the mill.

About a year ago some excitement was created in Portland by the announcement of the discovery that vast bodies of partly-cemented sand, much of it lava-capped, along the Deschutes river contained gold that could be recovered by a combination process, using concentration followed by cyanidation. Experienced mining men have been skeptical, but a mining engineer of experience who made an examination of the deposit has reached the conclusion that it is at least worthy of an investigation.

Mining in Arizona

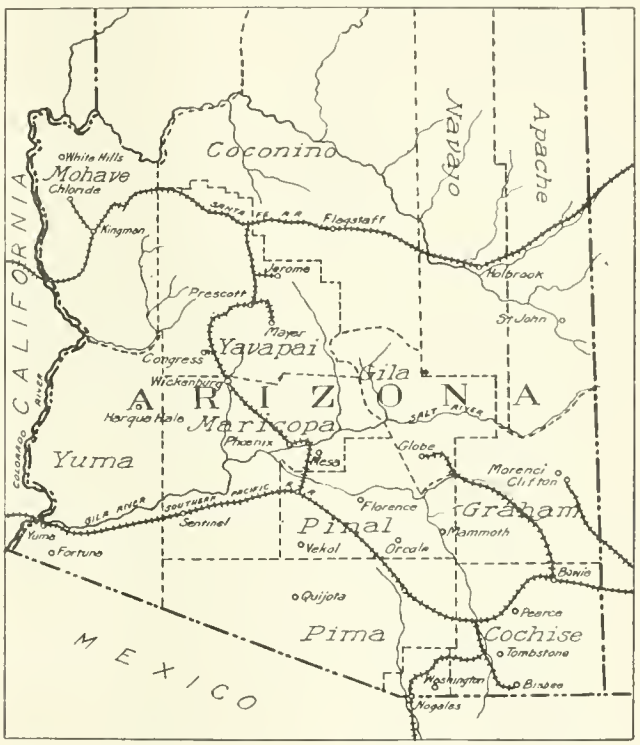
By Charles F. Willis

A RECORD of production was reached in 1915, the aggregate output of gold, silver, copper, lead, and zinc amounting to a value of about $90,000,000, as compared with $60,000,000 in 1914. Yet there are still brighter prospects ahead.

During the past year the Old Dominion mine was curtailed in its production for two months by a flood, which drowned the lower workings, and prevented the operation of the plant and the production of 5,000,000 pounds of copper. The loss of about 28,000,000 lb. of copper was incurred by the shutting-down of the mines in the Clifton-Morenci district, because of labor troubles. The International Smelting & Refining Co. started to produce copper in the month of June, and has not yet reached its normal capacity of 150,000,000 lb. annually, as the Inspiration mill, whose concentrate it is to handle, is not entirely completed. Twenty-five per cent of the copper produced in Arizona will come from this plant. The smelter of the United Verde Copper Co. was blown in during the year, and although its capacity is double that of the old plant, it has been gradually increasing to its full capacity, but has not yet reached that point. During the year the Miami Copper Co. has gradually increased its tonnage from 3500 tons daily to 4200. The experimental work of this company has proved the feasibility of treating their low-grade ores, which run 1.21% copper, and it is believed that this plant will also rehandle the main tailing-piles that have been made by the Miami mill. The New Cornelia at Ajo has completed its railroad, and work will now be rushed on the construction of a leaching plant using the Greenway process, where 4000 tons per day will be treated. This and its sister property, the Ajo Consolidated, will prove great additions to the copper production of the State.

While copper in 1915 reached 450,000,000 lb., or almost 25% of the production of the United States, it should reach over 600,000,000 lb. in 1916. This alone will increase the gold and silver production, as most of the copper ores contain small amounts of the precious metals.

This, however, is but the beginning. Publicity has been the key-note of Arizona's progress for the past few months and will continue to be so during the next year. For many years it has been known that the Oatman district contained gold ore in large enough quantities to make profitable mines, and that there were large veins traversing the district. For many years two companies, the Tom Reed and the Gold Road, consistently developed, mined, milled, and earned profits, but the development of the district did not follow in the footsteps of these producers. It was known that the orebodies of the district were wide and long, and that the ore was free-milling and cyaniding, but the knowledge of these facts alone did not mean the development of the district, in spite of the fact that there are many lodes existing under as promising conditions. Consistent, truthful, and persistent publicity told the world of the Oatman district, and in one year more development has been done, more mines have been found, more properties have changed hands, and more men have been put to work than would have taken place in several decades in the ordinary course of events. Hundreds of carpenters are at work



building a town; shafts are being sunk everywhere, all with the idea that development must go at least 500 feet. Many operators are complaining that they cannot get their head-frames, hoists, and compressors. It is a real boom, with four mines, the Tom Reed, Gold Road, United Eastern, and Big Jim assured.

Following in the footsteps of Oatman comes the notice of publicity work on the same lines from Yavapai and Pima counties. The advertising of their resources will bring to the attention of the investing world the possibilities of these districts. The boom at Oatman, and the fact that it has called attention to Arizona, is going to assist in the development of the wonderful resources of both Pima and Yavapai counties.

Copper and gold are not the greatest of the State's activities, however. The tungsten fever is raging, and the past few months has seen an extensive development of new properties. The old dumps of the early-day

silver-chloride mines are being investigated, and in many cases the tungsten character of the product has resulted in relocations. The many samples being sent to the Arizona State Bureau of Mines for identification indicate that there are a number of prospectors looking for tungsten, and many of them finding it. Records show that there are 26 producers of tungsten ores in Arizona, most of them in deposits of considerable size, although some will undoubtedly have to stop mining when the price of the metal drops. The Arivaca, Dragoon, and Globe districts are the largest producers.

Molybdenum is also coming in for its share of attention, and is being produced from many localities, although the greater part of the production has been from the Mammoth district, from which 30 tons of 21% wulfenite concentrate is being shipped monthly, for which a remarkably high price is being paid. Throughout the State are scattered many large deposits of molybdenite, associated with copper, and in the Copper Basin district a new process is being installed to work the ores of the Copper Hill mine. The flotation research work of the State Bureau of Mines, by H. J. Stander, has shown remarkably good results in selective flotation in separating molybdenite from the copper sulphides, using as low as 0.0025% fusel-oil.

In addition to the deposits of quicksilver that are already known in northern Gila county and at Ehrenburg, a new deposit has been found in the Copper Basin district, Yavapai county, by Messrs. Ross, Hall, and McNary. This find has created considerable excitement in Yavapai county, and has started a score of prospectors in search of mercury.

Tungsten hunters have found other things, notably a deposit of stibnite in the Turkey Creek district by Messrs. Ryan and Rogers of Mayer. It is reported that the pay-streak is fully two feet wide, and may be traced for over a mile. This is the only deposit of commercial antimony that has been found in the State.

Much placer exploration is going on in various localities, including the Lynx Creek, Dos Cabezas, Quartzite, Hassayampa, Le Paz, Old Hat, San Domingo, and Arivaca districts. There are many deposits of placer gold in Arizona that would be considered rich if water were available, and the one who can devise a method of working the great quantities of material in these areas cheaply and using little water will be rewarded by much gold.

With the stimulation of the industry in tungsten, molybdenum, quicksilver, antimony, and asbestos, Arizona is coming forward in the rare-metal production. The present high price of copper and the change in the sliding scale of wages at the larger camps to include 25-cent copper, has greatly increased general prosperity.

COPPER PRICES in New York in the summer of 1861 were between 17 and 20 cents per pound. That was at the beginning of the Civil War; prices gradually rose to 50 cents per pound in 1864-5, then declined until in 1870 they were again about 20 cents.

Copper and Aluminum

As is generally known, copper is a better electrical conductor than aluminum; and mechanically, it is much stronger; for equal cross section aluminum has about half the strength of copper; and for the same electrical conductivity the breaking point of aluminum wire is about 80% that of copper wire. This means that on a power-transmission line, the aluminum wire would break from 80% of the strain required to break the copper wire, assuming that neither wire was scratched or nicked. Aluminum, being quite soft, is more liable to slight mechanical injuries from erecting or handling. Sudden breaking of aluminum wires occurs from time to time by reason of injuries suffered during erection. An arc, due to a short circuit or to wires momentarily swinging together, may cause serious damage to an aluminum line on account of the low fusing point of aluminum, thus burning and pitting the wire, and reducing the mechanical strength. With copper, however, the arc has little or no effect. Aluminum is cheaper than copper when the two are compared merely on the basis of conductivity, and will furnish more conductivity for a dollar than copper. For the same conductivity aluminum is considerably lighter than copper, the ratio being 2 to 1. This might indicate that lighter towers could be used. Experience shows that the reverse is the case, because it is not the dead-weight of the line that determines the necessary strength of the tower, but the strains caused by winds. Aluminum has a cross-section 64% larger than the equivalent copper wire, therefore offers more resistance to the wind and causes a greater side pull. Under sleet conditions a greater area of sleet will collect on aluminum than on copper, and at such times there are generally strong winds. Aluminum, on account of its greater coefficient of expansion and low tensile strength, requires higher towers, or towers placed closer together. Aluminum is not suitable when there is abrasive action on a wire, such as trolley wire, nor is it suitable for smaller sizes of wire, such as telephone wire, which is invariably of copper. Copper is better suited for cables and insulated wires on account of its smaller diameter and equal capacity.

SPAIN, it is reported by *Ingenieria*, an engineering periodical of Madrid, is to produce platinum from deposits discovered in the southern province of Malaga. The report states that Domingo de Orueta, a Spanish engineer, made the discovery in the Ronda mountains where he had noticed a similarity to the great platinum-producing areas of the Ural mountains.

"MISDIRECTED OPTIMISM," said the manager of a large successful mining company who was in the office recently, "has been the cause of most of the mistakes in judgment made at our mines." Intelligent criticism, it should be recognized, is not pessimism; it constitutes a valuable contribution to the rewarding of real merit.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

TUNGSTEN melts at 3540°C.

DIAMONDS have been found in the banket of the Simmer Deep mine, on the Rand. They are also found in the mortar-boxes in the Klerksdorp district mills.

AN AERIAL TRAMWAY at the Weedon copper mine near Weedon, Quebec, transports ore 19,500 ft. to the railroad at a cost of 6.7 cents per ton. About 10,000 tons is moved per month.

A SQUARE ACRE of land measures 208.7 ft. on each side and contains 43,560 sq. ft. In a mining claim 600 by 1500 ft. there are 20.66 acres; in a square area of ¼ mile on a side there are 40 acres.

CONCRETE tests at the Sheffield Scientific School as to the best proportion of water in concrete showed that a 1:2:4 mixture, tested after a set of 30 days, was strongest when it had been mixed with 27½% of water.

A PLAYA is a shallow, flat-floored depression characteristic of valleys having no regular drainage to the sea, in which storm-waters collect and evaporate—a wet and dry lake. It may be a shallow lake or a salt-incrusted mud flat.

ALUMINUM has the property of withstanding the action of nitric acid and sulphuric acid, either separately or combined, making the metal valuable in the manufacture of high explosives. Hydrochloric acid, however, attacks aluminum readily.

USE OF OIL in generating power is much more effective when applied to internal-combustion engines than when consumed as fuel under boilers. In the one case a barrel of oil gives power for crushing 14 to 15 tons of ore; in the other only for 1¾ to 2 tons.

COLLOIDS is a term now used by many chemists, especially those uncomfortable amid the complex physical problems underlying flotation, when they are at a loss to explain themselves. Much in the same way the 'geyser' was the last resort of the perplexed geologist in an earlier decade.

FIRE-BRICKS at smelters become impregnated with copper sulphide, lead sulphide, metallic zinc, and zinc oxide, and according to N. B. Davis in *Economic Geology*, the blast-furnace may be adapted to an experimental method on a large scale for the elucidating of problems of ore deposits of several important types.

THE COMPRESSION OF AIR develops heat, and if a mass of air is compressed to one-fourth of its original volume, its temperature will be raised to 376°F., if no heat is allowed to escape. Since the air thus compressed is allowed to cool to the temperature of the surrounding atmosphere before it is used, the mechanical equivalent of this dissipated heat is work lost.

THE AMOUNT OF GOLD that a strong man could carry would probably not exceed 360 lb. avoirdupois, which in fact he would not want to carry any great distance. This amount of gold represents about $100,000 and if formed in a solid sphere would be but 10 inches in diameter. A ton of gold (2000 lb.) is worth $602,861.

HARDENING OF CONCRETE is accelerated by the use of calcium chloride, according to the U. S. Bureau of Standards. It was found that 4% of calcium chloride added to the mixing-water increased the strength of the concrete, at the age of one day, 100% or more. In some cases the strength of two-day old concrete mixed with calcium chloride was as much as 75% of the strength of ordinary-mixed concrete at the end of a month.

THE NITRATE INDUSTRY of Chile is of the greatest importance to that country. The aggregate exports up to 1915 were valued at $1,702,574,394. During the last three years, the respective outputs were: 58,751,291; 32,070,714; and 46,000,000 quintals of 101.445 lb. The export duty is now 56c. per quintal. The selling price at the vessels is $1.81 per quintal. It is said that the cost of production can be reduced. When the War started the nitrate business was affected considerably; but now there is a large demand for the product.

ENORMOUS QUANTITIES of natural gas have been wasted in the past, large quantities still are being wasted, but a reduction of this waste is taking place owing to the proper capping of wells. Probably the most novel way of conserving gas is that by the Standard Oil Co. in the Midway oilfield, California, where two wells are yielding more gas than is needed for fuel or domestic purposes in the field, so instead of permitting the gas to go to waste it is carried by pipe-lines to a hole that was drilled for oil several years ago. Under natural pressure the gas finds an outlet at about 500 ft., and apparently is being stored away in underground reservoirs at that depth.

SLIPPERY METAL FLOORS, stair-treads, elevator-landings, and manhole-covers are so dangerous that casualty insurance companies are now making extra charges for such hazards, according to *The Anode*. Owing to the nature of operations at smelters it is necessary that metal floors, stairways, etc., be used. It is, however, possible to greatly reduce the slipping hazard by roughening the metal surfaces, or by using some of the slip-proof surface materials that have lately come into use. Engineers engaged in smelter construction seem to have a weakness for designing stairways that have a steep inclination and have so far paid little attention to the matter of making them safely and comfortably usable.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

WAGE INCREASE—NORTH BUTTE ELECTRIC HOIST—TUOLUMNE, BALLAKLAVA, AND BUTTE-ALEX SCOTT—ANACONDA'S NEW ZINC MINE—ELM ORLU BUTTE & SUPERIOR DECISION.

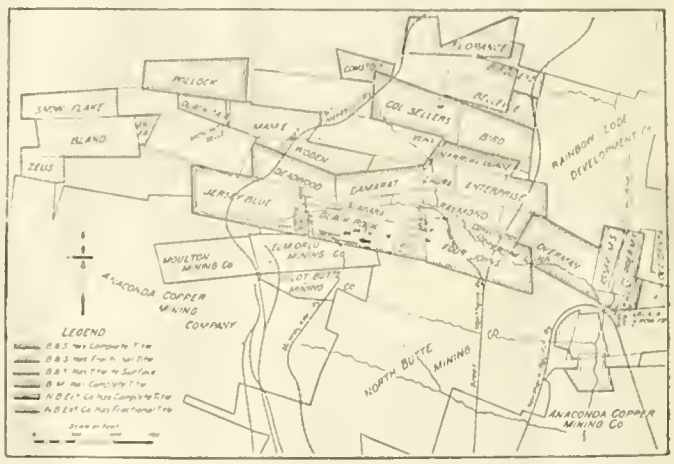
Wages of miners working in the Butte district have been raised 25c. per day. 'Muckers,' miners, and timbermen are paid the same amount, and all underground men now receive $4.25 per day. There had been an agreement between the operating companies and the Western Federation of Miners that wages should be $3.50 per day when the average price of copper was below 15c., from 15 to 17c. the scale was to be $3.75, and above 17c., $4. The contract was cancelled during the union troubles here, but the companies have voluntarily adhered to the terms of the old agreement. $4 was the maximum under the old scale, but since it appears that the price of copper may be over 20c. per lb. for several months the companies agreed among themselves to share their large profit with their employees, and wages were raised to $4.25. When copper drops below 20c. wages will again become $1. The increase affects about 19,500 men at Butte, and raises the monthly pay-roll of the mining companies to $2,150,000. The men working for the Anaconda company at Anaconda and Great Falls will also receive a raise of 25c. per day.

The motor of the new electric hoist at the Granite Mountain shaft of the North Butte has burned out. It was of 1750 hp., and was thought to be powerful enough for the work, but experience has shown that it could not sustain the trying conditions that a hoist of this nature is subjected to. It will require at least a month to re-wind the motor and have the hoist in working order. The old steam hoist at the Speculator shaft is again in commission, and ore is being hoisted at nearly normal capacity. Some shareholders have expressed dissatisfaction with the high costs at North Butte during the past year. Those can be attributed largely to the extraordinary expense incurred in connecting all the levels of the Speculator mine with the Granite Mountain shaft. This gives the company two fully-equipped operating shafts, and in case of accident to one, nearly full capacity can be hoisted through the other. The wisdom of the expenditure is shown clearly when one considers what the company would lose from a shutdown of a month during the prevailing high price of copper.

The Tuolumne did not meet expenses during December, and it was rumored that the mine would be shut down. However, the ore is now of a better grade, and the directors have decided to keep the property in operation until the annual meeting of shareholders held in March. The Tuolumne is a fractional claim with an area of only six acres. It is surrounded by ground of the North Butte and Anaconda companies. Negotiations have been opened for the sale of the Tuolumne, and if the price fixed by the stockholders is low enough, a sale is possible to either of the larger companies. Because of their better facilities they would be in a position to make a profit from ore that will not pay expenses under the prevailing conditions.

A cross-cut from the bottom of a winze on the 1800-ft. level of the Ballaklava has cut a vein that averages 3% copper for a width of 24 ft. The new orebody will be blocked out as rapidly as possible, and when it is in shape production will be increased from 150 to 350 tons per day. The shaft will be sunk later to 1800 ft., but for the present the ore will be hauled through the winze.

The Alex-Scott will probably be sold to the Anaconda company. The directors of the two companies have agreed on the terms of the sale, and the proposition will be put up to the stockholders of the Butte-Alex Scott for ratification. The Anaconda company offers $50,000 cash for the property, which is a fractional claim surrounded by claims of the Anaconda. The Butte-Alex Scott owns the Edith May vein, and the Anaconda owns the Colusa vein. The veins intersect, and there are stringers running from one to the other, so that the question of ownership is difficult to decide. The sale will make unnecessary a law-suit that would be inevitable if the Butte-Alex Scott continued to operate as an Independent company.



PLAN SHOWING BLACK ROCK CLAIM, THE SUBJECT OF DISPUTE.

On January 22 at Butte, Judge George M. Bourquin gave his decision in the Clark-Montana Realty Co. and others (the Elm Orlu Mining Co.) *v.* the Butte & Superior Copper Co. extra-lateral suit. The finding briefly was as follows, the full decision covering two pages of *The Butte Miner:*

1. That the Elm Orlu claim was located before the Black Rock claim was located.

2. That the north wall of the Rainbow vein apex crosses the common side-line between said claims 190 ft. from the southwest corner of the Black Rock claim, and that the south wall of said vein apex so crosses 301 ft. from said corner.

3. That the Pyle strand of the Rainbow vein diverges from the south side of the latter vein in the Elm Orlu claim, and there and for some indefinite distance easterly has its apex in the Elm Orlu claim.

4. That the Jersey Blue vein apexes in the Black Rock claim, does not unite with the Rainbow vein, and crosses on strike and dip the Rainbow vein on strike east of the Rainbow apex crossing of the common side-line.

5. That the Creden vein diverges from the north side of the Rainbow vein in the Elm Orlu claim and has its apex in both the Elm Orlu and Black Rock claims.

6. That the apex of the easterly strand of the Rainbow vein in the Black Rock claim terminates at a point within said claim east of the Elm Orlu east end-line projected and about 250 ft. west of the Black Rock east end-line.

7. That prior to the Black Rock location and patent entry both the Rainbow vein and the Jersey Blue vein at their apices were discovered, and known within the Black Rock claim, and at their apices appeared as a continuous east-west vein.

8. That each party has mined the orebodies of the other in the claims involved.

Therefore the court concludes:

1. That plaintiff owns all orebodies in the Rainbow vein between the Elm Orlu west end-line and a parallel line projected from where the south wall apex of said vein crosses the common side-line, or about 980 ft. of said vein.

2. That defendant owns all orebodies in the Rainbow vein between the projected Elm Orlu end-line at the south wall apex crossing of the common side-line by said vein and the east end-line of the Black Rock claim, or about 1200 ft. of said vein.

3. That plaintiff owns all orebodies in the Pyle strand from its divergence at its west end from the Rainbow vein in the Elm Orlu claim easterly as far as the apex of said strand is within said claim and between Elm Orlu end-lines projected, and defendant owns all thereof east of the projected end-line last aforesaid.

4. That defendant owns all orebodies in the Jersey blue vein between the points where the apex departs from defendant's premises across end-lines as laid or projected, throughout depth, save at its intersection or crossing of the Rainbow vein between Elm Orlu end-lines as laid and projected.

4-2. That plaintiff owns all orebodies in the Creden vein from its divergence at its east end from the Rainbow vein westerly as far as the Creden apex is within the Elm Orlu claim, between Elm Orlu end-lines there projected, and defendant owns all thereof west of the projected west end-line last aforesaid.

5. That accounting in damages be had.

6. That each party pay its own costs, and the decision herein is made a part hereof. An appropriate decree will be entered.

The Anaconda company has taken a three-year bond on the Douglas mine in the Pine Creek district of the Coeur d'Alene, 15 miles from Kellogg. An initial payment of $1000 has been made and $10,000 is due in nine months, after that $50,000 will be paid every six months until a total of $361,000 has been paid. The new owner will also pay a royalty of $3 per ton of ore mined, the royalties to apply on the purchase price. The ore is a complex, containing 17% zinc and 6% lead. Previous efforts to treat the ore were not successful. Flotation failed to make a good separation because the sulphides are intimately mixed, and even fine-grinding will not put the ore in such a condition that the zinc and lead can be floated separately. The Anaconda company proposes to leach it with sulphuric acid and precipitate electrolytically at its new plant at Great Falls.

A mill will be erected at the mine to give the ore a rough concentration. The concentrate will have to be hauled 15 miles to the railroad, auto-trucks will probably be used for this purpose. The Douglas had 40,000 tons of ore blocked out for years, but nothing could be done with the property because of metallurgical difficulties. There are several other mines that will be able to operate at a profit when the company is ready to accept shipments of zinc ore. Heretofore a small miner has been unable to sell his product because the smelters usually insist on a 50% zinc content, and there is no custom mill to which he could send his ore for concentration. The company expects to have its zinc plant in operation this year, and will no doubt accept shipments at its sampler in Butte.

During December the Butte & Superior company produced 16,031,000 lb. zinc in concentrate from 50,500 tons of ore. The recovery was the highest, namely, 95.77%. Re-treatment of tailing is now under way, increasing the yield.

MEXICO CITY, MEXICO

THE SITUATION IN MEXICO.—THE FUTURE.

The political situation, which is of secondary interest to American miners, is still the all-absorbing topic in Mexico, as it has been since 1911. After the circulation among the Mexican chiefs, in July, 1915, of the invitation to the peace convention of the A.B.C. conference, it was thought here that the United States government had at last awakened to its duty, and was about to undertake the pacification of Mexico. What was the surprise in September at the announcement of the recognition of Carranza, the contestant who had not only refused to attend the proposed peace convention, but had repudiated the right of any foreign power to interfere in Mexico, no matter whose rights were being violated. Perhaps the failure of the plans for the convention might have been expected when the United States invited the A.B.C. powers to sit on the case of Mexico, a country in which none of them had either investments or resident citizens, and whose coercion would set a dangerous precedent in the event of their own future misbehavior. Though the Carranza faction had become

MAP OF MEXICO.

the strongest and best-behaved of the Mexican contestants, its recognition offers little hope for the speedy restoration of normal conditions. There are too many obstacles, among which may be mentioned: inflated currency, famine, pestilence, race prejudice, railroad and bank paralysis, Zapatism, and Syndicalism.

Inflated currency takes its place as the most serious obstacle to the alleviation of Mexico's economic woes. The decline in value of the legal-tender or paper peso from 30 cents in July 1914 to 6 cents in July 1915, was a heavy blow to the middle class, as it practically ruined everyone whose fortune was in money, such as loans, mortgages, bank credits, or currency. The fall completely upset the labor market, and caused misery and starvation to thousands of laborers' families, whose wages, advanced much slower than the decline in the purchasing power of money. Importation of clothing, drugs, and hardware, for which Mexico depends on the United States and Europe, has almost ceased, while the equipment of new mines or factories with foreign machinery would now be impossible, except by companies financed from abroad.

The famine, caused last spring by the wholesale exportation of food in exchange for guns and cartridges, was little alleviated by the autumn harvest, which was far below normal in quantity, because of lack of field hands and of seasonal rains. The natural scarcity has all along been aggravated by the diversion of the railroad rolling-stock for fighting purposes, and by the extortions of the military leader who in many cases refused to pass food trains until paid huge sums as toll.

Starvation in Mexico City was killing its daily hundreds in July under the Zapatista regime, and though food became a little more plentiful when the Carranzistas entered in August, the persistent famine soon brought on an epidemic of typhus of which there are now said to be 50,000 cases in the capital alone without including the epidemics at Puebla and various other cities. As an indication of the sincerity of the revolutionary humane professions, it may be mentioned that Carranza refuses to admit the U. S. Red Cross society into Mexico for the relief of its famine and pestilence.

The anti-foreign group was quite influential in the Madero regime, and its first great victory was the dismissal of all the engineers and conductors on the National railways in the summer of 1912. But the rapid physical decline of the railroads did not begin until the discharge of all the American superintendents and master mechanics on the seizure of Vera Cruz in 1914. The final collapse of regular train service came with the 'intervention' of the English-owned 'Mexicano' railway by the Carranza government a year ago, and the wholesale destruction of rolling-stock and stations by the Zapatistas during 1915. At present the railways are entirely in the hands of Mexicans, and are conducted as might be expected in a country where the working-classes have no education and the educated classes are too proud to work. At present the shipment of freight has almost ceased, and even charcoal fuel has risen to unheard-of prices.

In the autumn of 1914 the banks first refused to sell drafts on other cities; in early 1915 they stopped receiving new deposits, and later in the year they refused to receive even their own checks for deposit. Since the express companies and post-office suspended the shipment of paper money or the precious metals a year ago, the only practical way to now ship such articles is by private messenger. To add to the monetary chaos the Federal treasury has just declared void the charters of most of the great banks.

The Zapatista faction, which has functioned since 1910 as a medley of reform, reaction, and rapine, has recently thrown aside the first 'R' and devoted itself mostly to the last. The plan of Ayala, which declares for the division of the great estates among the peons, has finally resulted in the concentration of the 26 former estates of Morelos into four, and these principalities are the personal property of Emiliano Zapata and three of his friends, who rule as despotically and ruthlessly as ever did Persian satraps.

Always the worst disciplined of the revolutionary armies, the Zapatistas have now thrown off the little restraint they showed during their short alliance last year with the Villistas. Besides their destruction of railroad property and the looting of defenseless villages, they have ruined scores of factories and mines. Sometimes they wreck for profit, as when they destroy vacuum-pans and alcohol-stills in order to separate the copper as junk; often they smash from sheer wantoness, as when they blow up a hoist with dynamite or sprag the fly-wheel of a moving Corliss engine with a log. As Zapatism has long made mining impossible in most of the rural districts of southern Mexico, so the rise of Syndicalism may soon hamstring production of all kinds in even such hitherto-favored cities as Pachuca. Actively preached in Mexico since 1910, the missionary centres for the Syndicalist propaganda have been located at Barcelona, Spain; Paris, France; and Los Angeles, California. In the summer of 1914, when the Carranzistas first entered Mexico City, the local Syndicalists, called the 'Casa del Obrero Mundial' were given a centrally located convent for their meetings, and in February, 1915, when General Obregon re-captured the capital, they numbered 25,000 local members. By the help of the clever Dr. Atl, Obregon was able to cajole the Syndicalist leaders into a public support of Carranza, and the first fruits of this operation was the enlistment of 5000 of their followers in the ranks of his army.

The leaders themselves, who were orators, were then organized into the 'Revolutionary Committee' and have since been actively engaged, at Government expense, in preaching the Syndicalist doctrines among the workmen of the cities. The I. W. W. is the United States branch of Syndicalism, and its plan for Mexico was published as early as 1911 in its Los Angeles paper *Regeneracion*. This plan is as simple as it is bold and merely involves the confiscation of all the productive property in Mexico by the peons, and its future administration by a communistic Syndicalist commission.

The method of the proposed confiscation was not explained in *Regeneracion*, but evidently an effective scheme would be to make the operation of their properties so unprofitable for present owners that they would be forced to shut down, and then the properties could be 'intervened' by the Government and presented to the Syndicalists. How far the latter now control the Government policy it is difficult to state, but the inflation of the currency, the minimum wage and 8-hour laws for labor, the maximum price law for commodities, the laws forcing employers to provide free schools and homes for their laborers, etc., are all steps toward realizing the plan of *Regeneracion*.

It may not be generally known that Syndicalism is not merely an integration of 'syndicates' or industrial unions for economic betterment, but is basically a revolutionary political movement founded on the maxim of Proudhon "all property is robbery," and on the program of Bakemin, "all existing institutions must be destroyed." It rejects all prevailing ethical standards, dubbing them "slave morality," only tolerates employees until they can be despoiled, and advocates "direct action" which menaces employers with sabotage and society with the general strike. Anyone familiar with the ignorance of the Mexican masses and the dishonesty, disloyalty, and viciousness of large sections of the workmen must view with the direst foreboding the preaching of the destructive doctrines of Syndicalism. If mining operations have been difficult in the past on account of the degraded labor, what can be done when the same miners are taught to regard their employer as their natural enemy, and are waiting only for a good chance in order to dispossess him entirely?

Of interest to mining men is the plight of Oaxaca. Declaring itself sovereign last April, this State seceded from Carranza's rule, and ever since has been cut off from the outside world, for Carranza controls the seaports and the only exit to the north, the Southern railway. On its withdrawal Oaxaca issued its own paper money and organized a State army of 4000 men under the direction of Higinio Aguilar, Mezquicro, and various ex-Federal officers. The secession did not save Oaxaca from the prevailing famine, and it is now suffering, too, from the typhus epidemic. Mining is paralyzed completely, as there is now no way of exporting either mineral or bullion.

The existing woes of Mexico are really all results of the same cause, the attempt to super-impose modern industrialism upon a barbarous and medieval population and government. Not only is the bulk (80%) of the population illiterate, but it is almost identical in race and customs with the Aztec barbarians as first discovered by Europeans. Of the educated class the majority are Spaniards or Spanish *mestizos* and these are medieval in sentiment, consider work degrading, and treated the peons of the ranches and the free Indians of the communal villages so badly during the last 30 years as to bring on the present revolution. As a rule the American and English owners of the mines and railroads treated their peons liberally, but their fair-dealing was unable to prevent the catastrophe in the face of the Spanish slave-drivers and the scandalously-corrupt and oppressive government of Porfirio Diaz.

If one will survey the earth, he will discover that there are few countries where much outside capital has been invested, except in civilized nations or their colonies. Why Mexico was made an exception and succeeded in attracting a billion dollars from the United States, and as much more from Europe, between 1880 and 1910, is one of the mysteries of financial history. The Chinese are far more civilized than the Mexicans,

yet they have secured scarcely a tithe of the foreign capital obtained by Mexico, even though they harbor ex-territorial courts for its protection. The only parallel to Mexico, as a beneficiary of foreign capital, is Argentina, but its population is almost exclusively of the white race and contains more of Italians than Spaniards.

Can Mexico develop a native government sufficiently competent and honest to quell the existing anarchy and satisfy the just claims of foreigners for indemnity and future protection? Though prophesy may be rash, the outlook now indicates a negative answer. It is not a question of *form* of government—the heterogeneous and ignorant populace can only be ruled from above—but of its personnel. It is certain that no colonial power, except possibly Spain, would have given Mexico as a colony as bad a government, viewed either from the standpoint of civilization or of justice to the proletariat, as she has almost continuously had to endure for the past century under her native tyrants satirically called 'presidents.' From Iturbide and Santa Anna to Diaz and Huerta, Mexico has had a list of oppressors whose crimes might make even Abdul Hamid blush. The propping of these despotic thrones by the ostensibly democratic Monroe doctrine has been one of the *queerest* anomalies of history.

LORDSBURG, NEW MEXICO

Burro Mountain, Hanover, Carpenter, Mogollon, Organ, Steeplerock, and Lordsburg Districts' Developments in Copper, Zinc, Silver, and Tungsten.

Mining activity in New Mexico has shown no exceptionally visible increase during the past quarter, save for the opening of several copper properties, the operation of which has been warranted by the high price of copper.

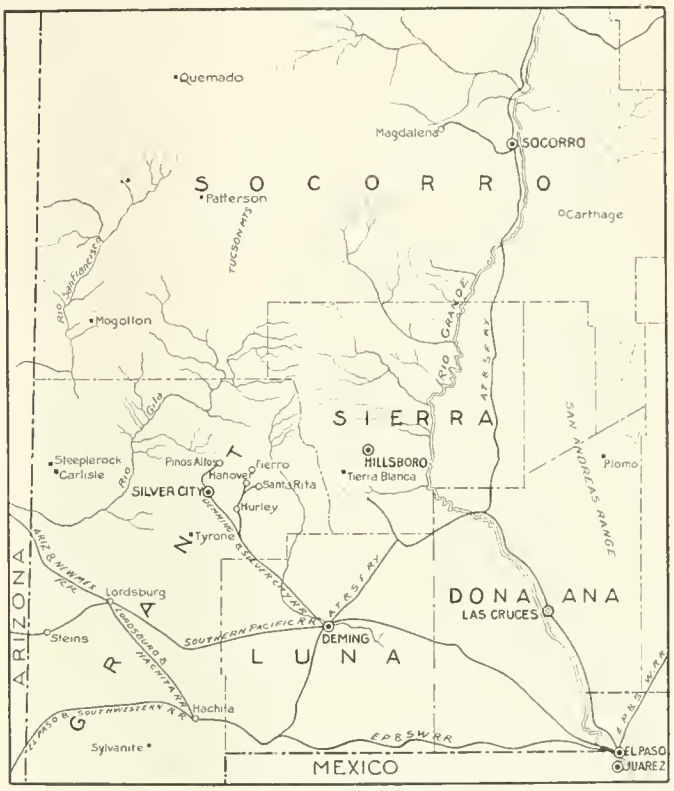
Chino continues with renewed vigor. At Tyrone the Burro Mountain Copper Co. proceeds with its work preliminary to beginning production by the middle of the year. At the company's mill-site all preparations are completed for the opening of the new 1000-ton mill. It is possible that by April 15 this plant will be treating ore from the mines five miles west of the mill. The Thomas Parker hospital is completed and nearby work is being expedited on the erection of brick houses for employees. The houses will rent for $4 per room per month. Development is being carried on in the mines, and additional units have been ordered for the Deisel engine generating plant near the Niagara haulage-adit. Tyrone has not advanced in any noticeable manner within a year's time, but with the coming spring it is stated that the management will put on additional forces, and soon improve things. It has been reported that the company has purchased the holdings of the Savanna Copper Co. for $700,000, but further verification of this rumor has not been given out. The Savanna company owns 150 claims, or 2557 acres of ground in the Burro Mountain district, among which is some very valuable mineral ground.

At Hanover the Empire Zinc Co. is preparing for the operation of its electro-static zinc-ore concentrating plant. A Snow-Deisel engine has been installed at the Empire power-house, and the electric generating plant put in operating order. Ores from the Thunderbolt property will be milled together with some custom ore. Work at the Nason adit and the zinc carbonate claims will continue as heretofore. Mining of zinc ores is being done by the Republic Mining & Milling Co. on the Welsh property. Hotchkiss and Gilchrist are also doing some mining in the Hanover area. At Fierro the Colorado Fuel & Iron Co. is shipping from 10 to 12 carloads of magnetic iron ore daily from the Snow Flake and Jim Fair open-cuts.

Owens Bros. of Santa Rita are doing extensive development at the Grand Central mine in the Carpenter district. It is their intention to erect a concentrating plant near the mine. Visitors to the Grand Central report that the operators are blocking out immense bodies of high-grade zinc sulphide ore.

Stimulated by the high price of silver, work in the Mogollon district is being extended, and it is reported that there has been a resumption of operations at the Deadwood mill and also the Alberta mine. Road work from Magdalena to the Mogollons is progressing rapidly, and before many months an excellent road will have been constructed into the camp, eliminating Silver City and Gila from the route.

In the Organ district of Dona Ana county the Black Prince zinc mine has been bonded to William T. Swoyer, who will begin work at once. General Dunwoody, owner of the Oregon mines in the same district, is supervising the installation of



PART OF NEW MEXICO.

mining machinery, and will again operate the mines south of the Modoc claims.

The Calumet & New Mexico Co. at Phillipsburg is doing development under the management of U. G. Wolfe.

The White Oaks Mines Consolidated is mining, milling, and shipping tungsten ore from the old Abe property. Five tons of concentrate was recently shipped by the company.

Activity in the Steeplerock district of southern Grant county, has taken a new lease on life with the new year. Manager Duvall of the Carlisle mine has begun unwatering the shaft, and has opened workings to a depth of 300 ft. below water-level, revealing commercial ore in good quantity. A sale has been made of property adjoining the Utter mines, and much patenting is going on throughout the district.

Heavy shipments of silicious copper, gold, and silver ores are being made from Lordsburg. Wells and Sholly are leasing the No. 2 property of the Bonney Mining Co. and have received encouraging smelter returns. The Silver City and Santa Rita people who took over the Bonney mine are pushing development, and are getting the mine in condition for operation. The 85 Mining Co. is shipping over 400 tons of ore daily to smelters in Douglas, Hayden, and El Paso. Electric haulage is proposed for the mine. Spence and Huntington are extracting an excellent grade of ore on the Nevada lease from the 85 company. Ore is being shipped from the Nellie Bly, and also the Robert E. Lee mines in the Leidendorf part of the Lordsburg district.

SILVER CITY, NEW MEXICO

NOTES ON THE PINOS ALTOS DISTRICT MINES AND MILLS

The possibilities of the Pinos Altos district are considerable, and in addition to the properties described below there is an extensive grano-diorite deposit, intersected by shoots of high-grade copper-silver ore from which shipments have been made.

The Cleveland mine of the Empire Zinc Co. is situated on the south side of the mountain, from which a fine view is had of the country south, including Silver City.

The company evidently has great faith in its zinc deposit, judging from the substantial buildings erected for its employees, including change-room and mess-house. In the mine and mill 100 men are employed, they are well satisfied with their treatment.

The zinc ore contains some gold, copper, and iron. It is mined from a 900-ft. adit. The output is 100 tons per day.

The mill is well constructed and equipped with the latest machinery for separating a complex ore. Eight magnetic separators produce a different size concentrate. Tailing is being conserved, and probably the company will install a flotation-plant before long, saving from 10 to 12% more of the metal than at present. The company also has large holdings in the Hanover district, and is completing a mill there similar to the Cleveland plant.

The Pinos Altos Mining & Milling Co.'s plant, known as the Wright and Stauber mill, is two miles south-west from Pinos Altos. The mill and mine are both working, employing about 50 men. The company has 18 claims under lease and bond from the Savannah Copper Co., extending into the town; all produce good ore. At present, and for some time past, the company has been working on the Pacific No. 2 or the Skillacorn vein, belonging to the Pacific group. The holdings were secured two years ago. During this time it is reported that the output was $125,000 of ore. The ore is complex, and contains copper, gold silver, lead, and zinc. Some rich gold ore has been taken from shoots near the surface to 200 ft. depth. Water conditions are reported to have prevented further working, but the company expects to deal with this effectively soon, when sinking on the high-grade will be resumed. The company will shortly begin work on the Gillette shaft, within a short distance of the mill, which is now down 900 ft. This company's mill is the only one of its kind in the south-west using the Huff electro-static machine. From the Wilfley tables the product is dried and then elevated to a series of screens. Each size is deposited in a steel storage-tank, from which it is piped to the two Huff machines. These deal with their respective size concentrate. They occupy a space of 10 ft. wide by 14 ft. high. Two products are made, namely, copper and iron, containing gold and silver, which go direct to a shipping bin; and zinc, barite, manganese, and waste. The latter goes to a wooden vat, and is thoroughly wetted with an 0.5% copper sulphate solution. In this solution a thin film of copper sulphide is precipitated on the zinc sulphide only. This makes the zinc particle an electric conductor. This concentrate is again put through the drier, the sizing-screens, and the Huff machine, the zinc being coated with the copper sulphide being pulled away by the current as it slides over the 'toboggans.' This gives a high-grade zinc concentrate, which is sent direct to a separate shipping bin. The tailing is conserved for future treatment, probably flotation. There are three bins of concentrates: first, lead with gold and silver, which comes direct from the second series of Wilfley tables, worth $60 per ton; second, a copper-iron, worth $60 per ton; and third, zinc concentrate, valued at $50 per ton. The final recovery is from 60 to 65% of the original value of the ore. Shipments of concentrates total one car of lead, one of zinc, and two of copper each month. All but the zinc is shipped to El Paso, this going to Altoona, Kansas.

The Langston company, which owns an interest in the mill, and whose property adjoins that of the Stauber and Wright, recently concentrated its ore, and made a shipment of 90 tons of zinc, 10 tons of lead, and 50 tons of copper concentrates.

Oscar Long and J. E. Trotter, practical concentrator and flotation men, at present at Hurley, are contemplating taking over the old Mammoth mill at Pinos Altos, their intention being to operate it as a custom plant. This is good news and will mean much to the small mine owner in that district. They have tested the ores of the district and consider them amenable to flotation, but they will also install an electro-static machine. A recovery of 95% is possible. The mill will be equipped to treat 200 tons per day. The transaction may be consummated within the next 60 days.

J. A. Michaels, of the firm of Hyman-Michaels Co., of Chicago, arrived in Silver City on January 7. He is here to load and ship the old narrow-gauge railroad equipment of the Silver City, Pinos Altos & Mogollon Railroad Co., which eight years ago operated between Silver City and Pinos Altos. There are about 30 carloads of material, besides locomotives, cars, etc. The line was operated only a few months when the owners, the Comanche Mining & Smelting Co., went into bankruptcy. The smelter and the mining properties were taken over by the Savannah Copper Co. This was about eight years ago. Three years ago the Hyman-Michaels Co. took over the railroad equipment.

WASHINGTON, D. C.

NOTES ON THE LEASING BILL.

The bill authorizing the exploration for and disposition in the public domain of coal, oil, phosphate, gas, potassium or sodium, commonly known as the Leasing Bill, and which is not a little disapproved of in the West, where it effects the public domain, has passed the House of Representatives, and is now in the Senate where it has been sent to the Committee on public lands. The passage of the measure in the House took only a few days, and while thoroughly discussed and dissented from by Western members, it had such large support that it was deemed not even necessary to have a roll-call on the bill. It is expected that the bill will meet with more vigorous opposition in the Senate, which was the case last year when the bill was up and prevented from passing; but it remains to be seen if the bill can this year find so convenient a jam of legislation as happened last winter. The bill is one of the conservation measures before Congress. If it ever reaches the President it will be signed by him. The measure does not effect metal mining, but it is feared it may set a precedent thereto. In its general provisions as to coal it imposes a minimum royalty of two cents a ton, the Department of the Interior to adjust each lease according to conditions that are present. To insure development a rental of at least 25c. per acre will be required for the first year, and 50c. for the second, third, fourth, and fifth years, and $1 thereafter during the life of the lease, except that the rental for any year shall be credited against the royalties as they accrue for that year. Railroads may acquire leases, but only for the production of coal for their own use. In the oil and gas sections of the bill the Secretary of the Interior is authorized to issue a prospector's permit for two years, and if any prospector discovers oil he may secure a patent to one-fourth of the area of the prospector's limit. No well shall be drilled within 200 ft. of the exterior boundaries of the lease when adjacent lands are in The Government lease or in complete government ownership. Rentals and royalties are to be charged. Mining of phosphates by means of leases is to be through competitive bidding or by other regulations. General provisions on the bill forbid any person, association, or corporation from holding more than one lease of each of the classes of deposits named in the bill, nor shall any corporation hold any interest as a stockholder of another corporation in more than one lease, nor can any stockholder in a corporation acquire interests in leases beyond the maximum fixed.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Cordova

Ore has been cut by the main cross-cut at 700 ft. in the Kennecott company's Jumbo mine. In the Bonanza a new shoot has been opened at 600 feet.

Juneau

The Alaska Gold Mines Co. is to issue $1,500,000 6% debentures, convertible into stock at $30 per share at any time. The debentures are to be known as 'series B,' callable at 110 after three years from date of bonds, March 1, 1916. The directors state that the issue is necessary to complete mine developments, mill and power construction, etc. D. C. Jackling, on January 12 prepared a brief outline of results in 1915, most of which has been published in this journal.

ARIZONA

Heavy rain and snowstorms have considerably hampered mining and treatment operations in this State during the past week or more.

Cochise County

The daily ore output of the Calumet & Arizona is 3000 tons, producing 260,000 lb. of copper. The roof of the flue-dust chamber from the roasting plant is being repaired without stoppage.

Gila County

In December the Old Dominion produced 2,495,000 lb. of copper. On February 1 a further extension of the sliding-scale for wages at this property will become effective; also by the Miami and Inspiration companies. The latest is based on copper from 22 to 25c. per pound. All classes of labor share in the advance. Miners receiving $4.40 per shift on 20-cent copper will get $4.50 on 21c., $4.65 on 22c., $4.75 on 23c., $4.90 on 24c., and $5 on 25-cent.

At the Inspiration mill 14 of the 18 units are in operation, with a capacity of 10,000 tons per day. Nine units in December produced 6,000,000 lb. of copper.

Greenlee County

On January 24 the strikers at Clifton, Metcalf, and Morenci, voted to return to work under the offer made by the managers of the Arizona, Detroit, and Shannon companies on the 8th. A sliding-scale of wages is to be in force, but no union is to be recognized.

Mohave County

(Special Correspondence.)—There are about 100 companies in the Oatman-Kingman district either developing properties or rushing equipment for extensive development. The companies that are most advanced in their work are the Black Range, Boundary Cone, Gold Ore, Carter, United Western, Oatman Gold Mining & Milling, Big Jim, and Ivanhoe. Through their work the proving of a number of the principal vein systems is approaching an interesting stage, and within the next four months this work should verify how correct are the theories relative to the district which have been advanced by a number of prominent mining engineers and geologists. In fact, the Oatman district seems at this time to be entering the most interesting epoch of its history.

Oatman, January 18.

The following remarks were made by Charles E. Knox of Tonopah, Nevada:

"Oatman will in a short time be known as the greatest gold camp in America. Oatman has five well-marked ore zones. There are three mines in the Tom Reed zone, namely, the United Eastern, Tom Reed, and Big Jim. The Big Jim with a 46-ft. vein of good-grade ore now leaves the prospect class and takes its place in the mining column. The owners of the Big Jim may well feel gratified at the remarkable showing and the accuracy with which this work was projected to make this development. Superintendent Keating is to be congratulated not only upon the realization of his geological theories, but the accomplishment of such a great piece of work in such a remarkably short time. I am told that work was started in July, since which time the property has been equipped, the shaft sunk 400 ft., and the cross-cut driven to and through the vein for a distance of 205 ft. This demonstrates that mining conditions in this part are most favorable for cheap and efficient work. I have been shown a number of other very promising properties in the district, some of which have excellent showings even for the small amount of work done at the present time. The best surface showing that I have seen in this, and I might add in any district, is the Times property, some distance north-west from the United Eastern. This property, with a 30-ft. vein, shows at the present time a body of ore for 50 ft. in length, all of a high grade milling character, and in places several feet, the value of which approaches the sensational. Never have I seen better preparations for prospecting and development in a new camp. Fully 25 properties have been well equipped or have that equipment in transit, with well-supplied treasnries which ensure thorough development and will undonbtedly in the near futnre result in the discovery of other United Easterns and Big Jims. There is every evidence that the East, particularly New York, is becoming deeply interested in Oatman."

The Cerbat Range region, north of Kingman and extending beyond Chloride, has been a great metal producer, and is still considered to have splendid prospects. The previous principal output was silver, but now copper and zinc are being produced; some of the mines being the Copperfield Porphyry, Tennessee, Golconda, Golconda Extension, Payroll, and Rainbow.

Pima County

The New Cornelia Copper Co.'s railroad was completed on January 18. Regular service from Gila Bend to Cornelia will commence in two weeks.

CALIFORNIA

Operations in the oilfields as reported to the State Mining Bureau during the week ending January 15 show a sharp falling-off in the number of new wells proposed. There were only five reported as against nearly a dozen each week for the last two months. Other work such as deepening or re-drilling wells was also slightly below the average, but as these are more in the line of routine matters affecting the upkeep of a property less attention is attracted by them. Recent damage by storms will retard production for a few weeks in some of the fields. The work of testing water shut-off, which is carried on directly under the inspection of the Bureau engineers, maintains its usual volume. The importance of inspection is now very generally recognized by operators and the Bureau is taking steps

to maintain its standards of thoroughness in this matter without giving the entire time of its engineers to that branch of the work. The most important work that the Oil Department of the Bureau has undertaken is the study of underground conditions leading to recommendations as to what sands should be developed and what formations may be properly left exposed to water. Lack of uniformity of depths at which various wells have been protected by casing has in the past been a greater cause of damage than has poor workmanship on the part of drilling and cementing crews.

Amador County

The old Zeila mine at Jackson is being re-opened by the Kennedy company. A new shaft is being sunk. The Kennedy mine shaft is 3900 ft. deep vertical; it is to sink to 4100 ft. where the two principal veins are expected to junction. The 10-stamp mill continues steady work.

The Argonaut incline shaft is down nearly 1600 ft. The monthly output is around $60,000.

The South Eureka continues its development in the Oneida mine. Good ore is being mined from 3200 ft. in the Central Eureka.

Colusa County

Owing to the high price of quicksilver it is probable that the old mines near Sulphur creek will be re-opened. J. W. Cuthbert of Willow Springs is interested in some property there.

El Dorado County

(Special Correspondence.)—A 3½-ft. vein of 'ribbon-rock' quartz assaying $44 per ton has been opened at a depth of 130 ft. in the Teddy-Bear claim, situated on the Mother Lode between the old Church-Union and the Lava Padre gold mines. The vein was cut last week while sinking a winze next to the hanging wall in the bottom of a cross-cut adit about 240 ft. in from the portal. Alden D. Fraser, manager for John W. Cover, of Seattle, was present watching sinking operations. The Teddy-Bear property, which was acquired by Mr. Cover about three weeks ago, consists of the Teddy-Bear, St. Croix, Hotspur, Hotspur-Extension, and the Oidinna, situated about five miles south of El Dorado railroad station. Mr. Fraser states that deep-level development will be pushed in a modern manner.

Placerville, January 15.

Kern County

At a meeting of the directorate of the Yellow Aster Mining & Milling Co., held at Los Angeles on January 21, E. D. Mooers, second vice-president was elected first vice-president, to succeed C. G. A. M. de Pauw, who has ceased to be connected with the concern in an official capacity. Mr. Mooers is the son of the original locator of the Yellow Aster mine, and has had many years experience in the mining business. The officials are as follows: Albert Ancker, president; E. D. Mooers, vice-president; R. L. Burcham, secretary; Carl H. Fry, superintendent; W. J. Cotton, managing director; and Ward Chapman, attorney.

Nevada County

(Special Correspondence.)—The Mineral Hill mining district is experiencing a good revival as the result of work done during the past two years by the Queen Regent Merger Mines Co. of San Francisco. The company has contracted for a complete treatment-plant to be in full operation by February 15, to treat its ore at the mine at $3.50 per ton. A percentage of profits applies on the purchase price until the plant is paid for in full, after which it will be taken over and operated by the Queen Regent company. The engineer for the parties interested in the deal reports sufficient high-grade ore developed to pay for the plant in 90 days, as the ore averages $50 per ton in copper, gold, and silver. The activity of the company has aroused much interest in the district, and properties have changed hands on which active development will be started at once.

Spenceryille, January 15.

The new 5-stamp mill of the Ben Franklin mine will soon be finished. C. J. Bryant is to be in charge. New York people own the property, and are also developing the Alaska adjoining. J. L. Claghorn is representative.

Sacramento County

At Natoma the Natomas Company of California has constructed a dredge for leveling and re-soiling the tailing. This is done by means of a double stacker; one for boulders and gravel, the other for soil. The boat is 100 ft. long, 56 ft. wide, and 12 ft. deep. The buckets are of 15-cu. ft. capacity, and will dig to a depth of 35 feet.

San Diego County

Bulletin 620-P of the U. S. Geological Survey, by Waldemar T. Schaller, discusses cassiterite in this county. The tin-bearing area is in an arid region. The claim-owners are R. Carson, T. L. Harvey, and D. H. A. Fiske, of Pasadena; they hope to

Index map showing position of cassiterite locality in San Diego county. The rectangle indicates the gem tourmaline field of southern California, throughout which are found pegmatite dikes similar to the one described in the bulletin.

do some more work this year. The handful of crystals found in the spring of 1915 was extracted from a single pocket in a flat-lying pegmatitie dike, and an examination has failed to offer any hope of finding more in large quantities, although the quantity found exceeds all the occurrences of tin ore in place previously known in the county.

Shasta County

(Special Correspondence.)—Mining on the east side of the copper district is fairly active. The drift from the lower adit at the Shasta Belmont has entered promising ore, and is expected to soon cut the vein that yielded rich ore near surface. The adit is being extended 100 ft. The management expects to start shipments in the spring. William Arps is supervising work. The property lies near Copper City.——The Greenhorn, near Tower House, is undergoing vigorous developments, with M. E. Dittmar manager. Driving of the main adit is proceeding quickly to open promising ground beyond the main workings. A good deal of ore is blocked out, and it is probable a concentrating plant will be erected next summer.——C. L. Wilson and associates are working the Arps property, a short distance from the Shasta Belmont. Ore containing copper and manganese has been opened, and development of the lower copper deposits will be done as soon as weather conditions improve. Numerous prospects in this part will be worked next summer, according to owner's statements.

It is rumored the Bully Hill Copper Co. has definitely decided on the building of a zinc smelter near Copper City, and that an offer has been made to the Afterthought Copper Co. with a view to treatment of Afterthought ores at the

plant. The Afterthought mine is near Ingot, and contains large reserves of copper-zinc ore. The company has been contemplating installation of a concentrating plant.

Driving of No. 6 adit is progressing steadily at the Mammoth mine, near Kennett. Production of zinc ore at the rate of $80,000 to $90,000 per month continues, and a large quantity is exposed. The Kennett smelter is producing over 1,600,000 lb. of copper per month, including the ore smelted for the Balaklala company.

The vein recently encountered on the 1300-ft. level of the Gladstone mine, at French Gulch, is said to be developing well. The 30-stamp mill is running steadily, and a normal force is employed. Development of much new ground is proceeding. E. Young is superintendent.

Redding, January 24.

According to F. H. Dakin, Jr., the Virginia Mining Co., which owns the Uncle Sam mine, has 10 stamps working, and proposes to install a tube or ball-mill of large capacity, also probably a Deister slime-table and a flotation plant.

Sierra County

The annual meeting of the Tightner company was held at Grass Valley on January 22. No details of results are available, but prospects for continued large profits are good.

Trinity County

The Alta Bert Dredging Co.'s property near Trinity Center has been acquired by the Trinity Development Co. A large dredge may probably be constructed. Other dredging companies along the Trinity river are meeting with good results.

Yuba County

At Hammonton and Marigold the Yuba Consolidated Gold Fields Co. is constructing a dredge at each place, employing about 125 men on each, resulting in considerable activity.

COLORADO

People who have never wintered in the Rocky Mountains often wonder why some mines suspend operations when winter comes, according to *The Daily Mining Record*. Shareholders in some of these mines are inclined to criticise such action on the assumption that a mine should operate during all seasons. A winter spent in the mountains by these critics would materially change their views. There is no more bleak, lonely and forbidding site than is occupied by the mine, far up in the mountains, that is remote from a town or railway-station. With the thermometer often registering as low as 40° F. below zero, while the narrow roads are hidden under great masses of snow, the transportation of ore becomes impossible. The mine is completely snowed in pending the arrival of spring, and man is helpless to alter the conditions. The occasional miner who ventures from the camp on snow-shoes risks his life, although slow to concede the fact. Like many of his kind in the past he may fall a victim to avalanches or snow-slides. Even the mine buildings, in some places, are in danger from this source, as the record of mining disasters bears testimony. Bitter cold, danger, and storms ever surround those who do whatever they can at the mine. It is safer to affirm that any unacclimated Easterner who managed to survive a winter amid such surroundings would acquire an added respect for the miner and fully comprehend why some mines are not operated in the icy winter months.

Clear Creek County

The Hudson mill, using flotation, is at full capacity, treating 80 tons per day, yielding 20 tons of concentrate.——The Newton mill is treating up to 100 tons per day, producing 20 tons of $30 concentrate.

Lake County (Leadville)

Progress at the Anderson adit into Prospect mountain is reported to be good, the face being in 1400 ft., in fairly hard ground. Machine-drills are employed.

Within two months the Fortune mine will be producing 1500 tons of carbonate of zinc and gold-silver sulphide ore. A good tonnage is ready for extraction.——High-grade zinc carbonate is being shipped from the Ruby in the Weston Pass district. ——The Matchless on Fryer hill is sending 16% carbonate to the Western Zinc Oxide plant, which is improving its metallurgical results.

A storm in the Lackawanna district interfered with work at the Mt. Champion; the aerial tram was damaged somewhat.

On January 18 a great snowslide from Mt. Elbert in Lake county, on mile above Twin Lakes, killed two men, and did $50,000 damage to the Gordon mine.

San Juan County

According to F. C. Gilbert, manager of the A. S. & R. smelter at Durango, in a letter to the *Silverton Weekly Miner*, San Juan, San Miguel, La Plata, and Dolores county mines sent the following ore to the plant; an increase in quantity, but practically the same value:

County.	Tons.	Value.
San Juan	19,672	$915,523
San Miguel	25,577	1,398,696
La Plata	3,041	92,213
Dolores	13,169	241,211
Total	61,459	$2,647,643

This smelter is favorably situated to receive ore from La Plata, Ophir, Red Mountain, Rico, Silverton, and Telluride.

San Miguel County

A violent storm in the Telluride district last week did an immense amount of damage to mining, power, and railroad companies, especially the Camp Bird, Tomboy, Smuggler-Union, Liberty Bell, Black Bear, Western Colorado Power, and Rio Grande Southern.

Teller County (Cripple Creek)

(Special Correspondence.)—On January 13 a new water-course was cut by the Cripple Creek deep-drainage Tunnel in Elkton ground, not far from the point where the Elkton shaft will connect with the Tunnel when the shaft has been sunk to that level. This resulted in a large increase in the flow of water, equal according to T. R. Countryman, to 2300 gal., making the flow from the portal at the present time about 14,630 gal. per minute. Just previous to cutting the last water-course a strong vein was intersected at a place about 250 ft. from a point directly under the Elkton shaft. This vein was reported to be seven feet wide. Where cut, vein matter was too poor to make it profitable to explore it at present. Later on, however, its development may open ore of commercial grade.

Victor, January 19.

A joint shipment of ore was made over the Short Line to Colorado Springs under armed guard last week by the Cresson, Portland, and Vindicator companies; the total was 175 tons, namely, 50, 25, and 100 tons respectively, averaging $1430 per ton.

IDAHO

Shoshone County (Coeur d'Alene)

In spite of bad weather prospecting for tungsten ores is being done in old placer ground near Murray. Several developments are reported.

The National copper mine and mill are employing 50 men. Working a trifle over one shift daily the plant is producing four cars of concentrate per month. The product realizes $90 per ton. Silver is increasing with depth in the mine. The company has acquired 90% of the Homestake company's stock, adjacent property.

Ore production of the Pine Creek area increases, and a railway is badly needed. If the steam roads do not make an effort, the mine-owners may endeavor to have an electric line constructed. Antimony, lead, and zinc ores are produced.

ILLINOIS

Jo Daviess County

(Special Correspondence.)—At Day Siding the Wisconsin Zinc Co. is developing a new mine on the Birkbeck lease. A 400-ton mill and power plant is being constructed.

At Millbrig a new zinc mine is being developed on the Graham land for the Vinegar Hill Co. New 300-ton equipment is under construction, the plant to be ready by April 1.

At Galena the Great Western Mining Co. is operating with an independent zinc ore refinery. The Galena Refining Co. has a new zinc plant ready to go into commission. Seven acres of land has been purchased for a more elaborate establishment, should new processes now being tried prove successful.

Galena, January 20.

MICHIGAN

Houghton County (The Copper Country)

(Special Correspondence.)—For 17 days steadily the district has been fighting one of the old time Lake Superior blizzards, with a continuous wind of hurricane force, a steady fall of snow and the thermometer below zero. With railways it is quite impossible to maintain steady service. Snow-piles 25 and 40 ft. high on either side of the deep cuts are common. The railway men who know how to fight these storms, from experience, say that this has been the worst in 20 years. Keeping the main lines open is not such a difficult task, but getting into the sidings that run cars under the shaft-houses causes great difficulties. The storm is preventing the shipment of ore to the mills. Ordinarily it would necessitate shutting down stamp-mills, and a storm of a few days can be cleared up in a day, but this continuous cold, with snow and wind has caused a great deal of trouble. On January 22 there was sign of abatement, but some mills will have to shut down entirely if it keeps up a few days longer. Hence the copper output in January will be fully 2,000,000 lb. short.

There is every reason to believe that the Onondaga has entered the Nonesuch formation—or the White Pine as it now generally is called—the result of the seventh diamond-drill hole indicates the 'swing' of the lode, and this verifies the geological theory on which the president of the Onondaga, R. C. Pryor, presumed when he commenced the work.

South of the Quincy No. 7 shaft, operated jointly with the Hancock, the latter has opened its best ground on No. 68, 69, and 70 levels. Over 300 men are employed at the mine, producing 400 tons daily.

On No. 32 level of the Franklin the shoot of rich ore is 700 ft. long. This lode has been opened at a lower level also.

It is rumored that the Ojibway and Oneco mines are to be re-opened; but nothing definite has been announced.

Houghton, January 22.

It is said that the Calumet & Hecla will probably commence issuing quarterly reports, similar to the great porphyry companies; also an estimate of production for each month.

At the present rate of production the Wolverine is estimated to have 20 years' life.

In 1915 the Mohawk yielded 15,800,000 lb. an increase of 4,700,000 lb. Profits were $1,000,000 more than in 1914, equal to $14 per share, against $4.31.

Owing to a fire in some old workings at combination shaft No. 5 and 6 of the Calumet & Hecla, a U. S. Bureau of Mines rescue-car is at Calumet giving aid. The fire is not considered dangerous.

The New Arcadian company is to sell some if its land to the New Baltic company for $40,000 cash and 14,000 shares in the latter.

On February 1 most of the iron-mining companies in this State will raise wages 10%. This will also be effective in Minnesota. A total of over 30,000 men will benefit.

MISSOURI

Jasper County

The 'Mining Edition' of the *Joplin Globe* for January 16 covers 70 pages, including statistics, progress, and photographs of the zinc-lead region. The output of zinc concentrates in 18 years totals 4,858,023 tons, worth $194,635,410, and 675,828 tons lead valued at $37,025,768.

There was not much change in ore prices during the week ended January 15. The output was 4576 tons blende, 187 tons calamine, and 778 tons lead, averaging $93, $73, and $72 per ton respectively. The total value was $498,619.

Hand-jigging operations on some land near Spring City has been stopped by an order of the Court, until arrangements are made to prevent the sludge flowing on to land of agricultural value.

To drain its land the Missouri Lead & Zinc Co. may install a modern pumping plant costing $8000 or $10,000 at its new Paxton shaft at Joplin. A Diesel engine would be part of the equipment.

MONTANA

Park County

The tungsten claims of N. E. Franklin, H. Schultzel, and F. R. Baldwin at Jardine are to be developed.

Silverbow County

While copper remains at 29c. per pound or over, about 20,000 men employed by the Butte companies will receive $4.25 per day, an advance of 25c. The new rise was effective on January 15. The pay-rolls are now at the rate of $2,100,000 per month.

The Anaconda company has purchased the Butte-Alex Scott mine for $750,000. The present output is 180 tons of ore daily.

It is likely that the Tuolumne will be closed, as the present daily output of 125 tons of 2.5% ore is not profitable. Absorption by the Anaconda or North Butte is possible.

NEVADA

Esmeralda County

Recent development in the Jumbo Extension has given great satisfaction. The Velvet shaft is down 900 ft. New ground is yielding most of the ore. Raise 555-A is producing $60 to $180 ore. Within 180 ft. of the Merger boundary drifts are opening rich ore between 900 and 975 ft. The new vein, opened by a cross-cut from old workings on No. 3 level, assays $63 per ton.

East and west cross-cuts are still being driven from the bottom of the winze from the 500-ft. level in the Sandstorm-Kendall. Fifty tons of $22 to $30 ore every other day is the Atlanta's output, mostly from 1580 ft. depth. Water has interrupted work in the winze below 1750 ft., where good ore is showing. Development at the Kewanas is reported to be satisfactory.

Humboldt County

The late development in the Colligan workings on the Weaver No. 2 of the Rochester Mines Co. is considered by the management one of the most important since the beginning of Rochester. The vein now discloses 4 ft. of $70 ore. It proves the extension of the west vein of the Crown Point No. 1 more than 600 ft. to the south, or an entire distance of 1400 ft. through which this vein has been opened along a strike in Rochester Mines ground. A new vein has been cut in the raise from the Friedman adit of the company, which is now showing 5 ft. of $25 ore. It was found 100 ft. above the adit. Its extent is not known because the raise is still in ore.

Shipments are to be started from the Sheepherder's Dream mine at Willard, under lease to L. J. Kaiser.

From April 1 to December 31, 1915, the Rochester Mines Co.'s mill treated 23,090 tons of ore averaging $14.75 per ton. Bullion recovered was 3131 oz. gold, and 545,959 oz. silver, worth $332,818. Out of the 203 days' work there were interruptions on 72 days.

LINCOLN COUNTY

During 1915 the Pioche district shipped 92,000 tons of gold, silver, lead, copper, and zinc ores to Utah smelters, a record. The Prince Consolidated produced most of this, followed by the Amalgamated Pioche, and Bristol. Freight to Utah is $1.75 per ton. The current year will show a considerable increase.

On January 20 the new mill of the Yuba Leasing & Development Co. at Pioche was destroyed by fire. The loss is $40,000. Arson is suspected as the cause. The plant will probably be rebuilt, according to the president, A. C. Smith. Two men were recently killed in the mine.

Regular shipments of 50 to 60% lead and 20 to 25-oz. silver ore continue to be sent from the Groom mines, in the southwest of this county, to Utah smelters. Teams haul the ore to the Las Vegas & Tonopah line, 57 miles.

NYE COUNTY

Six companies and lessees at Tonopah last week produced 8520 tons of ore worth $178,620. The Extension and West End shipped 83,835 and 52,196 oz. bullion respectively. In the former great importance is attached to the winze being sunk from 1350 to 1540 ft. It is 19 ft. wide and 10 to 12 ft. across the vein. It is intended to make this a three-compartment winze for deeper work.

Some December returns were as follows:

Belmont, 12,706 tons averaging $12.15 per ton, with $80,135 profit; Jim Butler, profit of $22,006 from 3981 tons; and Tonopah Mining, 12,225 tons averaging $12.45, with $56,025 profit. The last named treated ore worth $492,637 in its last quarter, of which $201,048 was net. Other income was $123,210. On January 21, $150,000 was distributed.

WHITE PINE COUNTY

According to G. L. Sheldon in the *White Pine News* of Ely, tungsten was discovered in this county 17 years ago by Charles Gaby. This was on ground of the present United States Tungsten Co., in the Snake range, 12 miles south of Osceola. Developments now consist of a 1700-ft. adit, obtaining a vertical depth of 700 ft. on one vein. An upper adit has opened a 400-ft. continnous shoot. The formation is granite, and the ore mostly hübnerite. A mill is in operation. Six years ago G. G. Sims found hübnerite 40 miles north of Osceola. An extensive deposit has been traced. A mill is working. A 20-ton plant is crnshing scheelite on another property, 8 miles west of Garrison, Utah, over the line in Nevada. Scheelite has been recently found in other districts, probably the best near Mt. Washington, at an elevation of 9500 ft. The veins are small, but high grade.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—The Royal John Mining Co., which has taken over the old Grand Central zinc and lead property, 28 miles east of Santa Rita in the Black range, is now employing 100 men. Work at present consists in developing the orebodies, re-modeling the old mill, (the jigs being replaced by concentrating tables) and constructing a ten-mile road from the mine to the Mimbres Hot Springs road. This company has just blown-in a smelter at Pittsburg, Kansas, for the treatment of concentrates from the Royal John mine. George E. Coxe is geologist, and A. O. Ihlseng is metallurgist for the company.

Santa Rita, January 10.

OKLAHOMA

WASHINGTON COUNTY

The Bartlesville Zinc, Lanyon Starr, and National Zinc companies, operating smelters at Bartlesville, and employing 1200 men, increased wages by 25c. per shift on January 17. Wages vary from $2.35 to $4.50 per day. One reason for this raise was to avert any possible strike, as there has been labor trouble at the smelters at Caney, Kansas, a few miles north. These Bartlesville plants were described in the PRESS of July 11 and 25, and August 8, 1914.

SOUTH DAKOTA

LAWRENCE COUNTY

From isolated pockets in the Hidden Fortune ground the Homestake company has nearly extracted another car of wolframite. The B. & M. hoist and other machinery is expected to be ready in April.

TEXAS

ZAPATA COUNTY

(Special Correspondence.)—A new natural gas field is being developed near the Rio Grande, 50 miles from Laredo. The Boredr Gas Co.'s well has a flow of 30,000,000 cu. ft. per day. There are indications of oil. The gas is to he piped to Reiser, 18 miles, then connected with the line that already goes to Laredo.

A large gas-well was recently brought-in near Corpus Christi by the Guffey Petroleum Co. Gas was struck at 2700 ft., and the pressure is tremendous. The well is 'wild' at present.

The gas fields of north and central Texas were recently investigated by G. C. Matson and E. W. Shaw of the Federal government. They reported that the Petrolia field is 40% exhausted. The Lone Star Gas Co. supplies Fort Worth and Dallas from this field.

Other gas areas are being explored.

Austin, January 10.

UTAH

JUAB COUNTY

The heaviest fall of snow ever recorded is reported from the Tintic district during the first three weeks of January, and it is with difficulty that the railroads are operated.

As long as lead is 4.5c. per lb. and silver 56c. per oz. or over, the Chief Consolidated will pay its 300 men an increase of 25c. per day.

Continued interest is taken in the important shoot of copper at 1000 ft. in the Iron Blossom.

The Utah Minerals Concentrating Co. at Tintic is in the market for tungsten ores. At the plant of the Utah Ore Sampling Co. at Murray the former will pay $22 per ton for 2%, $39 for 3%, $85 for 4%, and $108 for 5% ore.

SALT LAKE COUNTY

The Utah Copper and other companies at Bingham have advanced wages from 15 to 25c. per day, the former effective on January 1 and the latter on February 1, to remain in effect as long as copper is 20c. or over a pound. The principal companies affected by the increase in wages are the Utah Copper, the United States, Utah Consolidated, Utah-Apex, Utah Metals, Bingham Mines, and Ohio Copper.

According to the manager of the Cedar-Talisman Consolidated Mines Co., S. S. Pond, a great deal of 11% zinc ore has been developed, apart from the richer ore. An electrolytic plant of 10-ton capacity, costing $10,000, is proposed for experiments. Sales of zinc and lead ores in 1915 realized $9326. Operations left a loss of $2468. Cash amounts to $1877.

Lessees at the Michigan-Utah at Alta last year mined 4036 tons of dry ore averaging $9.83 per ton, a large decrease compared with 1914.

Summit County

When lead is 5.5c. per lb. and silver 55c. per oz. or over, the Daly Judge, Daly West, Ontario, and Silver King Consolidated, companies at Park City will increase wages 25c. per day. When lead recedes to 5c., and silver rises to 70c. or over, the increased wages will continue in force. When prices of both metals are less than these, wages will revert to the old scale. The Silver King Coalition is expected to offer the same rates. In the Park City district at present miners and 'muckers' are paid $3; machine-men, $3.25; shaft-men, $4; car-men, $3; motor men $2.25; mill men, $3, and hoisting engineers $4 per shift.

Schools and Societies

The University of California has issued its Register for 1914-'15 with announcements for 1915-'16. It covers 936 pages in the various divisions, wherein are given the faculty, courses, colleges, names of students, etc. The second half-year in the academic colleges commenced on January 3. The publication was prepared by the U. of C. press at Berkeley.

The Southern California section of the A. I. M. E. meets at Los Angeles on February 1. The feature of the evening will be the reading of a group of valuable papers on 'Petroleum, its Geology and Technology.' The contributors will be Ralph Arnold, William F. Staunton, Robert B. Moran, and W. R. Hamilton. A full attendance is urged.

The Colorado School of Mines at Golden announces that as its first prospectors' course early in 1915 was so successful, an enlarged course will be held from January 31 to March 4, 1916. Instruction is to include 50 hours in prospecting geology, 30 in chemistry, 5 in metallurgy, 5 in placer mining, 10 in lode mining, 10 in mining claim law, and mine-rescue and first-aid work. The full course costs only $2.

Thirty-three mining men, with experience varying from 1 to 25 years, have enrolled in the 19th annual three months' short session of the College of Mines, University of Washington, Seattle. At the annual smoker tendered the short session miners by the student branch of the A. M. I. E., R. H. Stretch of the Alaska Bureau, Seattle Chamber of Commerce, gave an address on 'The Mineral Belts of Alaska.'

The Colorado School of Mines at Golden is starting to do a good deal of work on flotation, based on the laboratory machines, up to installations that will handle from five to eight tons per day investigation work. The board of trustees has just established a new department, that of research and testing, and all such matters will hereafter be referred to that department and publications made from time to time.

The Mexican Massacre

The following resolution was passed at the meeting of the board of directors of the A. I. M. E. on January 21:

Resolved, That this Board has learned with indignation and sorrow of the unprovoked and brutal murder of 18 American citizens on January 10 in the State of Chihuahua, Mexico, and laments especially the death of C. R. Watson, C. A. Pringle, H. C. Hase, and W. J. Wallace, who were members of the Institute. As these men and their companions were engaged in the lawful prosecution of their work, we trust that nothing will be allowed to prevent or delay appropriate action by our Government concerning the outrage by which they lost their lives.

Resolved, That the sincere sympathy of this Board and of all members of the Institute is extended to the families and friends of C. R. Watson, C. A. Pringle, H. C. Hase, and W. J. Wallace. And be it further

Resolved, That a copy of this resolution be sent to the Secretary of State of the United States, be published in the Institute's Bulletin, in the press, and be sent to the families of the deceased members.

PERSONAL

C. W. Morse is at El Paso.

William Braden is on his way to Chile.

Frank H. Probert was at Oatman this week.

J. H. Tyrrell is leaving Toronto shortly to go to England.

George B. Church has returned from Alaska to New York.

L. F. S. Holland is examining mines at Patagonia, Arizona.

Sherwood Aldridge of New York is at the St. Francis hotel.

Edgar Rickard is due to arrive at New York today on the *Rotterdam*.

G. G. S. Lindsey is expected shortly at Toronto on his return from China.

H. Y. Walker, manager of the Tacoma smelter, was in San Francisco this week.

Wilbur H. Grant has returned from examining a molybdenum property at Shultz, Arizona.

John W. Finch is in New York; he is planning to take a voyage for his health in the Orient.

Robson T. White, manager for the Caucasus Copper Co., has arrived in New York from Batoum.

Ben B. Thayer and L. D. Ricketts expect to sail from New York to Valparaiso, Chile, in a few days.

William Hagel succeeds A. D. Foote as manager of the Tightner Mines Co. of Sierra county, California.

K. Shigeno left Yokohama on January 8 to come to this country to investigate the conditions of the copper market.

Charles W. Morse has been promoted to concentration engineer, a newly created position at the Washoe plant of the Anaconda company.

W. G. Miller and T. W. Gibson of the Ontario Nickel Commission are in Cuba. G. T. Holloway, chairman of the Commission, has returned to London.

M. P. Braffet, member of the executive committee of the American Mining Congress, has been elected president of the Salt Lake Stock and Mining Exchange.

E. L. S. Wrampelmeier, formerly superintendent of the Erie mine at Gaston, Nevada county, California, has taken an office in the First National Bank Bdg., San Francisco.

George S. Rice, chief mining engineer of the U. S. Bureau of Mines, advises that his official headquarters will be at Washington, D. C., after January 15, and not at Pittsburg, Pennsylvania.

T. A. Rickard will deliver a series of lectures on the application of geology to mining at the College of Mining of the University of California, at the following times: 4 p.m. on January 31, February 2 and 4, and 5 p.m. on February 1 and 3.

H. A. J. Wilkens and W. B. Devereux, Jr., have formed a partnership to carry on the general business of consulting mining engineers and mine managers under the name of Wilkens and Devereux, with offices at 120 Broadway, New York. They will be represented by O. F. Westlund at Mexico City and G. S. Duncan in London.

Edward N. Magner, president of the Aurora Mines Co., Nevada, died at Los Angeles, January 1. He was born at Paris, Illinois, June 4, 1858. He went to Leadville, and later to Creede, in the early days of those districts, and was prominent in their early development. Later he operated at Silver City, New Mexico, for 15 years, and from there he went to Salmon City, Idaho, remaining nine years. He was married at Butte, in 1897. His widow survives him.

The Idaho Mining Association met at Boise on January 25. Mining law revision, leasing, and prospecting were discussed.

THE METAL MARKET

METAL PRICES

San Francisco, January 26.

	Cents per pound.
Antimony	44
Electrolytic copper	26
Pig lead	6.35—7.30
Quicksilver (per flask)	$275
Spelter	21
Tin	43
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, January 26.

Antimony: 50% product, per unit	$2
Chrome: 40% and over, f.o.b. cars California, per ton	15—18
Magnesite: crude, per ton, f.o.b.	7.50—10
Magnesite: plastic, no iron and lime, calcined, per ton	50
Magnesite: refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	40—50

Tungsten production will be less on account of the Atolia, California, mill being burned, as noted on the last page of this issue.

New York, January 21.

Antimony: per unit	$2.20
Molybdenite: per lb	1.40

Indian manganese ore, suitable for the production of 80% ferro-manganese, is quoted at 75c. per unit, Baltimore.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 27.—Copper is firm owing to exports: there is a heavy export enquiry for lead; zinc is active and strong.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Jan. 20	56.75	Dec. 15	55.66

The above quotations speak for themselves, a strong and rising market. On January 22 silver worth $370,491 left San Francisco for China. Exports from England during 1915 totaled £3,781,500 to India and £7000 to China, against £5,219,500 and £12,000, respectively, in 1914.

Samuel Montagu & Co.'s 'Annual Bullion Letter' has been issued. We will abstract from it in an early issue.

According to 'The Financial Times,' London, the most striking feature of last year in silver is the fact that for the first time for a long period the normal laws of supply and demand dominated the situation, no forward business preventing speculation.

Tin is quiet at 41.87 cents.

The Wah Chang Mining & Smelting Co. quotes its 'WCC' brand antimony (99.7%) at 43c. spot; February shipment 33c. c.i.f. in bond.

Eastern Metal Market

New York, January 21.

In the past week activity has been monopolized by zinc, for which there has been a good demand for both spot and first quarter deliveries. Prices have advanced day by day. Copper is higher, although the market has been very dull. Re-sale metal has been eliminated from the market and the producers control the situation. For spot copper 25 to 26c. is asked. The market was flooded January 21 with wild reports, some of these to the effect that 30c. had been offered and refused for spot electrolytic. The reports were quickly denied, but there is no question about the market being extremely strong. London is exceptionally strong, despite the plan of the Government to fix the price at a certain figure. Lead has strengthened at London, likewise in the New York market, and while the domestic trade is quiet, some big export orders are understood to be pending. Tin is almost without features of interest in a fairly strong market. Antimony is higher because of the scarcity. Aluminum is unchanged.

The steel mills are wrestling with delivery problems growing out of the pressure of demand and the railroad freight congestion. Three boiler-shops in the State of New York have been compelled to shut-down because they cannot get plates, a product for which the ship-yards have created an enormous demand. Structural material is selling at 2c. and over. Pittsburg, and in view of the further fact that the prices of brick and cement have advanced, building operations are being restricted. Agents for the Allies have placed an order for 30,000 tons of steel-rounds for shells, delivery to be made after the first of July. The price of such rounds ranges from 3 to 4c. per lb. Pig-iron was quiet following the holidays, but is becoming active again. Considering the present rate of steel production there is every prospect of a shortage of ferro-manganese.

ZINC

The dullness referred to last week gave way to an excellent demand, especially for prompt and first quarter deliveries, and quotations have moved steadily upward. Prompt is quoted today at about 18.75c., New York, and 18.50c., St. Louis. An influence which led to the greater activity was the freight congestion in New England, which caused the New York, New Haven and Hartford railroad to declare an embargo on all save perishable freight. Connecting railroads did the same, with the result that shipments from the West were seriously interfered with. Some mills were in such distress that they had considerable quantities shipped to them by express. This week following the good demand for spot and first quarter, there developed a lively market for second-quarter deliveries, and sales were made at 15.50 to 15.75c., St. Louis. February is quoted at about 19.37½c., New York, and March at about 17.75c. But little of the buying is attributed to the galvanizing interests. Exports from January 1 to 20 total 3262 tons.

Sheet-zinc, car-load lots, is quoted at 23c. f.o.b., mill, 8% off for cash.

COPPER

The producers of copper have a firm hold on the situation, and while business is quiet quotations are stronger at higher levels than prevailed a week ago. Spot electrolytic is held at 25 to 26c., 30 days, delivered, and Lake is quoted at the same range but is entirely nominal. There is little or no re-sale metal offered, either Lake or electrolytic. The situation at London is strong, but peculiar, as the electrolytic quotation January 20 reached £117, despite the announcement that Great Britain had fixed £100 as the maximum price for refined copper. Since the announcement appeared there have been three advances in electrolytic. Information as to what the British government is doing is meagre. The quiet that now prevails in the domestic market is no cause for surprise in view of the vast quantities which were taken by consumers up to the end of December, and well into January. Meanwhile the producers are in a most comfortable position, and can afford to maintain prices and await the development of further requirements. An interesting announcement is that the Department of Commerce will discontinue, at the end of the present month, its weekly announcements as to the exports and imports of copper. It is explained that business is now more settled, and that the reports are not as useful or important as they were. Stocks of refined copper in Great Britain and France continue to decline. Their total on January 15 was 11,681 tons, against 12,341 tons at the end of December. Exports up to January 20 totaled 14,230 tons. Exports in 1915, as compiled by C. Mayer secretary of the New York Metal Exchange, totaled 270,704 tons, against 360,229 tons in 1914, 382,940 tons in 1913, 327,965 tons in 1912, and 336,801 tons in 1911. Mr. Mayer apportions the exports in 1915 and 1914 as follows, in tons of 2240 lb.:

	1915.	1914.
United Kingdom	79,585	87,556
France	98,200	66,326
Germany	.....	88,452
Holland	1,678	58,940
Belgium	.....	2,876
Austria	.....	13,809
Italy	44,705	26,068
Denmark	2,426	3,950
Norway and Sweden	19,958	8,649
Russia	20,456	425
China and Japan	119	1,910
Sundries	3,577	1,268
Total	270,704	360,229

LEAD

A week ago the market was weak because of the announcement that Great Britain would undertake the regulation of both buying and selling lead in England. The tone of the market became weak, but prices did not suffer much. Since then London has gathered strength, the quotation for spot on December 20 being £31 15s., and the better tone has been reflected here. The principal interest adhered to 5.90c., New York, until January 21, then advanced its quotation to 6.10c., an advance of $4 per ton. St. Louis stood January 20 at 5.82½c., but in the week has been as low as 5.70c. The domestic demand has been quiet, but there are continued reports of large export inquiries. If business has resulted from these it has gone to the few larger producers. Exports from January 1 to 20 totaled 3355 tons.

TIN

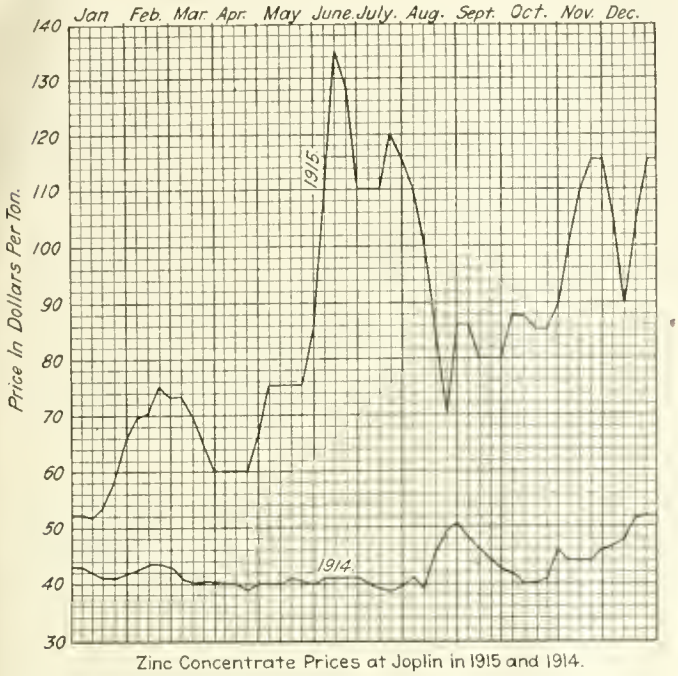
The trouble with delayed cables from London lasted until the end of last week and demoralized business at New York. This week messages have come through more promptly, and on one or two days a good business has been done. The cable delays are attributed to the severity of the censor which created a congestion. Spot-tin was quoted yesterday at 41.50c. The arrivals this month total 3100 tons, and there is 6000 tons afloat, so there would appear to be no reason for consumers to worry over the sufficiency of the supply.

ANTIMONY

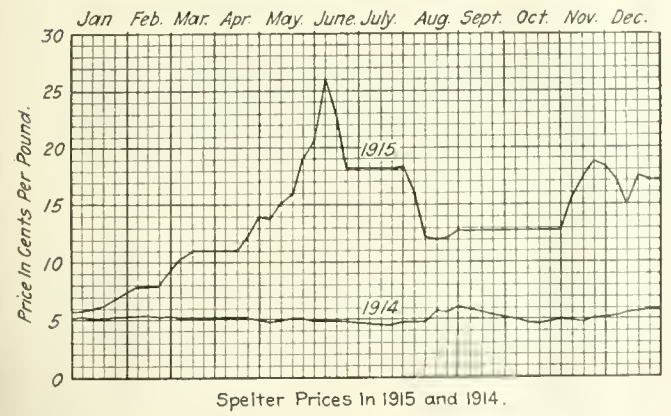
The market is without feature except for the continued scarcity of spot metal which has caused quotations to become still stronger. Both American antimony and Chinese and Japanese grades are quoted at 42 to 42.50 cents.

Ore and Spelter Price Comparison

The accompanying chart, from the *Joplin Globe*, shows the prices for zinc concentrate (60% metal), and zinc in the Missouri-Kansas-Oklahoma region during the past two years. The generally close agreement in market movements is easily



Zinc Concentrate Prices at Joplin in 1915 and 1914.



Spelter Prices In 1915 and 1914.

observed, although at two periods the two commodities did not move together as much as ore producers would have liked. The average for concentrate in 1915 was $77.84 per ton, and spelter 14.16c. per pound.

Antimony in 1915

Antimony prices in 1915 were probably the highest known since the metal became a regular article of commerce. The high prices led to the largest production the United States has made, and probably the same statement is true for the world's production. According to preliminary figures collected for the U. S. Geological Survey by Frank L. Hess, the production of antimony ores in the United States is estimated to have been about 5000 tons containing 2000 tons of antimony, valued at about $325,000. The largest previous domestic production was in 1892, when 150 tons of metal was produced in San Francisco from Nevada ores, and 380 tons of ore containing 55% of antimony was exported. Practically all operations of the past year were new, most were small, and they were widely scattered so that it is difficult to obtain close figures immediately after the close of the year.

Antimony, which in July 1914 had been down to a monthly average price of 7.11c. for Cookson's, and from 5.44 upwards for other brands, rose gradually though unsteadily, to the end of 1915 when Chinese, Japanese, and American antimony were quoted at about 40c. a pound. Quotations for Cookson's antimony ceased in May, 1915, some time after an embargo had been declared against the shipment of antimony metal or ores from the British possessions, and 50c. a pound is said to have been paid for it about June 1, when Chinese was selling for about 35c. or less. In the fall, American antimony appeared on the market for the first time in many years. At first it sold slightly below Chinese and Japanese, but was soon quoted at the same price. Miners and smelters, apparently thinking that the high prices would be temporary, did not begin production as quickly as they otherwise might have done, but before the close of the year properties in Alaska, California, Idaho, Nevada, Oregon, Utah, and Washington were producing. Prices for ores ranged from $1 to $2.10 per unit of antimony. At first, only ores carrying 50% or more antimony were in demand, but before the close of the year 20% ores were being shipped from Nevada.

From Alaska, according to data collected by Alfred H. Brooks, about 685 tons of stibnite ore carrying 58% metal was produced in the Fairbanks district from properties on Eva, Vault, Treasure, and Chatham creeks. It is reported that 132 tons was shipped from Nome, but it seems probable that more was mined.

The largest production was made from deposits near Wild Rose springs, on the north-west slope of Telescope peak in the Panamint range, California. These deposits have been known for many years, but have been too far from railroads for profitable exploitation until the past year when prices were high and a branch railroad was built to Trona on Borax lake, within about 25 miles of them. The deposits contained considerable antimony ocher as well as stibnite, and were mined by the Merchants Finance Co. (Western Metals Co.) The same company operated deposits 30 miles north-east of Mojave, which are 10 miles from the S. P. R. R. at Neuralia, in Kern county. Other deposits were mined in California at many points in Kern county, in the eastern end of San Benito county, and on Moore's Flat near Grass Valley. In Nevada considerable quantities were mined at many points mostly in the north-west quarter of the State with Lovelock as a centre, but ranging from Pass canyon in the Pine Forest range southward to the vicinity of Tonopah and eastward to Joy.

Oregon, Washington and Idaho produced small quantities of ore, and in Arkansas a company was organized to work old properties west of Gilham.

The Chapman Smelting Co. of San Francisco which had been idle for a number of years again started the smelting of antimony ores. The company mined ore at Bernice, 60 miles east of Fallon, Nevada, and brought ores from other points in the Western States, Alaska, and British Columbia.

The Merchants Finance Co. built an antimony smelter at Industrial Harbor, Los Angeles. Besides operating California mines the company operated mines in Nevada and brought ores from the Western States, Alaska, and foreign countries.

The Antimony Smelting & Refining Co. of Seattle started a plant at Van Asselt the last of the year and made oxide, but metal is to be smelted also.

The International Smelting Co. bought ores to be smelted at its South Chicago plant. The Great Western Smelting & Refining Co., of Chicago, and the Pennsylvania Smelting Co. of Pittsburg, have also smelted some ores. The Magnolia Metals Co. found so much difficulty in obtaining needed supplies of antimony at a reasonable price that it bought and mined ores in Nevada, smelting them at Brooklyn.

Harshaw, Fuller & Goodwin Co., of Cleveland were in the market for pure ores from which to make antimony salts,

heretofore made from Chinese crude antimony. [Notes on antimony production in China will appear soon in the Press. Editor.]

The tendency has been for some companies to go to an expense for mine development, machinery, and mills, not wholly warranted by the circumstances. The present high prices are necessarily temporary. The Chinese deposits are extensive, and worked by very cheap labor, and other deposits are being developed in other parts of the world, and as soon as the War is over, and possibly before, prices will probably drop to a level with or close to those of 1914.

Tungsten in 1915

The production of tungsten ores in the United States during 1915 broke the record, and was apparently equivalent to about 2165 short tons of concentrates, carrying 60% of tungsten trioxide (WO_3), and was valued at more than $2,000,000. These figures are based on preliminary returns to the U. S. Geological Survey. The largest previous output of tungsten ore was in 1910, when 1821 tons was produced.

Conditions and prices in the tungsten market were unsettled and somewhat anomalous. Although the price in the latter part of 1914 was $9 or more a unit, 60% ore was sold in the early part of 1915 as low as $5.80 a unit, so that tungsten mining did not start very briskly. Early in the summer, however, floods of orders for munitions of war caused a great demand for high-speed steels, to be used in cutting shells, rifle-barrels, etc.; an embargo was declared by the British government on the export of tungsten ores from any part of the British possessions, and there was soon a country-wide scramble for tungsten ores. Probably no one foresaw the height to which the price of tungsten would rise, and some operators contracted for ores at prices which in ordinary years would be high, but which were soon exceeded by several hundred per cent. Tungsten metal was also contracted for at prices much below those afterward reached. In the fall the prices of tungsten reached unheard-of heights; $48 per unit was paid for numerous lots, $50 for some, and even higher prices were reported. The prices moved upward so rapidly and unexpectedly that strenuous tungsten prospecting did not follow at once, but early in the fall a large number of men were in the field looking for deposits.

The mining activities are described by Frank L. Hess in some detail. The output of the Boulder (Colorado) field was for various reasons not increased as had been hoped. Many properties had been worked by leasing, so that there was no development of orebodies, for the ore had been removed as fast as it was exposed, and it is reported that in the Conger mine, whose shaft was sunk below the 800-ft. level, development was disappointing. Sinking is said to have been continued. The output of the district was estimated by the Boulder County Metal Miners' Association as equivalent to 960 tons of 60% concentrate.

In the Atolia (California) field there were great developments. The Atolia Mining Co. is reported to have employed more than 300 men, and many men worked the desert sands in the vicinity for float scheelite. P. J. Osdick discovered rich ore east of the Atolia Mining Co.'s property and made large profits. On and near the Baltic claim a number of men worked the gravel of a shallow gulch for scheelite and the sands on the Sunshine and other claims are also reported to have been worked at a profit. Several gold mines also produced scheelite. The Consolidated Gold Mines, in Randsburg, had found water at a depth of about 500 ft., and this has been piped to the Atolia company's mill, about five miles distant. Formerly water was hauled on the railroad for a distance of about 50 miles. The company is reported to have erected a new mill to treat its tailing.

Several discoveries of tungsten ores were reported from Gilpin county, Colorado, but the most extensive discoveries, as indicated by the number of outcrops, were made in White Pine county, Nevada. Veins of scheelite were found at several places between the Minerva district, 30 miles south of Osceola, and Cherry creek, 50 miles north of the settlement. Some of the veins were formerly prospected for precious metals, but the scheelite was not recognized. The hübnerite mine and mill 12 miles south of Osceola were actively operated toward the close of the season; the mill at Camp Bonita, on the east side of the Snake range, was operated part of the year, and mills were erected or started by the St. Anthony Mines Co. at Toy (Browns), Humboldt county, by A. R. Shepard and associates in the Reagan district, and by the Doyle Mining Co. in Sacramento Pass, White Pine county. Some hübnerite was dry washed from desert sands at Round Mountain and Spanish Springs, Nevada.

The dumps of gold mines at White Oaks, New Mexico, were worked over for hübnerite and yielded a considerable quantity of concentrates, and at Tip Top, Arizona, a mill was under construction to work the tailing and dumps of the old Tip Top silver mine for the wolframite they contained.

Mills were erected by the Primos Chemical Co. at Dragoon and by the National Tungsten Co. at Arivaca, Arizona, for treating the tungsten ores, and tungsten was produced at these places and at Camp Wood, Yucca, Oracle, and other points.

At Lead, South Dakota, the Homestake gold mine produced wolframite from the claims west of the great open-cut, and the Wasp No. 2 mine, two miles south, produced a considerable quantity of ore. It has erected a concentration plant. Only a little ore was produced in the southern Black Hills.

Small quantities of tungsten were produced in Idaho and at Silverton, Colorado, and a few hundred pounds was saved from the old concentrates of the gold placers at Nome, Alaska.

The wolframite deposits on Tungsten peak, near Cathedral peak, 45 miles northwest of Oroville, Washington, became the property of the Tungsten Mines Co., and the new owners produced some ferro-tungsten in an electric furnace at Tacoma.

The price of tungsten as metal or ferro-tungsten rose from $1 a pound in January to $8 in December. In the same period tungsten steels increased in price from 60 or 75c. to $3 a pound.

(Special Correspondence.)—The new mill and equipment of the Atolia Mining Co., which was only recently completed, was partly destroyed by fire today. The plant was the only one for producing tungsten concentrate on the Pacific Coast. Atkins, Kroll & Co. of San Francisco were its managers, with Charles Taylor as superintendent. The mill began operating at full capacity of 100 tons per day about January 1, and had not stopped since then. The disaster means about 40 days' shut-down, which will affect 400 employees and every resident of Atolia, nearly 600 people. The cause is said to have been back-firing in the gasoline engine in the hoisting room, where the flames spread by contact with distillate leakage to the whole structure. There was $56,000 insurance, and the loss is said to be $40,000.

Atolia, California, January 24.

Manganese production of the United States in 1915 was nearly 6000 tons, compared with 2635 tons in 1914. Prices rose from $12 to $22.50 per ton for 50% ore. It is not likely that domestic deposits will make more important contributions to the supply. Imports from India were one-twelfth normal; from Russia, negligible; and from Brazil, over twice the average for the three preceding years.

Carnotite ores produced in Colorado last year contained 23.4 tons uranium oxide and 6 grams radium, and 635 tons of vanadium, against 87.2, 22.3, and 435 tons, respectively, in 1914.

EDITORIAL

T. A. RICKARD, Editor

A RECOVERY of 95.77% zinc is claimed for the Butte & Superior concentrating mill in December last. This is much the highest extraction recorded at this flotation plant. At the Braden, in Chile, the copper recovery even now is only 77%.

ANACONDA is synonymous with progressive metallurgy and the courage to scrap plant when necessary. We take pleasure in publishing the first of a series of articles on the Washoe reduction works by our friend, Professor L. S. Austin, now resident at Salt Lake City.

YUKON yield of gold in 1915 is estimated at $4,750,000. The most notable event was the working of claim No. 21 on Eldorado by one of the Yukon Gold Company's dredges. As this ground was virgin, the clean-up is reported to have amounted to $500,000 in gold.

DISPATCHES from New York state that the financial groups have notified the administration at Washington that they "positively decline to finance the Carranza government in Mexico." This is important, if true, and will embarrass the Administration in its effort to strengthen the *de facto* government of Mexico.

VALUATION of mines is a subject that must be discussed periodically. The mathematical basis of it may not always seem vital to work in the field, but any line of reasoning on such matters should be checked occasionally by the logic of mathematics. We take pleasure in publishing a careful article by Mr. F. Sommer Schmidt on this subject.

SUNDRY people have awakened recently to find themselves rich. Among them are the operators of quicksilver mines. Thus the New Idria company which in 1911, 1912, and 1913 earned from $50,000 to $65,000 per annum, ran behind $45,000 in 1914, when quicksilver was $48 per flask, made $100,000 in 1915 when the price averaged $85.80, and will make nearly a million dollars in 1916 with the metal ranging from $130 to $300 per flask.

GOLD was produced in the Transvaal in the year 1915 to the amount of 9,093,671 ounces, worth £38,620,461 or $187,946,473. This compares with 8,394,322 ounces in 1914, and 8,798,335 ounces in 1913. The record output was made in 1912, when it was 9,113,476 ounces. The dividends for 1915 amount to £7,617,561, which is £455,875 less than the total in 1914, but this decrease is largely due to the large bonuses distributed in the latter year by the Robinson and Ferreira companies, as against one bonus by the Meyer & Charlton last year.

WE note that the Mining and Metallurgical Society has awarded its annual gold medal to Mr. James F. Kemp, Professor of Geology in Columbia University. The medal will have appreciated much in value thereby. As our readers are aware, Professor Kemp has had to take a rest for several months in consequence of the effects of overwork. We hope that he may convalesce rapidly and soon resume duties of great usefulness. He is the kind of man to be missed.

OATMAN has been cheered by the discovery of another important orebody on the 400-ft. level of the Big Jim mine. This apparently is one of a series of bonanza ore-shoots along the main fracture of the district, now exposed in the United Eastern, Tom Reed, Big Jim, and Black Eagle properties, a distance on the strike of two miles. The Big Jim, we hear, is under thoroughly competent management and will be developed systematically and intelligently.

TEXAS covers an area of one-eleventh of the United States, omitting Alaska and the islands, yet Texas is big enough to contain the whole of Germany and England. The foreign trade of Germany in an average year, such as 1913, was 14% larger than that of the United States, and that of the United Kingdom was 59% larger. In short, the United States "has been living commercially as well as politically largely within itself." The development of a continent has taxed its energies and created a domestic commerce that, until recently, has eclipsed its foreign trade.

IT may not be known generally to the mining public that all the publications of the U. S. Geological Survey, including professional papers, bulletins, and water-supply papers, are available for distribution at the local office of the Survey, at 303-305 Custom House building, San Francisco. Moreover, the complete library of all the publications issued by the Survey from its foundation is on file and is available for reference. A full set of the separate pamphlets on the commercial minerals of the entire country is issued annually, and copies of these may be obtained gratis. In connection with such subjects a complete bibliography is available for con-

sultation. All the maps of the entire United States, geographic and topographic, covering every State in the Union and the district of Alaska, can be seen at the same office. Besides this vast amount of inanimate matter, the visitor will also be privileged to meet Mr. Charles G. Yale, statistician in charge.

KINDNESS has its reward, as wrong has its Nemesis. We have heard more than one story of escape from death in Mexico by reason of a grateful remembrance on the part of an executioner. The latest is that of an American who, with seven others, was lined up against a wall ready to go the long journey on the volley from a firing squad of bandits. Suddenly one of the latter points at our friend and calls out: "Don't kill that man; he is a good man: I worked for him as a foreman in a mine, and he treated me well!" The captain of the firing squad commands him to step forward from the edge of the grave and he is released.

WITH its fatal facility for faking information, the local press has published a cock and bull story alleging that ammunition is being manufactured at the Butters laboratory. This is only excused by the fact that Mr. Charles Butters is making aluminum dust, by use of the method described in our issue of January 22, this product being employed by him as a precipitant for gold and silver in cyanide solutions. It happens that aluminum dust is now being combined—in Europe—with ammonium nitrate to form the new and powerful explosive ammonal, as explained in our issue of January 8. Agents for the Russian government, being wide awake, read our paper and learned that Mr. Butters was making aluminum dust; whereupon they bought 10 tons of that substance for shipment to Russia, in order to make ammonal. These are the facts. If the *Morning Scream* and the *Evening Howl* read the MINING AND SCIENTIFIC PRESS they would be better informed on technical matters in their home territory.

CYANIDE consumption in the United States at the present time amounts to about 2200 tons, of which Nevada alone requires 1600 tons. The price is 16 cents per pound for 100% KCN at New York. Thus the War has caused a rise of about 2 cents per pound. The retail price in San Francisco is 30 to 32 cents. Last year the consumption was a little larger than it is now. The whole supply comes through the Roessler & Hasslacher Chemical Company of New York, to whom, we are informed, the mine operators have the most kindly feeling, because that firm did not take advantage of them in the times of stress created by the War. A large tonnage of cyanide is reported as having been interned in Holland, when on its way from Germany to New York. As most of our readers are aware, the cyanide requirements of the mines under the British flag are being met by the Cassel Cyanide Company, of Glasgow, with whom the British government made an agreement soon after hostilities began, to furnish cyanide at 8½ pence per pound, with an automatic reduction in the price gradually so that at the beginning of 1917 it will be back to the price, 7 pence, prevailing before the War. This arrangement has proved efficacious, the Cassel works having been enlarged in capacity so as to provide the quantity required. Fortunately for the supply of this necessary chemical, the demand from Mexico has been small, otherwise the closure of German sources of supply would have been felt more keenly. On average, a silver ore requires four times the quantity of cyanide consumed in the leaching of a gold ore.

A Professional Matter

Anything that concerns the welfare of the mining profession is our business. This journal endeavors to be a chronicle of professional activities and an exponent of professional ethics. Therefore we publish a copy of the contract made by the American syndicate representing the Minerals Separation company with metallurgists in the employ of its licensees in the use of a patented method of treating ores by flotation. We have no quarrel with the gentlemen of the Minerals Separation company except as to their efforts to stifle information concerning the technique of a branch of metallurgy now of great importance to all those engaged in mining. That policy on their part causes us to be prejudiced against them, but it does not make us unfair to them. With this preamble, we proceed to ask our readers to read the copy of a contract with a metallurgist and then the legal opinion of an accomplished member of the San Francisco bar. When we heard that such contracts were being enforced, we inquired into the terms and inferred that they were invalid, but before coming to a definite conclusion we decided to obtain a trustworthy legal opinion. As will be seen, Mr. C. Irving Wright is of the opinion that the agreement is "without valuable consideration and unconscionable." The reasons are clearly stated: a *quid pro quo* is lacking. The Syndicate does not bind itself to teach the metallurgist anything essential concerning its technical operations, for it will afford him merely "an opportunity of acquiring technical knowledge," and it can keep him "on its staff" for only just so long as it pleases; and in practice, it pleases to keep him for a very short time and to show him very little indeed. The metallurgist likewise is free both to quit this pseudo-instruction whenever he pleases and also to resign his employment with the licensee whenever it suits him. This pretense of giving an insight into the process and of binding the metallurgist not to divulge what he has learned is childish in its unreality, but the seriously objectionable feature of the whole arrangement is the obligation of honor placed upon the metallurgist not to divulge what he has seen or learned while in the laboratory either of the process-company or of its licensee. That obligation is without limit of time and therefore shackles his professional freedom indefinitely. To a careless or dishonorable man, the agreement is a scrap of paper; to an honorable man

—and we are only concerned with such—the signing of this agreement involves loss of freedom in the exercise of his knowledge and skill. He cannot go elsewhere and use what he has learned, he cannot accept a retainer from another client, because he has bound himself not to disclose any improvements even imagined by him or ideas suggesting themselves to him while under employment with the Syndicate or its licensee; he has also obligated himself for the rest of his life not to divulge or communicate any facts concerning the metallurgical operations of the Syndicate. And this professional subserviency is to be the consequence of having been placed temporarily on the staff of the Syndicate "for such a period as it [not he] deems advisable." In short, the metallurgist sells himself for a mess of pottage. Whatever the legal value of the document, and as to that we give the decision of one qualified to pass upon it, we venture to express our opinion on the professional aspect of the matter, namely, that the signing of such an agreement is unprofessional because it cannot be fulfilled without either the loss of professional efficiency or the sacrifice of professional honor.

Getting a Job

In a recent issue of the Colorado School of Mines Magazine the youthful editor writes feelingly on the difficulty of getting 'jobs,' not 'positions,' the latter being regarded as belonging to an order of things beyond the graduate's immediate horizon. According to our Golden contemporary, the chances of employment improved enormously during the second half of 1915, nearly as many engagements resulting in those six months as during the preceding eighteen. The improvement in the technical-labor market is imputed to the demands of the chemical and powder companies, which relieved the congestion due to the closing down of mines in Mexico. At this School of Mines there is a Capability Exchange, where the graduates register their experience, acquirements, and specialties. For each job obtained the recipient pays a fee, which, we presume, pays for the maintenance of the bureau. That is one way—and a good one—of obtaining employment. The subject, however, is a wide one and worthy of attention. Our own experience is that a young man should arrange that when he begins his career he will have a benevolent uncle engaged in the profession for which he has been trained. That is an excellent way of getting first aid in professional preferment. The next best thing to do is to cultivate the acquaintance of kindly elderly gentlemen who may stand *in statu avunculi* and take sufficient interest in the budding engineer to give him employment or speak favorably of him to some friend at the club that has 'invested' in a mine. Another method for throwing bread upon the waters in the hope that it may return buttered after many days is for the young graduate to call upon or otherwise obtain an introduction to the mining engineers sufficiently his seniors to be patrons as regards employment. Most older men will give a few minutes willingly to a youngster who approaches them with proper courtesy; for the senior, unless he be a bear or other brute, will remember his own troubles in the days before his career had gathered momentum. In short, we advise young men to know as many of those engaged in mining as possible. To know men is to be known of them. The knowledge of men is capital no less, if not more, than the knowledge of things. That does not mean making a nuisance of oneself by bothering busy men inopportunely. Not to be known is better than to be remembered unpleasantly. If he be in a mining community, let the youngster call on the senior members of the profession when a reasonable excuse offers. Above all, let him be willing, at any time or place, to prove himself useful. The present writer remembers making a map of a smelter gratuitously for an old and kindly duffer who reported him subsequently as a highly intelligent young man. On another occasion he gave a pretentious expert some data on the local geology without seeming to appreciate the elder's ignorance of essentials. In a third instance he took pains to show a visiting engineer through the mine and was remembered in later years by the offer of a superintendency. Much of the success of life depends upon apparently fortuitous circumstances; to them, plus the readiness to make the most of them, we owe the opening of those doors on which is written on one side PUSH and on the other PULL. In this flux of phenomena called life, as Tyndall phrased it, the chief requisite is to have the qualities best adapted to usefulness at a given time and place. A young man must be ready to tackle anything. He who specifies the few things he cares to do and raises frivolous objections to trying this or that is likely to be sidetracked. The proper way is to state clearly the work in which you have had experience or consider yourself qualified to perform, following that with a cheerful expression of willingness to help in any way. The employer, if sensible, will not put a young man to doing something for which he is unfitted, but will either ascertain his strong points or give him a chance to acquire proficiency. One thing the recently fledged graduate should remember, and that is that his first 'job' is largely a gift, the chance to make himself worth his pay after a while, but not a commercial exchange between labor or brains or both and capital. Apart from purely manual work, in which immature men are not proficient at the outset, the first employment that comes to the graduate represents the offer of a chance to learn; in short, the young man is paid for more than he gives, at first; later he may give more than he is paid; finally he reaches a point where engagements are on a basis of fair exchange. The moral is that if in his third or fourth year he gets too little, he should remember that in his first and second year he was overpaid. After all, to a starter in life the pay is a secondary matter, unless he has untimely burdened himself with the responsibilities of a mate; the main thing is to learn, to amass knowledge, not money; to accumulate experience, not shekels; as against the day when both the knowledge and the experience can be capitalized to

profitable advantage. One word more: a young man casting about for a chance to place his feet on the first rung of the ladder of advancement is likely to meet with discouragement, sometimes in depressing sequence. Such an experience has been shared by most of us. Let him keep a stout heart, for such checks are often blessings in disguise, if he will use them to advantage, as, for example, by utilizing the opportunity to study during periods of non-employment. Even a blunder or a failure at first may prove good discipline as against the time when, as Mr. Woodrow Wilson has phrased it, a man "comes to himself."

Elm Orlu v. Butte and Superior

On another page we give our readers some excerpts from the opinion in this case as handed down by Judge Bourquin on January 22. We would have liked to reproduce the whole of it verbatim, but the exigencies of space did not permit. The case, in its evidence, argument, and decision, affords a timely comment on the anomalies of the extra-lateral idea of mineral ownership implicit in the mining law. The Judge himself had been a hoist-engineer at one time on one of the properties in controversy and he was not without acquaintance with the geologic structure of the mining district in which he lives. During the course of the trial he decided to go underground himself and see the evidence concerning the main points at issue, namely, whether the two veins united or crossed each other. As the preponderance of evidence did not support the idea of union, he finds that they do not unite. He concludes that the circumstances are such that reasonable and learned men may honestly differ in their interpretation of geological phenomena on account of the internal slips in the larger lode and the complexity of the faulting that has confused the rock-structure. With this conclusion most of us will sympathize. We marvel often how the learned gentlemen employed as skilled advocates in these cases can be so positive in regard to the meaning of evidence that may seem to us to be at best inadequate, contradictory, or confusing. We wonder also how half-a-dozen scientific men on one side can differ so radically from an equal number equally scientific on the other side when both have had access to the same facts. Apparently it is not good form on the stand to express the natural hesitation of the scientific observer when called upon to deliver an opinion upon insufficient evidence: that type of philosophic modesty is out of place; instead it is usual to assert conclusions with the confidence of one who was present on the occasion when the Great Architect made the veins or lodes in question. A geologist whose diagnosis left him doubtful as between a crossing and a union of veins would be considered a poor witness; yet we are frank to say that such doubt would obtrude itself into the minds of the majority of intelligent observers detached from litigation. Such observers also would confess that to define the limits of generous mineralization with a view to placing a finger on the boundaries of a lode is a task incapable of scientific treatment, because the limit is drawn on economic rather than scientific lines, that is, it is based on the assay rather than the microscope. The Judge shows respect for the group of clever men engaged as witnesses or 'experts' in this case and gives them credit for a desire to elucidate the truth, but he is fully alive to the warping of scientific vision when subject to the distortion of partisanship. A touch of humor is injected by his remark that both parties seem to have halted development at points apparently vital to the elucidation of the chief problem, "as though fearful of results damaging to their theories." Undoubtedly a theory can be handicapped by a superfluity of facts. Probably the need of further development at specific points was more evident after, than before, the trial. Incidentally, we may remark that among the distinguished experts were one or two geologists prominent in the propaganda for a revision of the mining law, and we do not doubt that this suit will strengthen their belief that the interpretation of the extra-lateral right to complex cases of faulting and vein-crossings is beyond the ability of any judge, or even the most skillful mining geologist. Indeed the little knowledge that the court may have of practical mining and of the elements of geology may easily prove, in the case of a man less sagacious than Judge Bourquin, an obstacle rather than an aid to a correct decision, meaning thereby, one in accord with all the facts if they were known, which, of course, they never are. A recent case at Tonopah, where the judge likewise knew something about mining, afforded a good example of the undesirable introduction of geologic theory on the part of the court itself. In this case a far-fetched interpretation of the evidence on the part of the litigants was supplemented by a quasi-scientific theory contributed by the judge, who, neither by training nor by knowledge, was competent to take part in the scientific discussion, however competent to pass upon the evidence on such a subject when submitted by others. As a matter of fact the effort to arrive at the truth in a case like the one at Butte is a solemn farce, for not sufficient data are available for a clear-cut decision, as is proved by the fact that the labors of a good judge and ten clever geologists terminate in an obvious compromise. We need a revision of the mining law, and we need quite as much a change in the method of eliciting the facts on which a judicial decision can be based. Instead of ten experts, five on a side, it should be possible for the court to select three as his advisers in regard to the geologic factors. Then instead of being skilled advocates the three geologists would become real witnesses—scientific in the true sense. Such a procedure would in course of time lead to the selection of men known to be keen observers, lucid expositors, and unbiased witnesses. Employment for such duties would become highly honorable, and equally useful. Litigation would be abbreviated and rendered less costly. Law-suits would become less haphazard in their results and justice would more nearly prevail, within the limits of human fallibility.

Minerals Separation Contracts and Metallurgists

We give herewith a copy of a contract enforced upon a metallurgist in the employ of a licensee of Minerals Separation, Limited. We follow it with a legal opinion. The matter is discussed on our editorial pages.

THIS AGREEMENT made this — day of ———, A.D. 1915, between MINERALS SEPARATION AMERICAN SYNDICATE (1913) LIMITED, whose registered office is at 62 London Wall, London, E. C., England, hereinafter called the Syndicate, and which expression shall be deemed to include not only the Syndicate, party hereto, its successors and assigns, but also any company or firm which may be affiliated with the Syndicate or which may take over any part of its business, of the one part, and JOHN DOE of ————, of the other part, whereby it is agreed as follows:

The Syndicate shall afford said JOHN DOE an opportunity of acquiring technical knowledge and training relative to the processes and apparatus for the concentration of ores and tailings known to and exploited by the Syndicate by temporarily placing him upon its metallurgical staff for such period as it deems advisable to that end; in consideration whereof the said JOHN DOE agrees to disclose and assign to the Syndicate all inventions, improvements and discoveries made, conceived, developed or completed by him while thus employed relating to the treatment of ores or tailings or to the business of the Syndicate, and that he will from time to time, upon request of the Syndicate, make application through the patent attorneys of the Syndicate for letters patent of the United States and any and all other countries for such inventions, improvements and discoveries, and assign forthwith all such applications and the letters patent theron to the Syndicate or to any such person or persons as it shall designate, and he hereby authorizes the Syndicate to take out foreign patents upon its own application or the application of such person or persons as it shall designate for said inventions, improvements and discoveries, should the Syndicate elect so to do, in any country or countries where such procedure is lawful, all necessary costs and expenses of making such applications and assignments and procuring such letters patent to be borne and paid by the Syndicate; and the said JOHN DOE agrees to give the Syndicate and its attorneys all reasonable assistance in preparing said applications and in drawing the claims thereof, and from time to time, on request, to execute all papers and do all things that may reasonably be required in order to protect the rights of the Syndicate and vest in it or its assigns the inventions, improvements, discoveries, applications and letters patent herein provided and give to the Syndicate the full benefit thereof. And the said JOHN DOE further agrees that he will not at any time, either while upon the metallurgical staff of the Syndicate or thereafter, divulge or communicate to any person or persons, corporation or corporations, other than the directors or the general manager or the chief engineer of the Syndicate or any agent or attorney authorized or appointed by it, any trade or business secrets, operations or processes of the Syndicate, or any of the affairs of the Syndicate or matters relating thereto which have or may come to his knowledge in pursuance of such employment.

Signed, sealed and delivered by the said MINERALS SEPARATION AMERICAN SYNDICATE (1913) LIMITED, and the said JOHN DOE, the day and year first above written.

(Signed) Edward H. Nutter, Chief Engineer,
MINERALS SEPARATION
AMERICAN SYNDICATE (1913) Ltd.
(Signed) JOHN DOE.

The Editor:

Sir—You ask my opinion as to the legal effect and validity of the attached form of agreement imposed by Minerals Separation American Syndicate (1913) Limited upon engineers in the employ of licensees using its patented process.

By the contract the engineer "agrees to disclose and assign to the syndicate all inventions, improvements and discoveries made, conceived, developed, or completed by him while thus employed relating to the treatment of ores or tailings or to the business of the Syndicate," and that "he will not at any time, either while upon the metallurgical staff of the Syndicate or thereafter, divulge or communicate to any person or persons, corporation or corporations, other than the directors or the general manager or the chief engineer of the syndicate or any agent or attorney authorized or appointed by it, any trade or business secrets, operations or processes of the syndicate, or any of the affairs of the Syndicate or matters relating thereto which have or may come to his knowledge in pursuance of such employment."

The consideration for these agreements of the engineer is stated to be the agreement of the Syndicate that it "shall afford said" engineer "an opportunity of acquiring technical knowledge and training relative to the processes and apparatus for the concentration of ores and tailings known to and exploited by the Syndicate by temporarily placing him upon its metallurgical staff for such period as it deems advisable to that end."

It is needless to point out the embarrassment to which an engineer who signs this agreement may, if it be enforceable, be subjected during the future practice of his profession. It would always be open to the Syndicate to contend that any invention relating to the subject matter of the agreement, and brought forward by the engineer in his subsequent career, was in fact made or "con-

served" by him while "on its metallurgical staff." The engineer would, also, always be suspect if he should afterward give advice concerning, or be engaged in, work that could be considered as involving "any trade or business secrets, operations or processes of the Syndicate, or any of the affairs of the Syndicate or matters relating thereto."

The general prohibition against communicating any "operations or processes of the Syndicate, or any of the affairs of the Syndicate or matters relating thereto," is ineffective, and can impose no restraints upon the engineer. Only secret processes of a valuable character will be regarded by the courts, and these only so long as the Syndicate can prevent publication. See American Stay Co. v. Delaney (Mass.) 97 N.E. 911. With respect to such processes as the Syndicate may successfully keep concealed, and while concealed, there would be an undoubted right to an injunction prohibiting publication by the engineer who enters into the relation contemplated by the contract, extraordinary and oppressive though the relation is; but, as intimated, the duty of the engineer in this regard would cease as soon as information respecting the particular process should have leaked into public channels.

The provisions of the agreement covering the case of inventions by the engineer rest on a different principle, nowhere better stated than by Mr. Justice Bradley in Aspinwall Manufacturing Co. v. Gill, 32 Fed. 697, as follows:

"A naked assignment or agreement to assign, in gross, a man's future labors as an author or inventor,—in other words, a mortgage on a man's brain, to bind all its future products,—does not address itself favorably to our consideration * * * Where the inventor is connected in business with the party making such stipulation, or is interested in the profits arising from the business in which the invention is used, the arrangement seems to be altogether unobjectionable. But such a connection or interest does not seem to be necessary to the validity of such bargains. If based upon a valuable consideration, they are sustained as collateral or incidental stipulations connected with the conveyances of a principal subject."

The present form of contract pretends that the principal subject is an employment of the engineer, and that the provisions as to assignment of inventions are collateral and incidental to such employment and for the proper protection of the employer. When, however, the agreement is scrutinized it is seen that the Syndicate need only keep the engineer "on its staff" "for such period as it deems advisable." Of course, the engineer can quit at any moment. There is no obligation on the part of either that the so-called employment shall last even for an hour. There is no salary provided, nor any agreed recompense. Yet, if the words of the contract be credited, in exchange for an illusory consideration named "knowledge and training" acquirable during "such period as" the Syndicate "deems advisable to that end," and of which, if and when acquired, no beneficial use will be permitted, the engineer undertakes onerous obligations and forfeits the freedom of his professional life.

It is my conclusion that, in this respect, the agreement would be held to be without valuable consideration and unconscionable.

C. Irving Wright.

San Francisco, December 18.

Gold and Silver Production of the United States

The Bureau of the Mint and the Geological Survey have issued the following joint statement as to the preliminary estimate of the production of gold and silver in the United States during the calendar year 1915:

State or territory.	Gold. Fine oz.	Gold. Value.	Silver. Fine oz.
Alabama	247	$ 5,100	.....
Alaska	804,317	16,626,700	838,100
Arizona	198,695	4,107,400	5,078,100
California	1,112,906	23,005,800	2,110,900
Colorado	1,073,499	22,191,200	7,395,100
Georgia	1,176	24,300	100
Idaho	50,726	1,048,600	10,595,300
Illinois	.....	.....	2,200
Maryland	19	400	100
Michigan	.....	.....	195,400
Missouri	.....	.....	56,400
Montana	230,415	4,763,100	12,690,200
Nevada	547,349	11,314,700	13,793,000
New Mexico	69,176	1,430,000	1,907,100
North Carolina	7,416	153,300	1,400
Oregon	84,144	1,739,400	126,500
Philippine Islands	62,259	1,287,000	14,500
Porto Rico	4	100	.....
South Carolina	101	2,100	.....
South Dakota	357,850	7,397,400	195,400
Tennessee	406	8,400	141,000
Texas	135,000	2,800	720,400
Utah	169,061	3,494,800	11,168,500
Virginia	53	1,100	1,100
Washington	12,926	267,200	154,000
Wyoming	977	20,200	700
Total	4,783,857	$98,891,100	67,485,500

These figures compare with the production of 1914: $94,531,800 in gold and 72,455,100 fine ounces of silver, being a gain in the gold production of $4,359,300 and a loss in the silver product of 4,969,500 fine ounces.

At a lumber camp in the Northwest, it was suggested that a lot of sanitary drinking-cups be ordered. "Good idee," said the camp boss, "we'll git some o' thim kind o' cups right away, and while we're about it we'll git a gross o' medicine-droppers so's the min kin use 'em to spit on their hands."

The Washoe Reduction Works, Anaconda—I

By L. S. Austin

This great metallurgical establishment, known locally as "the smelter on the hill," is 2½ miles from the neat and compact town of Anaconda, where everyone lives, since there is no settlement near the works. The company's street-car line transports most of its 3600 men day and night, thus providing for the transfer of the three shifts to and fro, between the town and the smelter.

The site containing the works is on a side-hill sloping in conoidal form from the main brick stack at the apex of the hill to the north and north-east. The main flue may be regarded as its back-bone, while the high-line and main-line tracks follow the contour of the hill, thus revealing its shape. The base of the main stack is 780 ft. above the floor of the lowest structure, the converter building, and this in turn is 100 ft. above the railroad situated on the flat below. It is this flat that has afforded a dumping-ground for the last 13 years and will clearly serve for another generation. Already the nearby ground is piled high and the main-line railroad runs through it as through a cut. The tailing and the slag (all granulated) are laundered to the dump.

When the works were first constructed in 1902, the general plan of treatment was thus elaborated:

The ore, a complex sulphide, was divided into 'first-class' and 'concentrating,' principally the latter. The concentrating mill yielded a coarse concentrate, which was sent to the blast-furnace, and a fine product for roasting and reverberatory smelting. The first-class ore was screened to give a coarse product suitable for the blast-furnaces, while the first-class fine, mixed with pond-slime, was briquetted, and also delivered to the blast. Both blast and reverberatory furnaces yielded a matte of 40% and over in copper, and this was blown to blister copper at the converter plant.

The general plan has been altered in detail, for the following reasons:

At the beginning, the first-class ore contained 8% or more of copper and the concentrating ore 4%. But, as smelting was cheapened by improved practice, a lower-grade ore became profitable. Thus great masses of ore, formerly left in the stopes, or revealed by development, became available; and it was seen that the life of the mines could be indefinitely extended. The first-class ore was lowered to 5%, the concentrating ore to 3%, in copper. Nor was this all: progress had been made in cheapening operating methods until it seemed that these had been cut to the minimum. But, for the purpose of obtaining high recoveries, new methods are constantly being introduced. Where before a 75% recovery in ore-dressing was painfully attained, now, thanks to round-table work, and particularly to leaching and flotation methods, this is approaching 85 to 90% of the copper entering the mill. To be sure this has called for the investment of millions in new installations and the cost of more operating equipment, but, on the other hand, it has been justified by the greater savings and the increased capacity of the works.

Referring to the general plan, it will be noted that the high-line tracks coming from Butte enter the north corner and follow the contour of the hill. Branches from this line are carried on a high trestle to connect both the sampling-mill and the concentrator, the latter being hung upon the steep hill-side, so that the ore may proceed from machine to machine by gravity. Trains of 75 cars, each of 50 tons, deliver the ore from the mines at Butte.

The main-line tracks enter from the same direction, the cars delivering ore, limestone, and fuel to the blast-furnace storage-bins. Brick, machinery, sand, lime, acid, and other supplies from the flat below enter by these same tracks. Altogether this railroad system supplies 20,000 tons of material daily.

Besides this there is the yard system for moving materials from point to point. It is handling fully 16,000 tons daily. The blast-furnace charges, the concentrate from the concentrate-dewatering plant to the roasters, the calcine for the reverberatories, the matte to the converter plant are moved about by compressed-air locomotives in trains of 5-ton cars and the matte in 10-ton ladles.

The supply of water comes from Warm Springs creek and is carried 7 miles by flume to the smelter. Part of the supply in winter is pumped over a ridge to the creek from the Silver Lake storage-reservoir, 15 miles west of Anaconda. At the flume-house movable screens are provided to remove leaves, etc., before the water goes to the supply-tanks. This means that a man is on guard on each of three shifts.

The concentrator plant has eight units, four in each building, but the lower portion adjoining the tank-house is being altered, unit by unit, for re-grinding and flotation treatment. The difference of level between the high-line track to the concentrator and the main-track into the works is about 125 ft. Below the concentrator, and adjoining the main track, nine new buildings are situated. Elsewhere are the ore-driers at the east end of the roaster building, the coal-pulverizing plant and its adjuncts at the end of the reverberatory building and the boilers and stack for No. 9 reverberatory furnace at the west end of the converter building. Besides the office-buildings are the supply buildings and several repair shops.

A mile away from the works and toward town the company has erected its acid plant and a new brick plant. In the same locality the company has a large foundry

and machine shop, where new parts and some repairs are made both for the Washoe works and for the mines.

Just at present the original material entering the works includes 13,500 tons of ore, 500 tons of coke, 550 tons of coal, and 1150 tons of lime rock; in all, 16,000 tons. With all the new construction, the pay roll includes 3600 men, of whom 2100 are now actually engaged in the operation of the works, on 8-hour shifts.

Quick Repair of Main Flue

In 1911 some 80 ft. of the single flue collapsed at

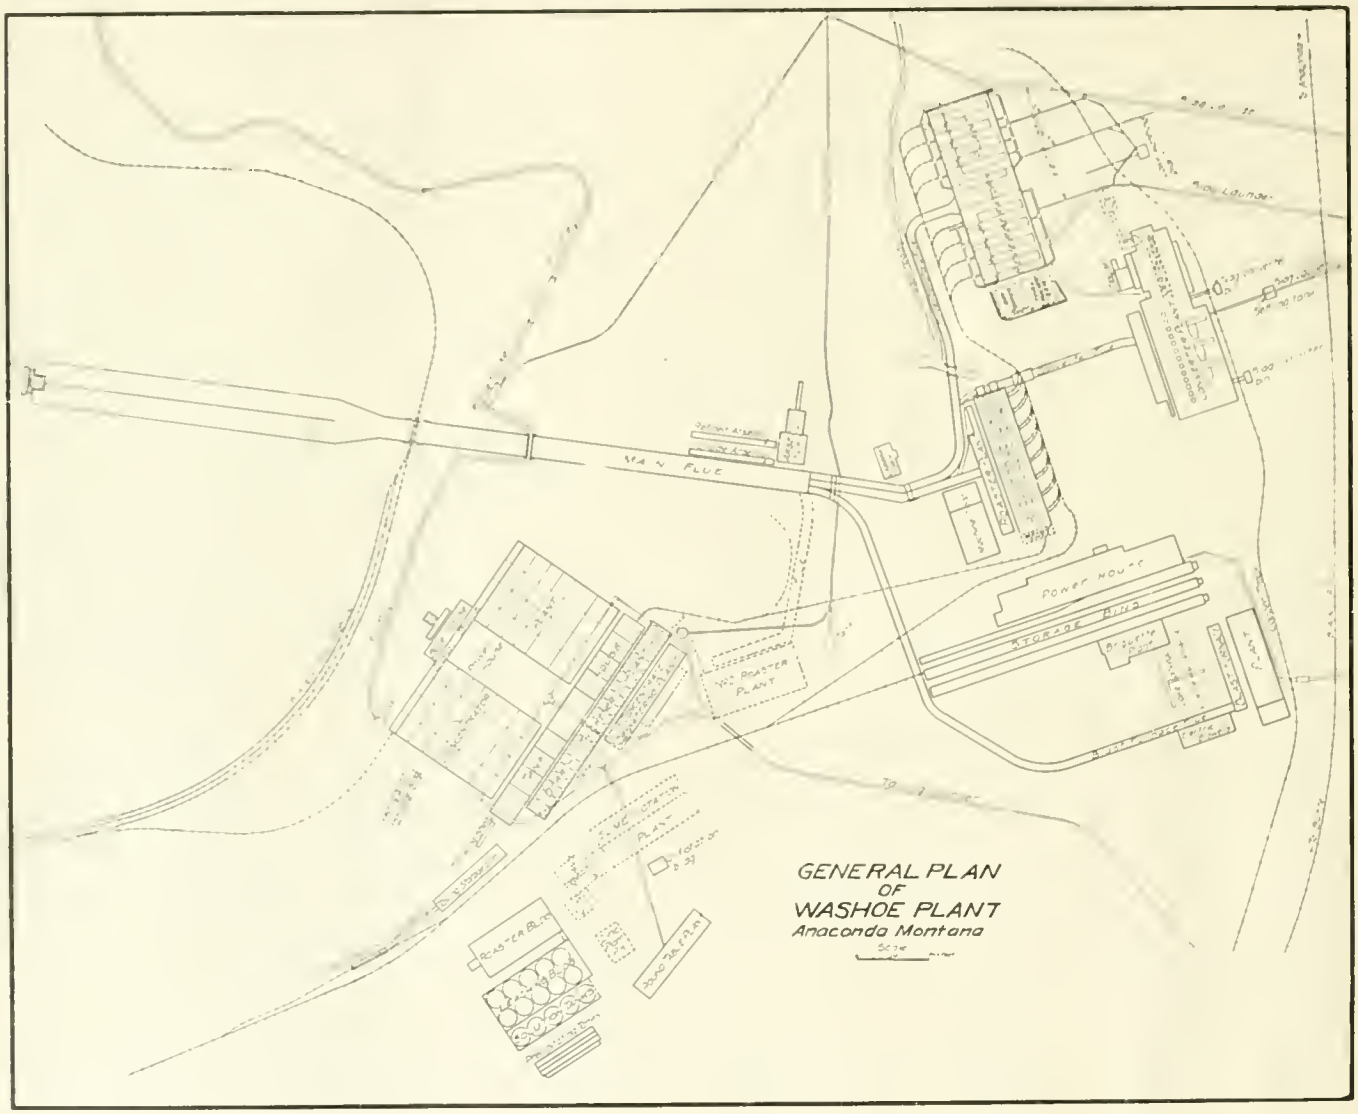


Fig. 1.

4 p.m. The works were shut-down and the repair-gang worked interruptedly until 8 p.m. the following night, when the furnaces were again started. This involved the speedy ventilation of the flue, the removal of the ruined structural steel and brick-work, the re-building of the upper portion of the brick side-walls, the placing of new beams and of the brick roof over an area of 60 by 80 ft. The acetylene flame was used in cutting the steel beams for speedy removal. To prevent the recurrence of such a disaster the single flue is held up from end to end by transverse trusses spaced on 20-ft. intervals. The single flue with its trusses, the double flue, and the stack are shown in the photograph, Fig. 2. The trusses are carried independently of the side-walls upon latticed posts that just clear the wall outside. The trusses support longitudinal channels, which, in turn, are tied to the transverse rails. These rails serve as skew backs for jack-arches of 3 ft. span.

The No. 2 Roaster Plant

To roast the increased tonnage of sulphides, due to the installation of flotation methods of concentration, a new roaster plant is being built rapidly with a view to its completion by the end of the year 1915. At the same time the smaller reverberatory furnaces are being enlarged, other 20-ft. converters installed, and No. 9 reverberatory added at the end of the converter building, all to take care of the expected increased production of concentrate.

This No. 2 roaster plant is close to the 'concentrate dewatering plant' and parallel with the main trackage of this part of the works (see Fig. 1). It contains four rows of roasting-furnaces, seven in a row, or 28 in all.

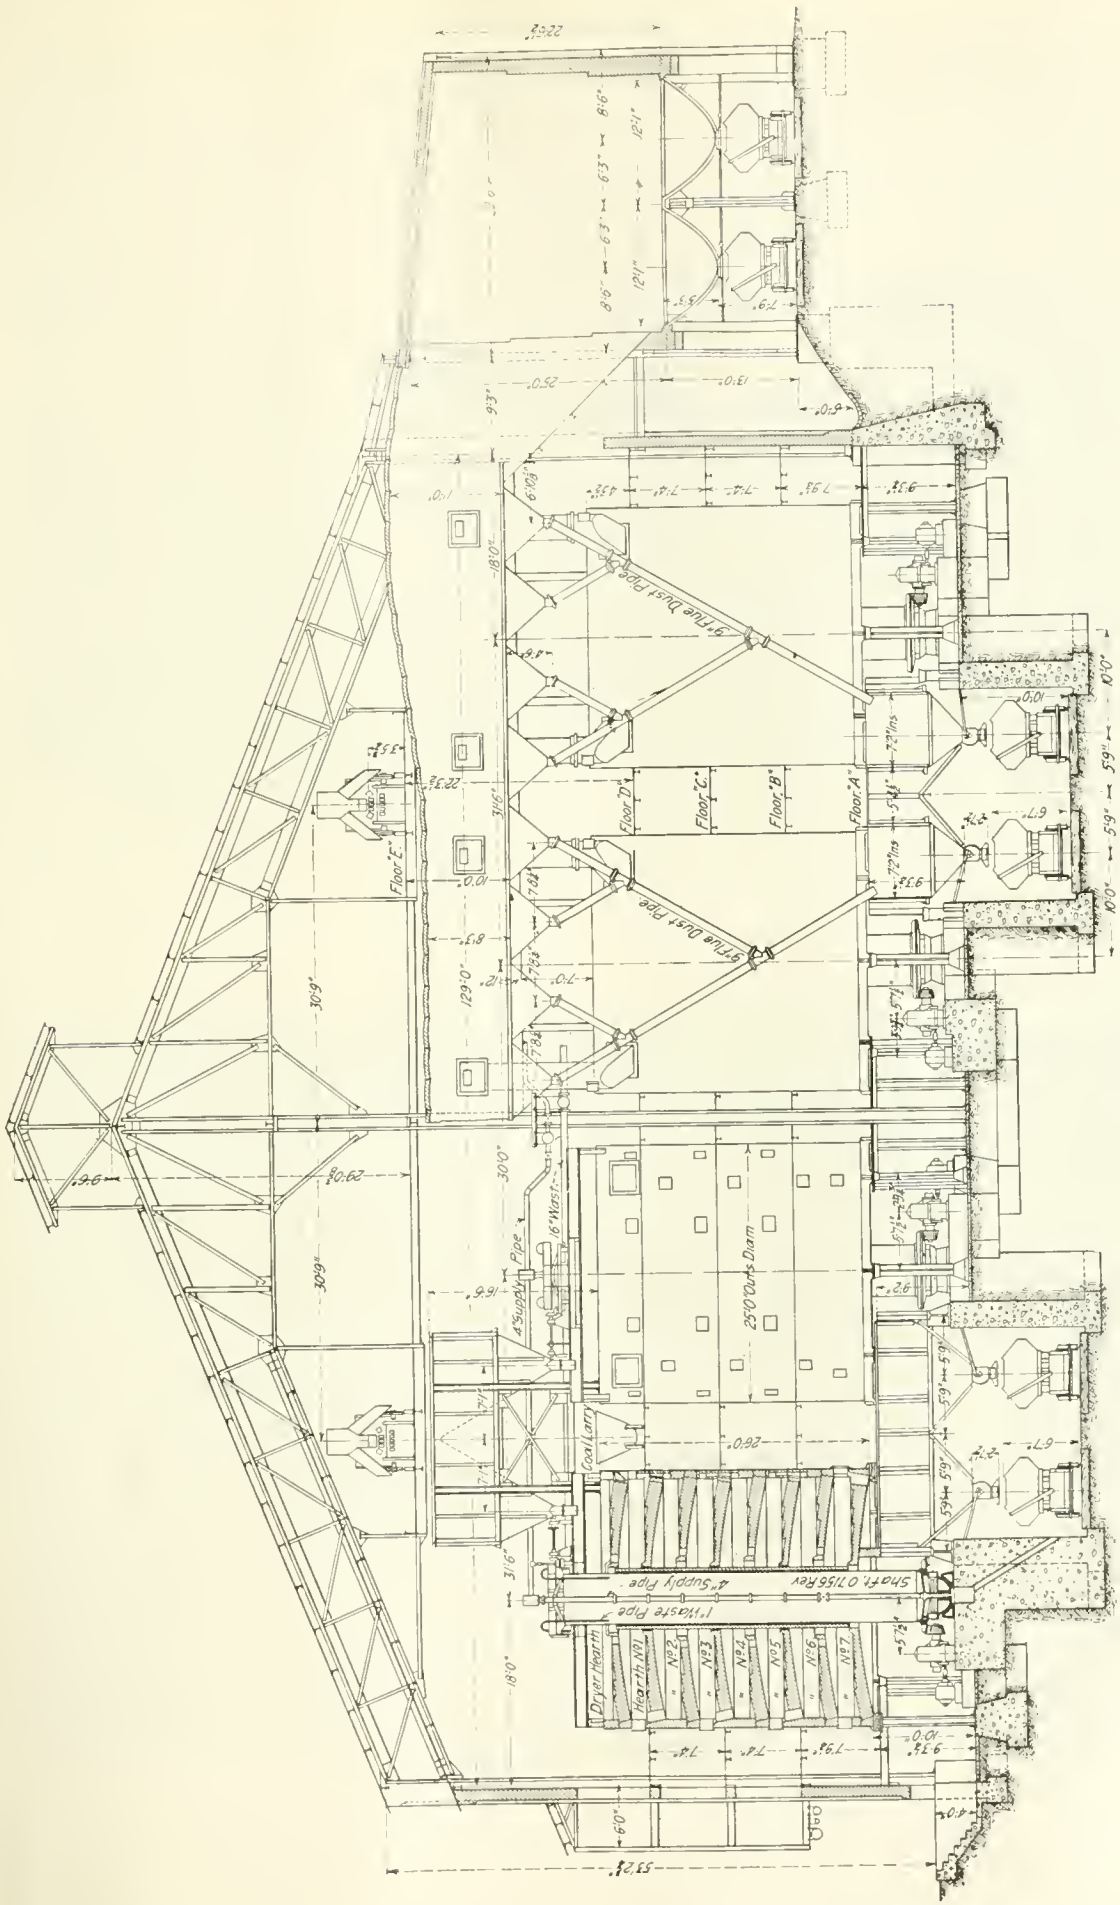

FIG. 3. TRANSVERSE SECTION OF ROASTER PLANT.

These have a shell diameter of 25 ft. and are 23½ ft. inside diameter, each roaster having seven hearths.

In Fig. 3 is given a transverse elevation of the building, which is 129 ft. wide by 270 ft. long. The draft-gases from each nest of eight furnaces are carried off by a transverse flue, of which there are four in all. These flues, 8 ft. high by 10 ft. wide, will deliver to a flue 28 ft. wide by 24 ft. high and this again leads to the foot of the main flue of the works. A row of hopper-bottom storage-bins, set transversely at the south end of the building, but not shown in Fig. 3, receives concentrate from cars on a track that runs over them. The concentrate may be drawn from any storage-bin upon a 24-in. conveying-belt, thence west by an inclined conveying-belt to a chute at the other end. This chute delivers to another inclined conveyor traveling the opposite way, and running horizontally across the roaster building within the roof-structure, and high enough to deliver its load to either of the longitudinal troughed belt-conveyors shown in Fig. 3. Each of these conveyors has its own tripper, so that the concentrate can be delivered to any roaster-hopper desired. Contrast this with the method pursued at the older, No. 1 roaster building, where the same material is brought in by train-load upon an overhead track, so that a heavy structure is needed to sustain the train.

Both the cross-flues and the roaster-flue have hopper-bottoms. Pipes carry the flue-dust from the cross-flues to the furnace-discharge hoppers while the contents of the roaster-flue are drawn off periodically into cars.

Studying the roaster itself, which is of a MacDougall-Wedge type,* one notes that the top of the furnace is a drying-hearth, while there are seven others with central and side drop-holes or openings in accord with the Wedge system. The draft passes away at the side by four off-takes at No. 1 hearth-level, rather than at the top as in the MacDougall furnace. These liberal exits tend to lessen flue-dust loss.

The arms and the 5-ft. central shaft may be cooled by either air or water. This central shaft is entered by a man-hole at the side. The outside of the shaft, to protect it from the heat, is lined with tile as in the Wedge roaster. The shaft with its stirrer-arms is carried by four rollers, and is driven with spur-gear and pinion by an electric motor.

A novel feature of the building is that the four working-floors are carried outside the sides of the building and around the furnaces, so that access to any furnace is obtained by a well ventilated passage. Coal is raised in an elevator to the upper floor (and distributed to the different furnaces by means of a larry) for use in starting or in warming up as may be needed, though the concentrate has enough sulphur to be self-burning.

Altogether the building, flues, and furnaces show good design and thorough construction, the result of long experience in the older part of the plant.

*The rights for the use of the patented features of the Wedge roaster have been purchased by the company for a lump sum, and these have been incorporated into this furnace.

Coal-Dust Fired Reverberatories

Referring to the general plan of the works, Fig. 1, the reverberatory plant contains eight furnaces, numbered consecutively from the west to the east of the building. The large reverberatory at the west end of the converter building is called No. 9. Number 8 furnace was the first one altered to coal-dust firing, being extended to 124 ft. long, but retaining the old width of 20 ft. Reverberatories No. 1 to 7 inclusive have been, or are being, altered to approximately 144 ft. long by 23 ft. wide, and, in part, are now in successful operation.

Reverberatory No. 7 (see Fig. 7) is typical of the new furnaces, the plans having been completed after the testing of No. 8 on coal-dust firing. It is 143 ft. 2 in. long by 23 ft. 4 in. wide. The roof, 9 ft. 6 in. high at the fire-end, maintains that height half-way along the furnace, then slopes gradually to 6 ft. 6 in. at the front. The arch has a rise of 2 ft. 5 in. (1½ in. per ft.) It is a question whether the roof in the hottest zone should not be still higher, both as lessening the thrust on the skew-backs and of removing it from the close contact of the flame. This was an idea on which Siemens insisted in the construction of the open-hearth furnace. The spring of the arch is supported by a built-up channel wide enough to receive the skew-brick. These channels also serve as longitudinal ties. At the firing-end the arch-bricks are 25 in. at the spring, and 20 in. at the crown of the arch. This arrangement continues for one fourth the length of the furnace, dropping then to 20 in., and finally to 15 in. for the thickness at the front. Transverse joints in the roof, 3 in. wide and every 20 ft., allow for expansion as the furnace is heated. The last joint is but 5 ft. from the end of the roof at the verb, and makes, with the horizontal arched front edge, a structural feature worthy of note. See Fig. 5.

At the front, 3 ft. 3 in. to the left of the centre line, comes the matte-tap placed at the hearth-level, and 24 in. above at 2 ft. 9 in. to the right is the dam-plate of the slag-tap. On an output for the furnace of 600 to 700 tons per day there results a steady flow of slag over the dam-plate. Matte is tapped on an average about once in two hours, but actually, according to the demands of the converting department, which may withdraw several ladlesful in succession. The flue-bottoms converge to the tap-holes. There are two flues, each 6 ft. by 8 ft., dampered in order to regulate the draft exactly. Thus the gases may be thrown to either of the waste-heat boilers, right or left. Each stack of boilers consists of two, each 300 hp., placed in series. No. 9 furnace at the converter building has its boilers in parallel, thus obstructing the draft less, and either of them may be by-passed while the other still operates; but then the gases pass to an independent steel stack 200 ft. high.

At the firing-end are the five coal-dust burners fed from a hopper-bottom bin of 63 tons capacity (Fig. 4). The coal-dust withdrawn from the bin is fed by a screw to four 1-in. drop-pipes, and falls into the burner-

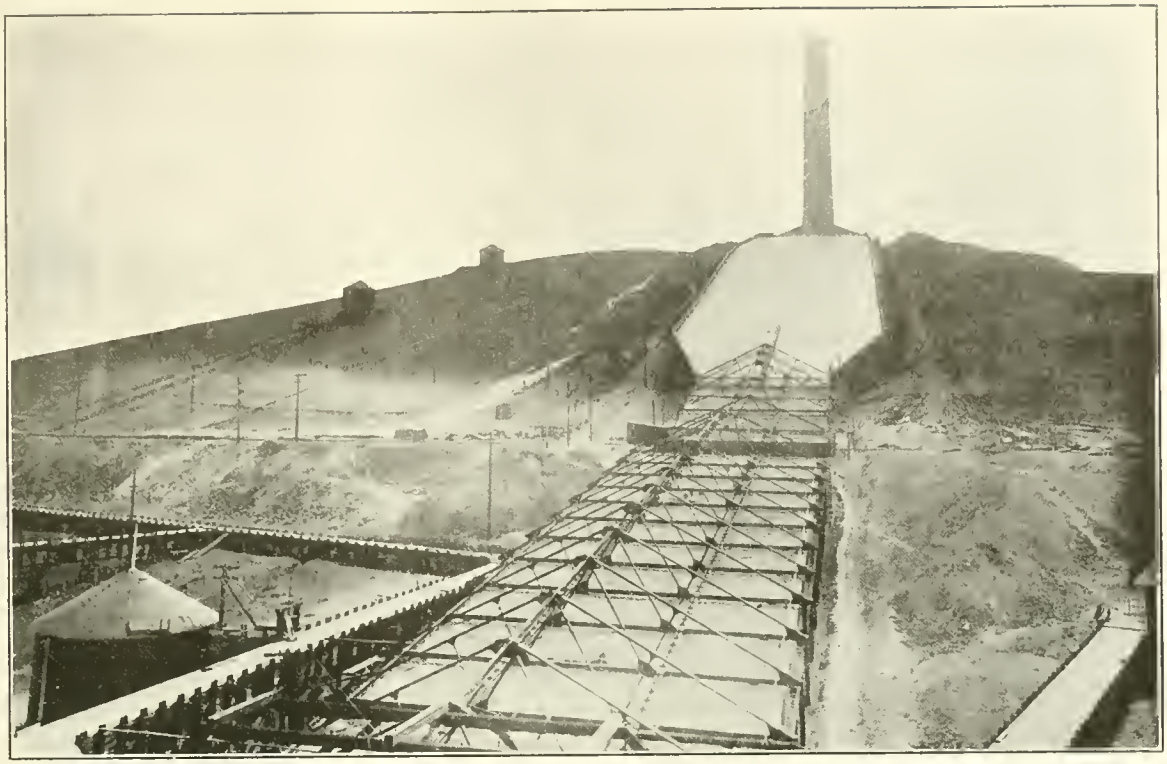

FIG. 2. THE MAIN FLUE AND STACK. THE SINGLE OR 60-FT. FLUE IN THE FOREGROUND HAS A TRUSSED ROOF. THE DOUBLE OR 120-FT. FLUE HAS A PLATE-IRON ROOF. THE STACK IS 30 FT. DIAM. BY 300 FT. HIGH.

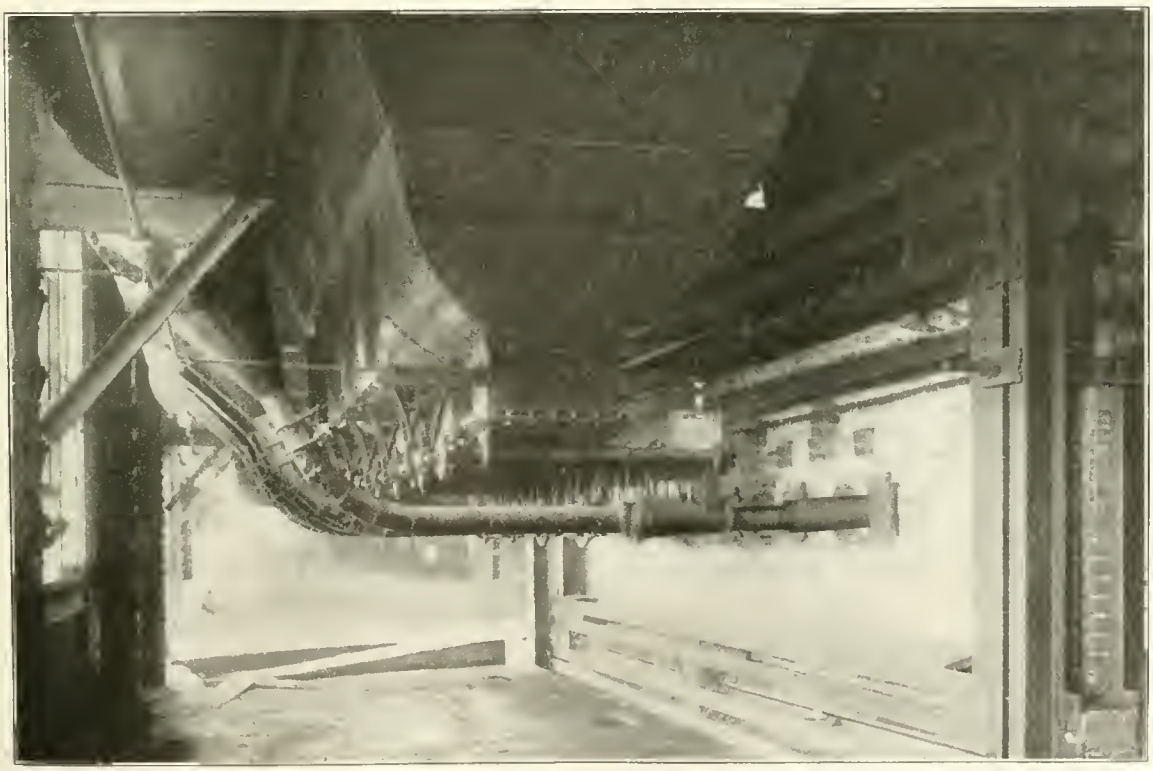

FIG. 4. THE COAL-DUST BURNERS. AT THE LEFT THE HOPPER BOTTOM PULVERIZED COAL FEED-BIN. FROM IT LEAD FIVE BLOW-PIPES, WHICH ENTER THE BACK WALL OF THE REVERBERATORY FURNACE. ABOVE THESE PIPES ARE SEEN THE SCREW-FEEDERS, ONE TO EACH PIPE, BY WHICH THE COAL DUST IS FED.

pipe, where it is injected into the furnace by means of pressure of air from the 30-in. air-pipe against the north wall of the building. There is a Reeves variable-speed belt-drive by which the coal-supply can be regulated. To supplement the injector supply, there is a secondary air-admission at the drop-pipes, another at the tapered injector, and a third regulated by a slide on each side of the burner-pipe where it enters the furnace. Thus, both coal and air, conjoined to damper regulation, ensure efficient burning of the coal. The draft pressure is watched, and constant gas-analyses made to make sure of complete combustion.

There are two feed-bins, one on each side; also a transverse feed-bin at the firing-end. From these bins come down the feed-pipes set at 26-in. centres. Each feed-pipe has its own slide-valve. The pipe bends just before it enters the furnace; and here a peep-hole enables the condition and height of the charge within the furnace to be known. Above the furnace are two parallel tracks where the trains of charge-cars enter. It is at the first and hottest half of the furnace that most of the charge is smelted, and it is accordingly at this point of the furnace that the hoppers must be most frequently replenished. The feed-pipes near the front deliver siliceous ore from the hoppers into the furnace for fettling purposes only.

Fig. 6 gives a longitudinal section and the heat-intensity curves progressively from the firing-end, taken in February 1915. It will be seen that a properly regulated supply of air lengthens the smelting zone and slightly increases the final temperature of the furnace. It is possible, by increasing the supply of fuel and air, to urge the furnace so that the roof will be melted, and this is one of the limitations to capacity. If we take the formation temperature of slag at 1100° C., the final furnace-temperature is well above it. There is no fear of the slag setting or solidifying as in a grate-fired furnace using natural draft. Where, using solid coal, a draft of 1.7 in. water was required under coal-firing, 0.10 to 0.15 in. is now enough, that is, to remove the products of combustion. Corrosion of the brick-work takes place chiefly in the hottest zone, that is from 20 to 60 ft. from the firing-end, both roof and side-wall being invaded. At the side-wall the bricks may be driven in and the opening newly bricked up. Once in about seven months a more serious repair is needed, since the roof near its spring has been eaten away.

Diamondville coal, dried and powdered, is used. It has the following composition:

	%
Moisture	1
Volatile combustible matter	40
Fixed carbon	48
Ash	11
Calorific power	6775 Cal.

With the air 52% in excess, the intensity of the flame was more localized and the CO_2 was lower, indicating less perfect combustion. When the air exceeded the theoretical amount by 15% only, then the heat-zone was more extended, the CO_2 going to 16%, but this was done with a higher draft. In present practice the average of the gases gives: CO_2, 19.2%; CO, 3%; and O, only 0.2%; hydrogen is not determined. The gas analyses are constantly made, and the working of the furnaces controlled by them; besides the regular determinations, a Simmons-Abady apparatus automatically registers the amount of CO_2 in the gases. A constant gas supply is drawn from near the front end, a few inches below the roof, through a laboratory-size centrifugal fan, and from this the apparatus takes what it needs. It will be seen from the analysis that the combustion is nearly perfect and that there can be but little excess air.

To give an idea of the performance of these furnaces, let us take an ordinary 24-hour record:

	Tons.
Smelted calcine	579.8
McDougall flue-dust	6.7
Main-flue, flue-dust	46.2
Blast-furnace flue-dust	43.6
Total charge smelted	676.3
Total pulverized coal used	103.4

Ratio, one of coal to 6.54 of charge, equivalent to 15.3%. One may note the large amount of flue-dust, which is less easily smelted than the hot calcine.

The No. 9 Coal-Dust Fired Reverberatory

This furnace is situated at the west end of the converter-plant and has its own blowers, waste-heat boilers, flue, and independent stack.

Inside dimensions of the furnace are 153 ft. by 20 ft. 6 in., smaller than the regular type, but large enough for its special duty. It is intended for smelting some 1200 tons of molten converter-slag daily, besides calcine, and also raw sulphides for cleaning the copper out of the slag. Pieces of ladle-skulls, sweepings, spilled slag, refining-furnace slag, matte, and other material from the converter-plant are treated. It is probable, however, that the solid material may have to be crushed and fed from the side-hoppers. I may add that this furnace has two rows of side-hoppers for charging calcine and ore, also a centre row to be used in the same way, when found advisable. The large amount of molten slag should create so large a bath that central charging can be performed, especially with fine calcine, which spreads when dropped, flowing like water on the molten surface of the slag. In No. 8, the 20 by 124-ft. furnace, this was tried, but owing to the piling up of calcine at the walls and the leaving of a trough in the centre, this central space was obstructed, and so the matte was dammed back from the tap-hole. Between the two sections of central hoppers is a 3-ft. diam. opening intended for charging ladle-skulls and other pieces, this hole being closed by a brick cover.

The furnace is so placed that there is plenty of room on the converter side for charging cranes and handling ladles. There are two tap-holes for the matte, respectively 25 and 30 ft. from the front, with launders leading to the ladle in the pit. For charging on the same side there are provided three slag-openings having brick-lined lifting-doors, situated respectively 21, 30, and 39 ft. from

FIG. 5. FRONT END OF NO. 6 REVERBERATORY FURNACE. THE INDEPENDENT VERB ARCH IS SHOWN, SEPARATED BY A 4-INCH JOINT FROM THE REST OF THE ROOF. THIS JOINT CLOSES BY EXPANSION WHEN THE FURNACE IS HOT. BETWEEN THE MEN IS THE SLAG-HOLE OR SKIMMING-HOLE.

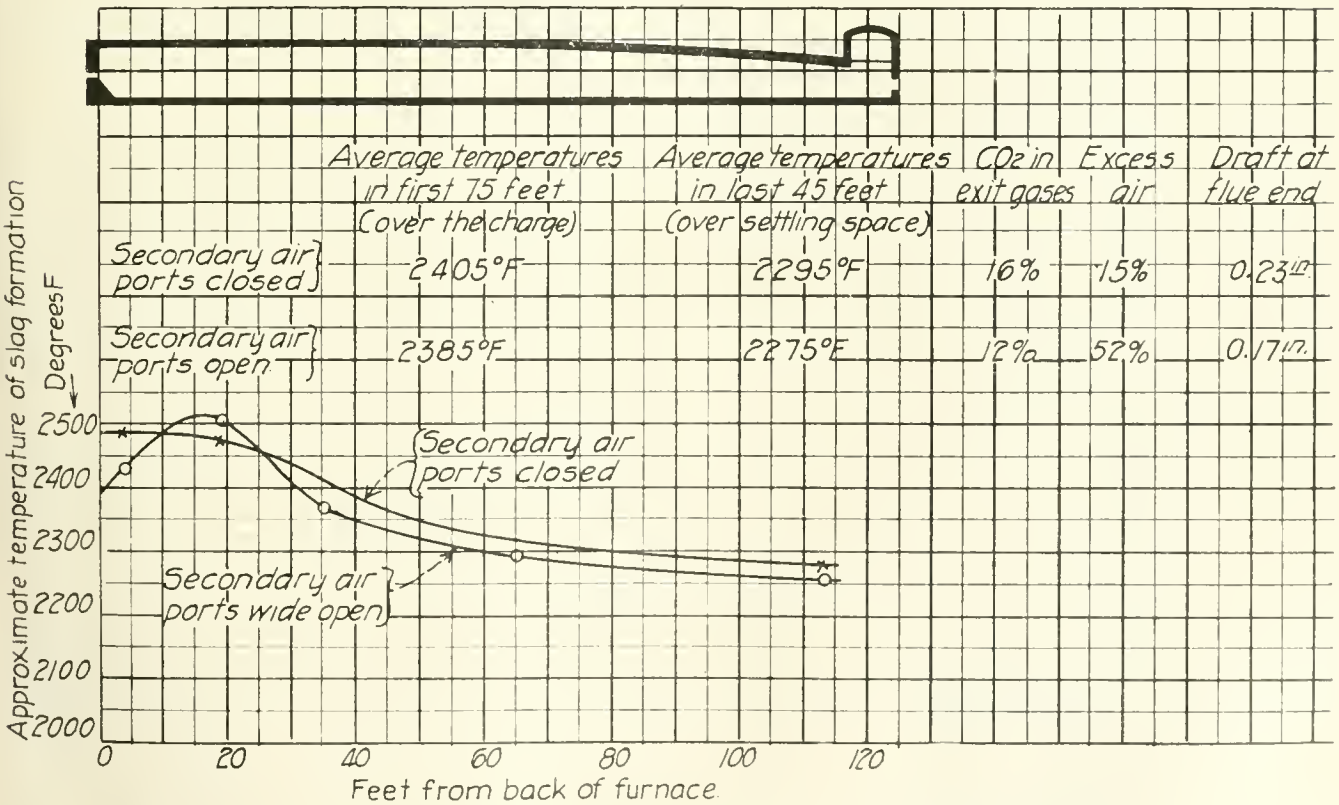

FIG. 6. TEMPERATURES AND GAS ANALYSES IN NO. 8 REVERBERATORY FURNACE.

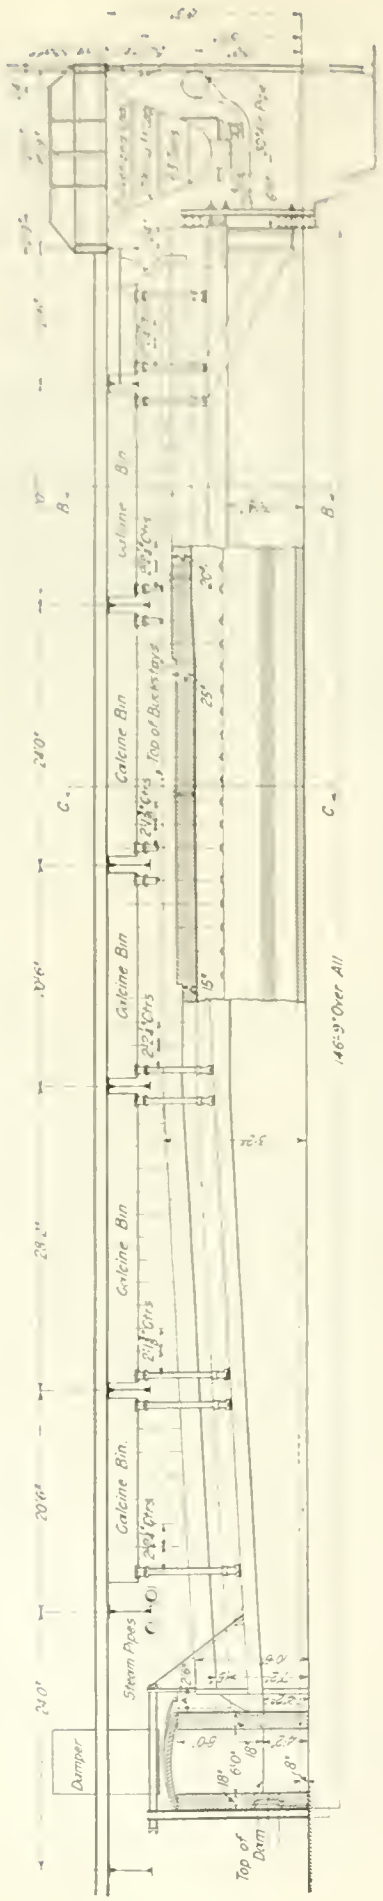

Fig. 7. Longitudinal Section of Reverberatory Furnace

the firing end. Slag is to be charged through any one of these openings by means of any one of three funnel carriages mounted on wheels, and shown in detail in Fig. 8. This four-wheeled carriage may be advanced or withdrawn as desired on a short standard-gauge track, so that immediately after charging, it can be run back and the door of the slag-opening closed. It carries a cast-iron lined funnel of 5 ft. diam. with a curved spout for directing the stream of slag into the furnace when in charging position. Molten slag from the converter is poured into the funnel from the crane-ladle. Two openings are provided at the front of the furnace, the higher one being the slag-opening with its skim-plate, the other a tap-hole at the floor either for draining the furnace or, if desired, to be used as another matte-tap.

The front end is tied centrally to the skew-back side-

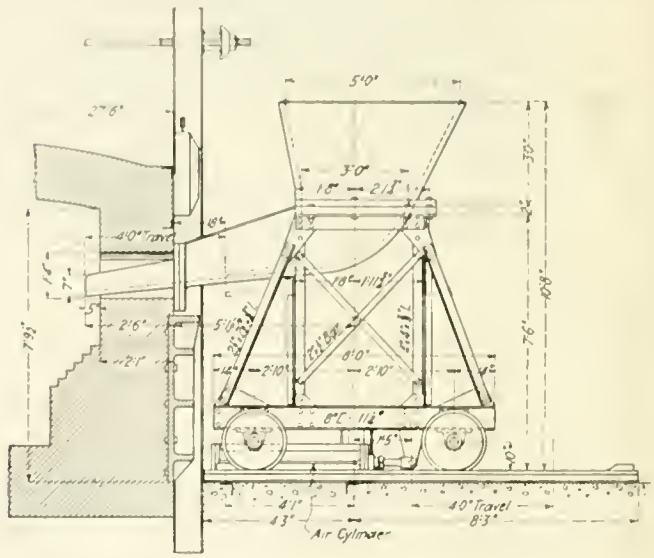

Fig. 8.

channels, which also tie the adjacent sides, as shown in the longitudinal plan. At the firing end is an inclined channel that ties the skew-back channel strongly to that end. The side-walls have concrete foundations, and the bottom will be of crushed quartz melted in. The roof has the same substantial construction as the standard furnace, being 25 in. thick at the haunches at the firing-end, 20 in. thick at the centre, and thinning to 15 in. at the front.

Since this furnace has never been thoroughly tested, openings have been made, so that any desired procedure may be adapted, until experience has shown the best methods of operation. The furnace seems to have many judiciously-planned and convenient features.

The flue itself is 8 by 6 ft. wide, enlarging toward the two boilers of 300 hp., each set in parallel, so as to afford less resistance to draft. It cannot be seen that provision for damper has been made. Older practice with a single stack places it at the top of the stack. The stack itself (unlined) is 8 ft. diam. by 200 ft. high.

The Coal-Pulverizing Plant

To supply 100 tons per day of pulverized coal to each of nine reverberatory furnaces requires a large equip-

ment. The plant is placed, as may be seen, on the map, Fig. 1, at the east end of the reverberatory-building. A gallery, extending the whole length of the north side of the building, shelters the long conveyor that delivers the coal-dust to the bins of each furnace. A bridge from the coal-pulverizing house northward performs the same duty for the conveyor to No. 9 reverberatory at the west end of the converter building.

Briefly, the run-of-mine coal to be pulverized is coarse-crushed, dried, pulverized, and delivered to the feed-hoppers of the reverberatories. Use is made of the conveying-belt at first, but the screw-conveyor is the principal method of transfer.

The coal comes in hopper-bottom cars by overhead track above a 60-ton steel receiving-bin. From this it is drawn into a Blake crusher, then by a vertical elevator and a 36-in. horizontal belt-conveyor to any desired part of a 1000-ton storage-bin. When wanted for use this stored coal can be drawn off upon a 24-in. conveying-belt, thence by another belt-conveyor into the plant. Often coal from the crusher drops at once on this conveyor. The head end of the conveyor has a Dings magnetic pulley, which removes any iron or steel particles from the coal.

At this point a vertical elevator delivers by chute into No. 1 dryer, and by a 14-in. horizontal helicoid conveyor into No. 2 and 3 dryers. The dryers are of the Ruggles-Coles type, 6 ft. diam. by 40 ft. long, with inner and outer concentric cylinders, and at the fire-box end a suction-fan for the removal of the fire-gases, and incidentally a little coal-dust. The dried coal, containing less than 1% moisture, falls from the drier upon disintegrating rolls, where it is reduced to grain size. This time it is sent back to the higher 'No. 2 Elevator' for delivery to what may be termed a main-line conveyor leading over into the Raymond pulverizer-building. Transverse to this and extending the length of the pulverizer-building are two horizontal helicoid conveyors, right-hand from the main conveyor in one direction, left-hand in the other. Thus there is delivery to any of the 10 feed-hoppers on both sides of the building, these feed-hoppers supplying the ten 5-roller Raymond mills. This type of mill has its rollers hung on vertical shafts that carry the rollers around in contact with a die-ring as in a Huntington mill. The finely pulverized coal becomes so light that, separating from the coarser product, it can be drawn upward by an exhaust-fan, the material from any mill entering its own 7-ft. cyclone collector. In this collector the pipe enters tangentially and the dust, striking the walls, falls into the cone-shaped bottom, while the air, now measurably free from dust, is returned to the mill, thus completing its closed circuit. From the curved summits of the return air-pipes vertical branches rise to the 4-ft. auxiliary collectors, affording relief to the air drawn in at various joints of the Raymond mills. From the outlet-pipes of the auxiliary collectors may be noticed a thin cloud of coal-dust too fine for settlement. It is at the point of the 7-ft. cones that we have another helicoid conveyor, this time transferring the dust to the west end of the building, and another transverse one taking the dust north to the gallery of the reverberatory-building already mentioned. It is along this gallery that extends a final helicoid conveyor supplying the reverberatory hoppers.

Counting to the fourth collector from the east end, there is a 6-in. right-hand helicoid conveyor, which can get its coal-dust from the 14 in. one above it, simply by opening a slide. The 6-in. conveyor moves the dust to the east end of the building, where it drops into another transverse one running along the wall. Thus at will coal-dust can be supplied to any of the drier fire-boxes, though at present those boxes are fired by hand with run-of-mine coal.

Copper Production of the Large Mines

The following table, from the *Boston News Bureau*, shows the increased yield of some of the great mines of this country during the past year, figures for 1915 being in nearly every case the official estimate, and for 1914 they represent actual production (in pounds):

	1915.	1914.
Ahmeek	22,000,000	13,634,605
Allouez	10,000,000	6,056,548

Stamps and Competitive Machinery

By H. C. Cutler*

"If gold mill operators are prepared to abandon the use of the stamp as an amalgamating device, and will send the stamp mill pulp directly to the tube mills, passing the tube mill discharge over amalgamated plates before sending it to the cyanide plant, the question may be raised as to whether it is necessary to retain stamps for the preliminary crushing of the tube-mill feed. The verdict of experience seems to be that the tube-mill is an excellent crushing device to free gold from its adhering gangue, the impact of the pebbles furnishing a sufficiently heavy blow for the comparatively small particles with which the tube-mill is fed. The logic of the situation would then seem to be that the crushing of the tube-mill feed should be done by the most efficient machine or machines, regardless of their principle of crushing action. This scheme of milling is about to be put into practice in the new large mills of the Alaska Gold Mines and publication of the results of operations there will be awaited with the keenest interest by mill-operators elsewhere."

The above extract from an editorial in the MINING AND SCIENTIFIC PRESS, October 3, 1914, is indicative of the situation that has confronted the milling fraternity for some time past. In the course of a trip during the past summer to some of the large copper-concentrating plants, I could not help but be impressed with the methods and costs of reducing ore from mine-run size to tube-mill feed. Without doubt the copper metallurgists have something of an edge on the precious-metal mill-men in this stage of the crushing operation, and it occasions no surprise that when a metallurgist conversant with these methods goes into gold-milling on a large scale, as has D. C. Jackling at the Alaska Gold Mines, he should use the methods by which he has been able to obtain such small costs in the reduction of copper ores. Just why the gold and silver mill-men have adhered to the use of stamps as a means of comminution in stage-reduction, especially when used to produce a product as large as 4-mesh, is hard to see, in the face of a comparison of costs with other methods. Granting that it is done, stamps must possess some advantage over other types of machinery to warrant their continued use, unless we are to make the claim that it is all a matter of prejudice. The main claims for preference as given by one operator who still persists in using stamps are as follows:

"Stamps are flexible: By a change of screens, height of discharge, and other adjustments, the product can be varied from very fine material to as coarse as desired. Stamps are obtainable in small units, each unit as efficient as another, so that the total capacity can be increased cheaply and easily by the addition of units. Stamps are practically fool-proof, simple in design and operation, and easy to transport. There are plenty of men skilled in their operation. Repairs are easy. In repairing it is necessary to shut-down only one unit at a time, thus not interfering with the operation of other portions of the mill. Stamps will operate on any kind of ore, wet, clayey, hard or soft, with very little change or adjustment. In addition, there is a certain advantage when used as an amalgamating device and especially when amalgamating inside the mortar."

In a number of places, doubtless, the advantages as outlined above would outweigh the claims of any other style of crusher. For a small mill, of, say, 50-ton capacity per day, using either straight amalgamation or a combination of processes, especially where first cost is an item, there is probably no other single machine as efficient, but in larger units than this, even where amalgamation is used, and in mills where stamps are employed as intermediate crushers, their cost of operation is higher and their efficiency less than several other machines on the market.

Stamps were among the earliest of machines used in America for the reduction of gold and silver ores and they did the work without trouble. At first, however, the ores handled were usually of high grade so that a few cents more in the cost of reduction made but little difference, and in the case of a question as to the choice of crushing machinery, it is a matter of common knowledge that operators generally stick to what they are accustomed and know will do the work. This accounts for a good many installations of stamps.

With the development of the 'porphyry' copper mines, with their hugh bodies of low-grade ore, the reduction of a large tonnage at a minimum cost became imperative. Better and cheaper methods of reduction had to be used to make any profit at all, and stamps would not stand the competition. Cheaper methods were devised. As the number of mines containing bodies of high-grade gold and silver ores lessened, the lower-grade ores began to create more interest and the matter of costs of metal production assumed importance. At the present time a few cents difference in crushing costs is an item scrutinized with great care, and for this class of crushing, stamps are falling behind and will be used less and less.

In the work of coarse crushing that precedes stamps the cost has apparently reached a minimum without much chance of reduction. Run-of-mine ore has been crushed to $\frac{3}{4}$-in. size for less than three cents per ton with gyratories and disc-crushers, which is so low that the saving in costs must be made from this stage forward.

*Mining Engineer, Reno, Nevada.

The fineness required depends to a large degree upon the metallurgical process adopted in the extraction of the metals contained; again, upon the fineness required depends largely the choice of crushing machinery. The problem is to reduce the product of the coarse-crushing plant, say, a maximum of 1½-in. material, to the fineness best suited to metallurgical treatment.

For concentration of copper ores the size of this final product may vary, depending upon the size and character of the particles of mineral in the rock, and whether water concentration, oil flotation, leaching, or a combination of two or all is to be used. The same thing is true of gold and silver ores, the product desired depending almost entirely upon the character of the ore and the metallurgical process to be used. Before the introduction of the cyanide process, fine grinding was not in vogue, a 40-mesh product was considered adequate and it was for this class of work that the stamp-mill secured such a commanding position. This held true to a large extent during the time that the cyanide process was limited to percolation. When agitation with all-sliming was introduced, further grinding became necessary, and the tube-mill, which had been an efficient machine in the cement industry, was added as a finisher.

The 600-ton test-mill erected and run by the Inspiration Copper Co. attempted to solve some of the questions involved. The results desired were slightly different from those of most gold and silver mills. An ultimate product, all of which would pass 48-mesh was most suitable for subsequent treatment by flotation, while in cyanide work the finer the ultimate product the better, a product all of which approaches 200-mesh being desirable. H. Kenyon Burch had charge of the testing; he had an idea of obtaining a machine that would make the reduction from ¾-in. material to the desired 48-mesh in one operation, thus reducing floor-space, elevation, and subsequent attendance. A large number of machines of various kinds were tried and it appeared impossible to obtain one machine that would do this; so stage-crushing was adopted. The Symons horizontal 48-in. fine-disc was installed early and was a great success in reducing a maximum of 2½-in. material to 6-mesh. This feed was tried in Hardinge machines and tube-mills, but it seemed to increase their work out of proportion; hence intermediate crushers of various kinds were introduced in the circuit, taking the disc-discharge and effecting a reduction to 16-mesh, which seemed to be the best feed for the tube-mills. None of these intermediate machines was successful, and it appeared for a time as if the work would finally be done by the use of the Symons fine-disc and Hardinge pebble-mills. Almost at the last moment the Marcy ball-mill was installed, taking the product of the coarse-crusher plant and reducing to 48-mesh in the one mill, using a classifier and closed circuit. That this mill and its operation proved to be the most economical of the machines tested is evidenced by the fact that Marcy ball-mills were installed in the 10,000-ton mill.

It is claimed that the most desirable feed for the ball-mill is a mixed one, coarse and fine, the coarse material filling the spaces between the balls, thus reducing the grinding action of ball on ball, and lessening the consumption of iron.

It would appear from the Inspiration experiments with the ball-mill that one-stage reduction is cheaper than multiple-stage reduction. Judging from this, the logical design for an all-sliming plant would include nothing but ball-mills working on closed circuit with classifiers, thus eliminating stamps, tube-mills, and intermediate crushers, such as Chilean mills, rolls, etc. Whether or not the ball-mill would operate as efficiently when producing a 200-mesh product, as it does when producing a 48-mesh product, is a question still open to experiment. It is quite possible that the tube-mill could be used to advantage as the final-crushing device. The question of the proper size for tube-mill feed is still undecided and probably always will be as long as the character of ores varies. The Mines Trials Committee at Johannesburg decided that from 3 to 4-mesh feed gave the best results on their ore.

In his article on the operation of the Goldfield Consolidated mill, J. W. Hutchinson says that 16-mesh feed gives the best results on that ore. In the experiments at the Inspiration, the best results were obtained on a feed that passed 8-mesh. All of the mills at Tonopah use a finer feed than 4-mesh. The reason for the difference is this: at Johannesburg an all-slime product is not absolutely necessary; at Goldfield and Tonopah it is. Therefore it seems reasonable to believe that where an all-slime product is desired, the tube-mill feed should be finer than 8-mesh, so that, disregarding for the moment any machine that promises to perform the whole operation of reducing from coarse-crusher product to slime in one operation, the problem resolves itself into reducing a maximum of 1½-in. material to at least 8-mesh at the smallest possible cost.

This can be done in one operation or by stage-reduction consisting of two or more successive reductions. The most preferable is the cheapest. The following machines will accomplish this reduction in one operation: stamps, ball-mills, Huntington mills, roller-mills, Chilean mills, and various forms of centrifugal crushers.

With the exception of the ball-mill, all of these machines have been thoroughly tested in competition with stamps for one-stage reduction and the consensus of opinion is that stamps are preferable. But Mr. Hutchinson has shown in his operation of the Goldfield Consolidated mill that even with stamps a greater economy can be obtained in the preparation of the tube-mill feed by a two-stage reduction. By using the stamps as intermediate crushers and re-grinding the product in Chilean mills he saves enough in the tube-milling operation to enable him to save on the whole operation. There are few mills that have had an opportunity to try the two methods in competition on the same ore, but it is reasonable to suppose that the theory would hold true on other classes of ore.

The deductions made by Mr. Hutchinson are as follows:

1st. Ore may be reduced to 1-mesh in the stamp-battery more economically than to 12-mesh.

2nd. For the reduction of particles to 16-mesh, where all slime is required, stamps followed by Chilean mills are more efficient than stamps alone.

3rd. Ore may be reduced to 200-mesh in the tube-mill more economically when the mill is fed with 16-mesh than with 1-mesh.

The question now arises, can this reduction be accomplished by any other set of machines than stamps and Chilean mills? In concentrating plants it has been customary for years to use rolls for this intermediate crushing. Their efficiency over any other class or kind of crusher, with the possible exception of the Symon's disc has never been questioned. As the tendency of most modern mills using stamps, with the exception of those practising amalgamation in the batteries, is to crush coarse, using the stamp merely as an intermediate crusher, therefore there is no doubt that rolls in the majority of cases would do this work at a lower cost. But rolls, unlike stamps, are not adapted to all kinds of ore. If the ore is wet or talcose, considerable difficulty is experienced in getting capacity per horse-power. When the ore is suitable for the use of rolls, the cost of reduction from 1½ to ¼ inch should not exceed half the cost of doing the same work with stamps. As to the resultant product it has been clearly proved that the amount of fine is greater in the stamp-mill product than in the product from rolls. This fact, in view of subsequent classification and further reduction, would counteract to some degree, but not entirely, the difference in cost of the two operations.

After nearly a year of testing by the Inspiration company and before the installation of the Marcy ball-mill, it appeared as if the Symons horizontal disc (called their fine disc) would be the machine adopted to perform this first stage of reduction of the product from the coarse-crushing plant. In the operation one 48-in. fine disc crusher was used; with an impact screen ahead of the disc to remove all undersize it was found that 35 to 50 tons per hour could be handled, crushing from a maximum size of 2½ in. to ¼ or about 4-mesh. The power consumed varied from 30 to 55 hp. and the total cost, including attendance, would not exceed 3 cents per ton with power at ¾ cents per kw-hour, charging the crusher with the time of one man.

One of these machines would do the entire work of the 100 stamps at the Goldfield Consolidated, taking the product of the coarse-crushing plant and reducing it to 4-mesh at a cost not to exceed 3.4c. per ton under their present conditions of power and labor. With no change in the operation from this point onward, using Chilean mills and tube-mills for re-grinding, at the same figures as furnished by Mr. Hutchinson, the total cost of this three-stage reduction would be 30.6c. or a saving of 10c. per ton over the present system of using stamps for the first stage.

Of course, it is impossible to give any general figure as to the cost of operating stamps; various conditions, cost of power, character of ore, and labor vary to such an extent. The published costs range from 9 to 60c. per ton, and it is only when comparisons are made between two systems on the same ore, as Mr. Hutchinson has done, that the relative efficiency can be determined; but I believe I am safe on the estimate for the use of the Symons disc on Goldfield Consolidated ore, which is not as difficult to crush as that of the Inspiration. No doubt equally as good results could be obtained on this ore by the use of ball-mills.

Up to the time of the first installation of the Marcy machine, the ball-mill, while in extensive use as a dry-crusher, was not considered generally as a wet-crushing mill. H. W. Hardinge has been an advocate of the use of ball-mills in place of stamps for a number of years, and in a conversation with him in Arizona in 1914 he predicted the gradual abandonment of the stamp in favor of the wet crushing ball-mill. The adoption of ball-mills by the Inspiration company after a year of testing on all classes of crushing machinery, and the recent decision by one of the large mining companies of Alaska to use ball-mills in preference to stamps would indicate that the results obtained by this machine are better than anything else on the market, both as to lowness of cost and general efficiency, considering ball-mills rather as a type and making no distinction between the different makes.

The great capacity of the Marcy ball-mill is obtained by the use of the peripheral discharge and a proper consistence of the pulp. The peripheral discharge attains a point long desired by the tube-mill, that is, a rapid discharge of particles already crushed to the desired fineness, the retention of which by the tube-mill causes a sort of mush to form from about the centre of the mill to the discharge end, furnishing a cushion for the pebbles and retarding grinding. It is also claimed that the proper consistence of the pulp effects a saving in the amount of iron consumed. A publication of the results obtained by the Inspiration company in the operation of the various machines used by them in their test-mill would be a contribution to the art well worth receiving.

Whether or not the ball-mill will replace the stamp-mill in the future, its development will be watched with much interest. One manufacturer is making a mill with a baffle back of the screen, by means of which the height of the discharge can be regulated from a straight peripheral discharge to a complete centre-discharge. The benefits claimed are a better regulation of the product, making in one operation whatever is required from 40-mesh to all-slime material.

Whether it is cheaper to make a slime product in one operation or classify and treat the oversize in a tube-mill is still a matter of experiment. With the improvement in balls, a reduction in their cost, and the better methods of using them, it is claimed by some operators that they are cheaper than pebbles. A number of experiments are now being made by several companies in the use of balls in tube-mills, cutting down the size of tube-mills by the use of screen-baffles.

The Present Value of a Mine

By F. Sommer Schmidt

The question of determining the 'present value' of an annuity yielding dividends at $R\%$ and replacing capital by a sinking fund at $t\%$ is one that arises occasionally in valuing a mining stock. When such an occasion does arise, few engineers are sufficiently conversant with this phase of mathematics to solve problems at all out of the ordinary, and then only when armed to the teeth with various tables.

Having recently been thrown against a problem of this nature that could not be solved by a simple use of tables, I was forced to originate a formula of my own. In so doing, I became interested in the question and decided that many of my colleagues would welcome such a statement of mathematical relationship as would enable them to solve these problems with the use of logarithmic tables, or compound-interest tables, or sinking-fund tables, or present-value tables, as the case might be.

In the following I use the word 'dividend' to represent the total net profit available for distribution, 'interest' to represent the annual income expected from the investment, which item is considered separate and apart from the 'sinking fund' that must replace capital. Therefore dividend = interest + sinking fund.

Let us assume that we have a table of the present value of an annuity that yields interest at $R\%$ and replaces capital by a sinking fund at $t\%$ in n years, but that the range of the table is not great enough, or that there are not sufficient decimal places. Our table is limited to 10% and 4% for 50 years, and we desire 10% and 5% for 100 years.

If we have a sinking-fund table the problem is simplified. Such tables are easily procured, reading to 10% for 100 years to 6 decimal places. Then we can figure as follows:

From our sinking-fund tables we find that we must put aside \$0.000383 each year to have \$1 at the end of the required 100 years at the required 5%. If our investment must also pay interest of 10% on the dollar each year, it is necessary to earn \$0.000383 + \$0.10 = \$0.100383 or an annuity of \$0.100383 = \$1 in 100 years under the conditions, and the value of an annuity of \$1 $= \frac{1}{0.100383} = 9.9618$, which is the P.V. (present value) of \$1 per annum yielding 10% interest and replacing itself at 5% in 100 years.

To prove this, we have 10% interest on our investment of 9.9618, or 0.99618, to be paid out of the \$1 annuity, leaving 0.00382 for the sinking fund each year. Now from the interest tables \$1 per annum for 100 years at 5% = 2610.025, which multiplied by 0.00382 gives \$9.970, which is the replacement of our capital of 9.9618.

To solve this same problem without sinking-fund tables, we note that the sinking fund is simply the reciprocal of the \$1 per annum amount under the same conditions, which can be obtained from an interest table. Instead of simply taking the factor 0.000383 from the sinking-fund table, we note that the amount of \$1 per annum at 5% for 100 years is 2610.025, the reciprocal of which is 0.000383.

To solve this same problem with only a logarithmic table, we note:

The amount of \$1 per annum $= \frac{(1+t)^n - 1}{t}$, in which t is the interest rate, n the number of years. $(1+t)^n$ is the amount of \$1 at compound interest in n years.

To apply this formula in our example, $t = 0.05$, $n = 100$. Amount of \$1 per annum $= \frac{(1+0.05)^{100} - 1}{0.05}$ = 2610, which checks against 2610.025 as found from the tables.

We are now ready to make up a formula of our own for determining the present value of an annuity to pay interest at 4% and replace capital by sinking fund at $t\%$ in n years, which can be solved by using only a log table, is applicable under universal conditions, and is simpler than any other I know.

If $\frac{(1+t)^n - 1}{t}$ is the amount of \$1 per annum and we multiply this by the annual amount available for sinking-fund purposes, after interest has been subtracted from dividends, the product will be the total accumulation of the sinking fund, and this is what we consider the replacement of our capital and can therefore be placed in equality with the present value. Now to express this factor of 'sinking fund available' in terms of one unknown quantity we note that it is $D - R \times P$, in which D is the dividend that furnishes the interest and sinking fund, R is the rate of interest expected from the investment, and P is the present value or total accumulation of the sinking fund.

Hence $P = (D - R \times P)\left(\frac{(1+t)^n - 1}{t}\right)$, in which P is the only unknown quantity.

As an example: find the present value of an annual dividend of \$1 to yield interest on the investment at 8% and replaeing capital at 4% in 80 years.

$D = 1$. $R = 0.08$. $t = 0.04$. $n = 80$.

$$P = (1 - 0.08P)\left(\frac{(1+0.04)^{80} - 1}{0.04}\right)$$

$= (1 - 0.08P)\ 551.24$ $\therefore$ $45.099P = 551.240$.

$P = 12.2228$, which checks against 12.2228 in Inwood's tables.

As this is the factor for a dividend of \$1, it would be

multiplied by the actual number of dollars in estimated dividends.

We can now attack the problem of finding the present value of a stock that will earn a certain amount per annum for a certain number of years and then increase or decrease its earnings for the remainder of the life. There are no tables covering these conditions, and I offer the following formula as my solution:

Let P = present value
D = dividends per share 1st period
D' = dividends per share 2nd period
R = rate of interest expected
t = rate of interest of sinking fund
Y = number of years of 1st period
Y' = number of years of 2nd period

$P = (D - R \times P)$ (amount \$1 per year for Y years @ $t\%$) $\times$ (amount \$1 in Y' years @ $t\%$) $+ (D' - R \times P) \times$ (amount \$1 per year in Y' years @ $t\%$).

In this formula $D - R \times P$ = amount available for sinking fund each year in the first period. This multiplied by amount of \$1 per year in Y years @ $t\%$ is the accumulated sinking fund to end of the first period, but as this amount will stand at compound interest @ $t\%$ in the sinking fund for the whole of the second period, we multiply this by the amount of \$1 in Y' years @ $t\%$. We have now taken care of this first period and add to it the amount annually available for sinking fund during the second period multiplied by amount of \$1 per annum in Y' years @ $t\%$, which thus makes the sum total of sinking fund expressed in terms of one unknown quantity and must equal the present value.

From the same line of reasoning we would have for three stages of earnings,

$P = (D - R \times P)$ (amount \$1 per annum Y years $t\%$) $\times$ (amount \$1 in $Y' + Y''$ years $t\%$) $+ (D' - R \times P)$ (amount \$1 per annum Y' years $t\%$) $\times$ (amount \$1 in Y'' years $t\%$) $+ (D'' - R \times P)$ (amount \$1 per annum Y'' years $t\%$), in which D, D', D'' represent the dividends of three periods, and Y, Y', Y'' represent the number of years of the three periods.

As an example, take a stock that will earn \$2 per share for 20 years and then \$2.50 for 15 years. What is the present value if we expect 10% interest and a replacement of capital at 4%?

From the interest tables we note that

The amount of \$1 per annum @ 4% for 20 years	= \$29.778
The amount of \$1 per annum @ 4% for 15 years	= 20.024
The amount of \$1 @ 4% for 20 years	= 1.801

Substituting $D = 2$, $D' = 2.50$, $R = 0.10$, $t = 0.04$, $Y = 20$, $Y' = 15$,

$P = (2 - 0.10P) \times 29.778 \times 1.801 + (2.50 - 0.10P) \times 20.024$.

$P + 5.363P + 2.002P = 107.260 + 50.060$.

$P = 18.807$.

Our last equation can be put into the form:

$P\ (1 + 5.363 + 2.002) = 107.260 + 50.060$, in which the parenthesis is 1 + accumulated value @ $t\%$ of the interest @ $R\%$, and the right-hand member is the accumulated value @ $t\%$ of the dividends for total life.

We could therefore make a more concise statement of the formula as follows,

P = accumulated value @ $t\%$ of dividends for total life $-$ accumulated value @ $t\%$ of the interest @ $R\%$.

I am indebted to Charles Carpenter of the Metropolitan Life Insurance Co., for this concise form, but unfortunately the same steps and figures have to be used as given in my detailed formula.

To check our result of \$18.807 as given above we figure that 10% interest or 1.881 is to be substracted from dividends of \$2 leaving 0.119 to the sinking fund for capital redemption. This 0.119 per annum @ 4% for 20 years $= 0.119 \times 29.778 = 3.543$ accumulated in sinking fund in the first 20 years which amount now stands at interest 4% for 15 years or $3.543 \times 1.800 = 6.377$ total accumulation from dividends of the first period.

The second period interest requirements being the same, 10% of 18.807, leaves as a balance from the new dividends of 2.50 the amount of 0.619 per annum for sinking fund, which in 15 years is $0.619 \times 20.023 =$

12.394 contribution from the 2nd period
6.377 as figured for the 1st period

18.771 Total capital redeemed
18.807 Present value.

The discrepancy is simply a matter of insufficient decimal places. For simplicity, compounding of interest has been assumed to be annual.

For the benefit of those who may consult the excellent book of J. R. Finlay entitled 'Cost of Mining' (1909) on this subject, I would like to draw attention to what I consider an error, on page 16, which deals with the derivation of a 'present value' formula.

y = annual sinking fund.
D = rate + 1 at which sinking fund is invested.
X = number of years life.

The statement is then made that present value $= Y (D + D^2 + D^3 + D^4 \ldots\ldots D^x)$, with which I do not agree. We have not earned our annual sinking fund Y till the end of the first year, so that we cannot count our first year's sinking fund as YD and the second year's as YD^2, but rather that our first year's sinking fund is Y and the second year's YD, the third YD^2, etc., giving us:

Present value $= Y (1 + D + D^2 + D^3 + D^4 \ldots\ldots D^{x-1})$, which is reduced to $\frac{Y(D^x - 1)}{D - 1}$ and not $\frac{YD(D^x - 1)}{D - 1}$.

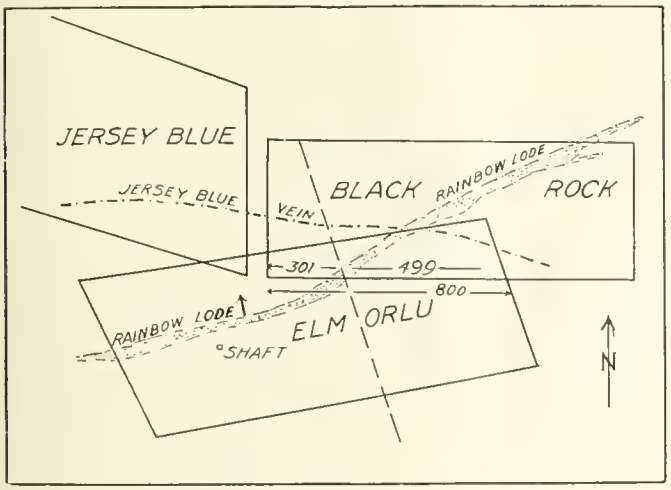
Therefore when an example is solved on page 17 involving this error, the value of S includes one superfluous factor, 1.04, giving 30.97 instead of 29.778. When substituting this former value and solving for Y the result is 0.994 instead of 1.02 as the annual sinking fund; giving the final result of 30.78 for the present value, instead of the correct one 30.39. The result obtained by Mr. Finlay does not check with the tables on his page 46.

Excellent books on this subject are: 'Inwood's Tables for the Purchasing of Estates,' revised and extended by Schooling, now in its 30th edition, published by Crosby Lockwood & Son, London; 'Cost of Mining' by J. R. Finlay; and 'Principles of Mining' by H. C. Hoover.

The Elm Orlu-Butte & Superior Decision

On page 174 of our issue of January 29 we gave a summary of the decision of Judge George M. Bourquin in the suit of the Clark-Montana Realty Co., which controls the Elm Orlu Mining Co., against the Butte & Superior Copper Co., both important zinc producers at Butte, Montana. The following are interesting abstracts from the Judge's opinion:

Plaintiff alleges that the Elm Orlu is the older location, and defendant alleges the Black Rock is. Plaintiff alleges that the apex of the Pyle strand is in the Elm Orlu and crosses the Elm Orlu east end-line, and that the vein on strike and dip unites with the Rainbow vein; and defendant denies all thereof at points east of the Rainbow apex crossing of the common side-line that would give extra-lateral rights to plaintiff. Defendant alleges that the Rainbow and Jersey Blue unite on strike and dip, and plaintiff denies it and alleges that on strike and dip the latter crosses the Rainbow. Defendant alleges the easterly strand of the Rainbow crosses



the Black Rock east end-line, and plaintiff denies it. Defendant asserts some ownership of orebodies under both claims by virtue of estoppel by deed executed by plaintiff to defendant's predecessor in interest, and plaintiff denies estoppel. Both parties allege and deny trespass and damages and accounting is desired. Appropriate legal consequences and rights are asserted by both parties. The trial consumed 16 days. There are nearly 1600 pages of testimony, and 30 exhibits. Maps and models are duplicated, save in more or less theoretical geology from which unwarranted impressions are to be avoided. The testimony is of five experts for each party, all men of eminence in geology or mining engineering or both. For plaintiff are Greene of Butte, Irving of Yale, Weed of New York, Searls of Nevada, and Winchell of Minneapolis. For defendant are Finch of Denver, Emmons of Minnesota, Salisbury of Chicago, and Burch and Wiley of California. There is some conflict of facts and more of argument, opinions, and conclusions. Most of it can be imputed to the complex geological and other problems, conditions underground, difficulties of observation, and honest differences of interpretation by reasonable and learned men. But in instances partizanship apparently impaired judgment. As a whole, however, the testimony inspires confidence and deserves careful consideration. The judge gave two days to inspection of the premises, but since some places in evidence had been stoped and others obscured by fallen ground or timbering, with intermittent crevices and small openings through which to peer and distinguish granite, altered and otherwise, slips, faults, gouges, aplite, quartz, seams, and veins, he has not been greatly aided to determine what evidence is more credible and weighty.

* * * * * * * * * * * * * * * *

A location and its record are different things. The Federal and most State statutes distinguish between them, the former even in authorizing local rules "governing the location" and "manner of recording." The statutory object is to protect and reward discoveries of mines. Discovery with intent to claim is the principal thing, and vests an estate—an immediate fixed right of present and exclusive enjoyment in the discoverer.

* * * * * * * * * * * * * * * *

If the Montana statute made recording of the nature of conditions-subsequent (of feudal origin) at common law such conditions are to be but substantially performed, and no assignee of part of the premises to which the conditions attach can take advantage of their breach; and the owners of the Black Rock securing the conflict area were at most assignees of but part of the Elm Orlu premises. The United States forfeited neither claim for defective verification—if a breach of conditions-subsequent. The estate in neither, if voidable, was avoided. Both were confirmed and patented. Where Congress intended forfeiture of mining and other public land claims for breach of conditions-subsequent it plainly said so; vide forfeiture for failure to perform or contribute to annual labor. Recording acts that expressly provide forfeiture for failure to comply with them do so in favor of only subsequent bona fide claimants. Forfeitures are odious and not to be implied. Prior to patent entry of these claims, a Montana statute provided that all ambignous statutes should be construed "in favor of natural right;" and it would not have been too far-fetched to apply it to the statute directing recordation of mining claims. In 1875 Montana was indeed primitive. Those learned in the law were few. It is doubtful if there was a lawyer in Butte. The prospectors, pioneers, and founders of this wonderful West, seeking in good faith to comply with the recordation law, for mere technical failures therein should not have been subjected to so harsh a construction of that statute and deprived, as many of them were, of their discoveries. And deprived for whom? Subsequent bona fide discoverers and locators? No; as a rule for those unspeakable creatures who search public records to discover and take advantage of defects in their neighbors' titles.

These statutes are of no more force and effect than miners' rules. Both are authorized by the one Federal statute. The better if not prevailing rule always has been that if the recordation law does not expressly provide forfeitures for failure to record, the location is valid though not recorded. Last Chance Mining Co. *v.* Bunker Hill Mining Co. 131 Fed. 585.

* * * * * * * * * * * * * * * *

For plaintiff the testimony is that the latter crossing is "about" 308—"rather the extreme and indefinite limit of the mineralization which accompanies the vein"—to 314 ft.; for defendant, "about" 300 to 301 ft. All agree there is no defined wall, that it is indefinite and leaves much to judgment. Considering the evidence in light of inspection and that the burden of proof is upon plaintiff, it is believed that the concession of defendant is more nearly right and as favorable to plaintiff as the facts warrant. The exposure is in a surface trench, and it is difficult to distinguish vein matter in place from mere seepage effect in adjacent country, whether of vein solutions or surface waters, and perhaps mushrooming beyond the limits of the vein proper below. A shaft might have contributed to accuracy. Finch testified that within the limits of the 300 he included 15 ft. to the extreme limit of rock alteration, with a few little seams in it, "to be consistent with the interpretation of a vein at other points." This is admirable frankness, but imports that at vital points and to indefinite extent he characterized that as vein which in his judgment is not vein, to serve his client and avoid hazard of comparison. The difficulty is that when an expert shades his testimony

upon the principle of *do ut des*, partizanship is likely, if not certain, to favor his client, and the court cannot determine to what extent inevitably detracting from the weight of his opinion.

* * * * * * * * * * * * * * * * *

Whether the Jersey Blue unites with the Rainbow is the most contested issue. In view of the finding that the Elm Orlu is the older location, each party contends against its own interest. During the trial and argument for the defendant, it was admitted that the Rainbow apex crosses the Elm Orlu west end line and the common side-line, that from its apex in the Elm Orlu on its dip it extends under the Black Rock, and that the great orebody in dispute west of the apex crossing at the common side-line, under both claims and in places bisected on strike by said side-line, is in said vein; and that it extends downward to the uttermost depths. These facts are conclusively proved as well. This admission overcomes the common-law presumption that defendant owns the part of that orebody under the Black Rock west of the apex crossing, and imposes upon defendant the burden of proving by a preponderance of the evidence (1) that the Black Rock is the older location, (2) that the Jersey Blue united with the Rainbow above any part of that orebody by defendant claimed. The whole is a single orebody under both claims, the apex of the whole being in the Elm Orlu. To avoid the otherwise inevitable legal consequences, the defendant must prove the union of veins even as it must prove the estoppel by deed it alleges. And this burden cannot be sustained by leaving the issue in doubt or balance. This is clear in respect to (1) that part of the orebody above the alleged union and under both claims, (2) that part of it below the union and under the Elm Orlu. And so is it in respect to that part of the same orebody below the union and under the Black Rock. Defendant confesses and avoids. In equity, as at law if a fact is admitted and another fact is averred to avoid it, the fact admitted is proved, with all its consequences, and stands as though the fact in avoidance had not been averred, unless the latter also is proved. See Clement v. Nicholson, 6 Wall. 315.

* * * * * * * * * * * * * * * * *

This mineralization outside of and between the veins is of little extent and consequence. It doubtless at some places extends from vein to vein, and some thereof in transverse fissures. But little of it is commercial value, and it by no means merges the veins. Both, as Emmons testified, retain their identity by reason of a "pretty definite limiting zone outside the two master fractures" of the two veins. It is not near as extensive as painted by defendant; otherwise, and if Finch's theory is correct (all the fissuring here is steep and seems normal—of tension), it ought to also appear where it does not, north of the veins at depth, where the north country is the hanging-wall side. The fracturing may be there, but not the mineralized "horse-tail" structure; and it is fair to infer that the mineralization between the veins came in connection with the great mineralization of the Rainbow and little from the barren Jersey Blue. These two veins have points of resemblance, but more of difference. The Jersey Blue more approximates to the "Blue" vein than to the Rainbow. Defendant's witnesses are of the opinion the Rainbow and Jersey Blue are of the same age and unite, the latter a strand of the former. Plaintiff's witnesses are of contrary opinion. The latter definitely describe places where the Jersey Blue crosses the Rainbow, from observation. But it is difficult to determine whether the testimony of defendant's witnesses unite; is theory, inference from or reflection of defendant's maps or actual underground observation. Close scrutiny of the testimony disclosed that none of defendant's witnesses testified that he actually saw in the ground a union or merger of the veins, save Finch, who was evidently put forward for the specific purpose, and in every instance, and they are but three or four, that Finch testified to a "definite junction" of the veins, or where "seen to unite," he not only did not describe the manner of the union, save in one instance that it was not along gouge, but in a "mass of ore," but he placed it in undeveloped territory or in the "horse-tail" structure and north of the Rainbow hanging wall; and he so pointed it out and measured distances on defendant's maps. Converging strike and dip are no more persuasive of union than are crossing of veins. In these premises veins are shown to cross as often if not oftener than they unite. It is a circumstance to be noted that in testimony and argument it is insisted in defendant's behalf that its maps are evidence, intended to speak for themselves, and to illustrate faults, ore, and ore structure in the veins. This may be allowed in so far as they conform to proved facts or are not self-serving. And looking to these maps, they show the Jersey Blue ore-structure at an angle to and not merging in the Rainbow structure, and abutting against faults or gouge and not against Rainbow ore. But this is largely theory. It is surprising, in view of what is involved, that so little development has been done at the points of first contact between these veins and where union or non-union or crossing ought to be more open to determination than elsewhere. It is realized development is expensive. The ground is heavy and difficult to hold. Each party did some development work for the other.

Their workings unite at many points. But in instances both parties halted development at seeming vital points, as though fearful of results damaging to their theories. To briefly review this development, it is largely post litigation. In all the years subsequent to location of the Black Rock and until this litigation threatened, no workings from the discovery shaft were on the Jersey Blue.

* * * * * * * * * * * * * * * * *

In view of all the circumstances and that reasonable and learned men may honestly differ in their interpretation of geological phenomena in these premises, the Court is constrained to say the evidence is in equipoise; and so the determination is dictated by the burden of proof. Even as defendant fails to prove the veins unite, so would plaintiff fail to prove they cross, if the burden of proof was upon it. A principle of law, however, demands that the Court shall find that the veins do cross. Defendant alleges they unite, and claims an estate by reason of it. Plaintiff denies they unite, and alleges they cross and admits a different estate in defendant by reason of it. The defendant fails to prove the union and the estate it claims, the law is it must be awarded the estate that plaintiff admits or concedes to it. And accordingly the finding is that the veins cross, and, save at the intersection, defendant is entitled to all orebodies in the Jersey Blue south of the Rainbow and wherever it goes or where plaintiff admits it goes if not otherwise found. The Rainbow strand easterly from the Black Rock discovery shaft extends about 400 ft. east and to within 250 ft. of the Black Rock east end-line, where it is cut off by a north-west fault. Even at the discovery shaft it is east of any extra-lateral rights of plaintiff. No discovery shaft was required when the Black Rock was located. Both the Jersey Blue and the Rainbow were discovered when the location was made, or at least before the patent entry. Evidently, the cropping of the two veins gave the appearance of one continuous east-west vein, and the location was made accordingly. Neither the Jersey Blue nor the Rainbow is a secondary vein. Both are primary. The Jersey Blue overlaps the Rainbow. Extra-lateral rights based on it extend east beyond where the like rights based on the Rainbow begin. Indeed, taking the course of the Jersey Blue where fixed by plaintiff south of the Rainbow, it is probable it crosses the Black Rock south side-line east of the Elm Orlu east end-line. That the Rainbow crosses both side-lines is not controlling. There can be but one set of end-lines, and if the located end lines fix extra-lateral rights upon ore-vein, as they do upon the Jersey Blue, they fix them upon all veins.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

Sharemarket Situation.—Minerals Separation Tonnage and Contracts.

The new year opened here with a notably more hopeful spirit prevailing. Renewed confidence is making its influence distinctly felt in all the markets. In the London mining market there was the usual rise of shares in anticipation of dividend disbursements at the first of the year, with a few notable advances due to special causes. Orsk shares, for example, have responded to the natural anticipation of a dividend incident to well sustained production with greatly reduced working costs. The East Rand is attracting much attention and the financing of Daggafontein has produced a good effect. One curious result has been American buying of South African shares. A number of orders for Geduld and other Rand shares have been executed for American clients and at one time 'Tanks' was in such demand as to start rumors of impending American purchase of control of either Tanganyika Concessions or Union Miniére. Actual buying in the market proved to be small and sporadic, as would have been anticipated by anyone familiar with American methods of business. Whatever negotiations, if any, were under way between principals, evidently came to nothing. Union Miniére is doing well, as are indeed all the Belgian companies in the Congo, but the shares are closely held in Brussels. The Belgians are a wealthy people, despite war losses, and are likely to hold on to what they have. After the War there will undoubtedly be re-adjustments of business relations, but bargain-hunters must not count too much upon the results of the temporary occupation of Belgium by the Germans.

Minerals Separation, despite many law-suits, is doing very well and the report presented to the shareholders by Mr. John Ballot, managing director, on December 29, showed the company to be in good condition, though the final value of its holdings will be largely conditioned on the outcome of the litigation in the United States and the length of the War. The company was incorporated ten years ago, and directly or through subsidiaries has spent £340,598 in developing, maintaining, and perfecting its patents, and in defending them in the courts. The original paid-in capital was £86,036. The remainder of the expenditure, plus investments with the cash surplus in the stock of the Australian and American companies came from royalties and represents use of the companies' patents. At the end of the year the various licensees of the company were treating about 4,500,000 tons of ore per annum by flotation and early in 1916, plants capable of treating 13,000,000 tons per annum are to be in operation. Mr. Ballot paid a high compliment to the Anaconda staff on the rapidity with which the reconstruction of the Washoe plant was carried out, and he gave his shareholders interesting details regarding the contract between Minerals Separation and Anaconda. Briefly, the Anaconda company, which acts for the Inspiration and the others, agreed to pay a minimum royalty of $300,000 between February 1, 1915, and within five days after decision by the U. S. Supreme Court of Appeals in the Hyde case. After such decision is announced, it may return its license or may continue to work under it. In case the latter be elected, it guarantees to pay royalties upon a minimum of 25,000,000 tons of ore on or before November 6, 1923. Arizona Copper is one of the three companies which comes under the terms of this contract; the fourth has not been announced. In the new Washoe plant four standard Minerals Separation machines of 600 tons per day capacity each (three active and one spare) were allotted to each of the eight units of the mill. The recovery, it was announced, has been raised from 78 to 96% since the introduction of flotation, and tailing now contains but 2 lb. copper per ton. Anaconda is building an 'all flotation' plant to treat 1200 tons per day of zinc ore.

VICTORIA, BRITISH COLUMBIA

Metal Production in 1915.—Principal Producers.—Dividends.—Metallurgical Improvements.—Safety Movement.

The total value of the mineral production of British Columbia in 1915 is estimated at $29,879,000, as follows: placer gold, $690,000; lode gold, $5,326,000; silver, $1,734,000; lead, $1,903,000; copper, $9,909,000; zinc, $1,395,000; coal, $5,432,000; coke, $1,490,000; and miscellaneous products $2,000,000. This total is $3,490,175 higher than that for 1914. In quantities of the various minerals produced there were the following changes: increases of 6250 oz. placer gold, 10,330 oz. lode gold, 97,820 oz. silver, 12,390,301 lb. copper, 4,133,533 lb. zinc, and 13,923 long tons coke; decreases of 5,319,048 lb. lead, 258,867 long tons coal, and miscellaneous products equivalent in value to $852,917.

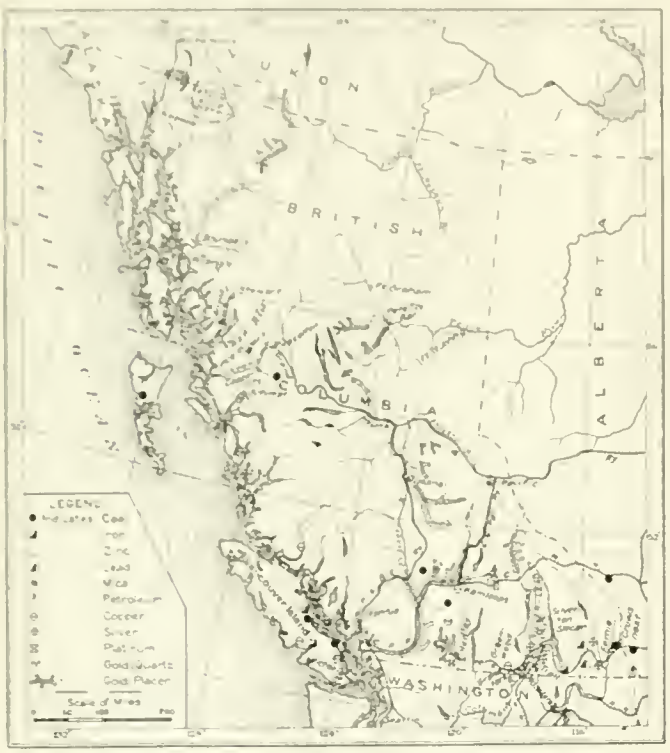
Gold was produced in largest quantity by Rossland mines, the Centre Star group and the Le Roi; other notable producers of gold were the Granby company's mines at Phoenix, and the Nickel Plate group at Hedley. Silver came mostly from Slocan mines, with the Standard far in the lead with 850,000 oz., and the Hewitt and Surprise next with from 200,000 to 300,000 oz. each. The Sullivan mine, East Kootenay, produced more than 500,000 oz. The Sullivan also made a comparatively large output of lead—about 26,000,000 lb., while of a total of 14,000,000 lb. from Slocan mines the Standard produced 8,481,000 lb. The copper output was from the Granby company's mines, nearly 22,000,000 lb. from its Hidden Creek mine, Observatory inlet, and 16,000,000 lb. from its Phoenix mines; while the Britannia added about 10,000,000 lb. to the total. Zinc was in greatest quantity from Slocan mines, the output of the Standard having been 3,789,000 lb., and that of the Surprise estimated at 2,358,000 lb. Vancouver Island mines produced 956,000 long tons of coal, and in addition slack that yielded 9300 tons of coke; Crowsnest district collieries made a net output of 495,000 tons of coal, besides the slack producing nearly 240,000 tons of coke. Miscellaneous minerals, chiefly stone, clay products, and portland cement, came in largest proportion from the Coast district.

The total amount paid in 1915 in dividends by metalliferous mining companies operating in British Columbia was $1,522,353. The amounts distributed by the several companies were as follows: Consolidated Mining & Smelting Co., $164,398; Granby Consolidated, $449,955; Hedley Gold Mining, $300,000; Le Roi No. 2, $58,000; and Standard Silver-Lead Mining Co., $250,000.

There was little change at gold-treatment mills, except that the Hedley company made additions to the machinery and plant at its 40-stamp mill at Hedley, Similkameen. These included a 24 by 36-in. Traylor jaw-crusher, a second 5 by 22-ft.

tube-mill with Montana Tonopah lining, and a Dorr classifier which working in continuous system with the tube-mill, is giving satisfactory results. four cyanide tanks, two being 34 by 16 ft. and two 34 by 18 ft., made of Pacific Coast fir, and a third Oliver continuous filter, 8 by 12 ft., of latest design. The hydro-electric generating station on Slocan river was completed at the beginning of the year. Its twin turbines have a capacity of 2100 hp., current is transmitted over a line 17,000 ft. long to the power house at the mill, where air is compressed for mine and mill uses and current is distributed to all motors operating the mill machinery.

For concentration of silver-lead-zinc ores, there were but few changes. Improvements were made at several mills in the Slocan district, and following the destruction by fire of the Ivanhoe mill at Sandon, the lessee, J. P. Keane, put in



MAP OF BRITISH COLUMBIA.

operation the long-idle mill near Roseberry, Slocan lake, and kept it working on custom zinc-lead ore. Further experiments in flotation, to make a higher saving of zinc, were undertaken at the Standard company's mill at Silverton, Slocan lake. Flotation is being successfully used at the mill of the Silverton Mines, Ltd., on ores from its Hewitt-Lorna Doone mine. A mill of the old Missouri type was constructed and equipped at the Galena Farm mine, also near Silverton, to make both silver-lead and silver-zinc products.

At Trail, facilities for treatment of lead ores were extended and brought up to date. A new lead-sampling mill was built and equipped with modern plant, ore-roasting facilities were increased, a third lead-furnace of large capacity and water-jacketed throughout was constructed, and more improvements were made in the Consolidated company's electrolytic lead-refinery, including the substitution of concrete tanks for wooden ones. Experimental production of electrolytic zinc having proved successful, the erection and equipment of works to have a capacity of 25 to 35 tons of spelter per day was commenced in the autumn, and it is expected this plant will be in operation shortly. No zinc is yet being produced commercially in the province by the French process.

Copper converters of the Great Falls type were put in at Trail, with the requisite blowing-engine and other accessories. The Cottrell system for the electrical precipitation of dust in furnace gases and smoke was used on a larger scale, two or three new Cottrell plants having been added. At Britannia Beach the Britannia Co. proceeded with the equipment of its new concentrating mill and enlarged Minerals Separation process plant for treatment of copper ore. At Anyox, Observatory Inlet, the Granby Consolidated put in a fourth copper furnace and an agglomerator, and made other changes and additions that increased the efficiency of its methods there.

Late in the year Sir Richard McBride resigned as Minister of Mines and was succeeded by Lorne A. Campbell, of Rossland, general manager for the West Kootenay Power & Light Co. and allied electric power companies, who has for years been active in connection with the supply of power to the larger mines and reduction works at West Kootenay and Boundary district, and also is president of a company mining coal in south-west Alberta.

The issue, in December, by the Geological Survey of Canada, of Chas. W. Drysdale's lengthy memoir on the 'Geology and Ore Deposits of Rossland, B. C.,' is noteworthy, it being the result of several years' investigation and inquiry by the author and other well-known geologists.

Mine safety has had increased attention, and Dudley Michell, of the provincial Department of Mines, instructor in first-aid and mine-rescue work, has had the ready co-operation of some of the larger mining companies, notably the Consolidated Mining & Smelting Co., which has organized safety committees at both its Le Roi mine and Trail smelter. It is hoped that the other interior district metal-mining companies will also take a real and practical interest in this beneficent work.

SONORA, CALIFORNIA

LATEST MINE DEVELOPMENTS FROM TUOLUMNE COUNTY.

General repairs and improvements are being made at the Shawmut mine. It is stated that a new orebody of good value has been opened.

A new transformer has been installed at the Atlas mine near Tuttletown. A new company has taken hold of this property under the management of J. Whitney, and expects to be in operation by the first of February.

Lessees at the Boyle and Knox mine at Stent are extracting some good ore, the ore being crushed at the Santa Ysabel mill. The Santa Ysabel mine, under the management of C. E. Shafer, is producing good ore, and the general outlook is encouraging.

The mining claim of the John Yost property near Soulsbyville has been leased by Chas. Saunders and Wm. Luckey; they have uncovered a two-foot vein of high value.

The new addition to the mill at the Dutch-App at Quartz, covering a space of 60 by 100 ft., is completed, and the foundation has been laid for the new tube-mills, elevators, concentrators, and other equipment. The plant will be ready for operation early in February. Activities underground are considerable. From the Dutch shaft, levels are being driven south into the orebodies of the App, and north into the Sweeney, while extensive development is being done in the Dutch. Walter Foster has been awarded a contract to do a great deal of the cross-cutting in the Dutch; the total length of the drifts and cross-cuts will amount to about 5000 ft., on three levels. W. J. Loring is in charge of this property.

The Republican mine at Jacksonville, is doing considerable overhauling at the McDougal claim. The mill has been completely renovated and is ready for crushing. Electric power will be used throughout.

Sinking at the Live Oak mine at Soulsbyville is progressing satisfactorily. Air is now conveyed from the Black Oak mine to operate the hoist, and is used generally about the mine for power. The vein maintains its good quality and width to encourage the operators, Blackburn, Stage, and Macomber, a partnership.

The Black Oak mill is kept busy reducing the usual quantity

of good ore, and the mine is reported to be in excellent condition.

Operations on the Addis, Moore, and Burns property, near Soulsbyville, will soon be commenced. C. W. Hopkins of the Black Oak mine, and Mr. Sweitzer of San Francisco are interested in the development of this property.

The California Gold Mining & Development Co., organized to acquire six unpatented quartz claims in this county and an option to purchase the Chapparel patented quartz mine for $10,000, has been permited to issue 34,000 shares to E. Bennett and P. A. Ellis in exchange for the claims, and an option to sell 10,000 shares at par, $1 per share, to net not less than 80c., the proceeds to be used in development and in meeting the payments, the 34,000 shares to be held in escrow pending the financing of the company.

The Springfield Mining & Development Co. last week started milling high-grade gravel. It is said that the gravel is of such value that the mill is running to capacity, which is several hundred tons per day. The management states that this is the deposit it has been looking for in the past two years. A. L. Horner is manager, and Joe. Cardamatori superintendent.

The shoot of ore that is being stoped in the Experimental mine at Columbia, is 105 ft. long with 550 ft. of backs, and will yield from $8 to $15 per ton. Forty feet beyond there is another shoot of the same character, though only about 40 ft. in length. Farther south, about 150 ft. from the face of the 2850 ft. adit, through which the property is worked, is the main shoot, which is 150 ft. long. This orebody, uncovered from the shaft on the surface, is rich, and it was to cut this at depth that the long adit was driven. The intervening shoots were unexpected. The adit was started in 1906, and with the exception of two seasons, has been steadily extended. The two-stamp mill has been discarded, and five modern stamps erected.

An electric pump has been installed at the Rawhide mine, and is doing good work. Water is being lowered at the rate of from 10 to 15 ft. per day, it now being below the 200-ft. level. J. Mocine is in charge.

The Hope mine near Sonora, is working its five-stamp mill on good ore. Last month No. 1 dividend was declared. New machinery has been installed, and the general outlook for the mine is promising.

TORONTO, ONTARIO

Further Nickel Investigations.—Porcupine Field.—Nipissing.

Independently of the work of the Ontario Nickel Commission, which is actively pursuing its investigations as to the feasibility of refining nickel in Canada, the Dominion Government is taking action in the same direction. Experts are now studying the question, and it is not unlikely that some steps will be taken during the present session of Parliament for the establishment of this industry. The question has entered on an entirely different phase to that presented a year ago, when the principal object in view was to prevent Germany from securing a supply of the refined metal from the United States. The main objection then brought forward to the proposition to prohibit the exportation of nickel matte was the fact that the principal market was in the United States, the domestic requirements being limited. With the growth of a heavy demand at high prices for the manufacture of war munitions, the situation is considerably altered, and even if an embargo on matte and ore is considered as too drastic a proposition, the encouragement of nickel refining by similar measures to those which have resulted in the establishment of the zinc and copper-refining industries may be anticipated, provided the report of the Government exports is of a favorable character.

The International Nickel Co. has decided to erect a nickel refinery in Canada. In this respect it is stated that the company wishes to co-operate with the Canadian government in its desire to have some of the nickel ore mined in the Sudbury district refined in the Dominion. During the last quarter of 1915 the company's earnings were 6.8% on the common stock. After paying the common and preferred dividends the quarter's surplus will be $733,122. The general balance-sheet at the end of 1915 was highly satisfactory, much better than previously. This is according to the *Boston News Bureau*.

During December the Alexo mine shipped 1283 tons of nickel ore to the Mond plant at Corniston.

The recent visit of a representative of one of the large English mining firms, largely interested in South African mines, to Porcupine, has given currency to a widespread report that this firm has made an offer of $25,000,000 to the Canadian Mining & Finance Co. for its Porcupine holdings, including 51% of the Hollinger stock, and the Acme-Millerton and Hollinger Extension properties, which was refused. Whether this statement is correct or not, there is a strong feeling among mining men that Porcupine is likely before long to attract British capital on a large scale, in view of the increasing cost of deep mining on the Rand, compared with the comparatively small outlay and large profits to be made in the Porcupine field. In the earlier days here there were many engineers from British investors, which had little practical result; but it is pointed out that conditions have radically changed, as the value of the field has been proved, and undeveloped properties can now be had at much more reasonable prices than those formerly asked.——The total production of the Dome for 1915 was $1,468,272 from 317,873 tons, or $4.56 per ton, compared with $1,058,629 from 219,609 tons, averaging $4.99 per ton in 1914. The Hardinge ball and pebble section of the mill will be in operation by March, which with an increase in the cyanide capacity is expected to increase the quantity to over 40,000 tons per month. The main shaft is now down over 600 ft.——The quarterly statement of the McIntyre for the three months ended December 31 shows 26,160 tons milled averaging $7.39 per ton, with a recovery of $184,233, or 95.42%. Operating costs were $4.16 per ton, and working profits $75,485. No. 4 shaft, now down 600 ft., will be sunk to a greater depth, and No. 5 shaft is down 700 ft. Diamond-drilling from this has cut an orebody at a vertical depth of 750 ft., which is 19 ft. wide, and valued at $18 per ton. It is expected that the unit of the mill will be ready to operate about the middle of February, making a capacity of 450 tons per day.——At the Schumacher, driving has been started at the 600-ft. level, and ore is being stoped from the upper levels. The mill is treating about 100 tons per day.——The Standard property, adjoining the Dome Lake, has been purchased by the Porcupine Premier company, capitalized at $1,000,000. No. 1 shaft will be sunk to 500 ft.——The Dome Extension is being unwatered. The vein system exposed just before the mine was closed three years ago will be thoroughly explored, diamond-drilling will be undertaken to cut the Dome veins at depth.

The new plant of the La Belle Kirkland in the Goodfish Lake area, which cost $20,000, is in operation.——A. M. Scott, J. P. Bickell, and associates, have purchased a claim at Boston creek, where a discovery was made showing rich sulphide ore.

Developments that promise to be important have been made at the Nipissing at Cobalt. A winze sunk on vein 490, below the fourth level of the Meyer vein system, when about 30 ft. down cut a shoot 8 in. wide assaying 7000 oz. per ton. It dipped ont of the winze in a short distance. Geological investigations indicate that a fault has lowered the formation about 100 ft., and the winze will be continued down, with the expectation that the vein can be cross-cut at depth.

Ore and concentrate shipments from Cobalt last year totaled 16,156 tons, against 18,221, 20,916, 21,632, 24,922, and 33,977 tons in the previous years respectively. This shows that the district is increasingly becoming more dependent on its own mills than sending the ore and products away for treatment.

Diamond-drilling is shortly to be started by the La Rose company at Cobalt, on ground adjoining the Chambers-Ferland.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

Mohave County

The Times Mining Co. has increased its capital from 1,000,000 to 1,500,000 $1 shares. A 25-hp. gasoline hoist, 80-hp. gasoline engine and 500-cu. ft. compressor, and drill-sharpener are being installed. Cross-cutting is under way at 150 ft. depth.——The Oatman Big Lode shaft is down 40 ft. A 25-hp. hoist has been ordered. The Times mine will supply air for machine-drills.

At the Big Jim samples taken every five feet across the 46-ft. lode at 400 ft. average $7.44 per ton. Six feet near the foot-wall assays $15.

Shafts at the Ivanhoe, Merry Widow, Fessendon, Lazy Boy, Gilt Edge, and Carter mines are down 40, 100, 200, 60, 55, and 250 ft. deep respectively.

At the 300 ft. in the Tom Reed mine a three-foot shoot is reported to assay up to $1750 per ton.

ARKANSAS

Final figures of the output of the north Arkansas field show that it was 1,226,314 lb. blende, 6,841,325 lb. lump silicate, 7,222,990 lb. milled silicate, and 138,375 lb. lead, valued at a total of $1,082,790. This is equal to about one week's production of the Missouri-Kansas-Oklahoma region.

Drew County

Since commencing work six months ago, the Yellow Rose mine at Rush has produced 450 tons of zinc ore worth $30,000, by pick and shovel work. A large pile of 15% ore is ready for the new mill, soon to be ready. From the dump worth $30,000 a profit of $15,000 is expected, $11,000 for the plant, and $4000 for treatment.

CALIFORNIA

Oil production in December amounted to 7,397,478 bbl., a small decrease. There were 2 rigs completed, 172 wells drilling, 24 completed, 4 abandoned, and 6196 producing. Stocks are down to 55,977,180 barrels. This large reserve is of considerable importance at present, as the violent storms of January 16 and 27 blew down several hundred derricks in the Bakersfield and Coalinga fields, besides doing an immense amount of other damage.

Amador County

The Retta mine near Plymouth is now called the Amador Star, according to the superintendent, R. Clark. The shaft is to be sunk at once. Electric motors are being installed.

Butte County

An old prospector named A. Garand found a nugget worth $1200 at the Red Hill mine near Magalia last week. The old Willard claim there yielded a 54-lb. nugget many years ago.

Calaveras County

Calaveras Copper shareholders met on January 31 to approve of a plan for re-financing, designed to preserve without assessment the equity in the property. This is with a view to showing if earnings may ultimately be developed on the 375,750 outstanding shares. It was proposed to extend at 6% interest debts totaling about $750,000, provided the company agrees to pay no dividends until all indebtedness is liquidated. Holders of the bonds and of such debentures as may be issued in the extension will be given the right to vote.

The Gravel Deposits Mining Co. of San Francisco is operating a property in the Mokelumne Hill district called the Veith Pelletion placer mine. An old adit is being re-opened, and some machinery will be installed in the spring.

Eldorado County

In a cross-cut driven from near the face of the old main cross-cut in the Pre-volcanic gravel mine, 18 miles east of Placerville, at about 1350 ft. in from the portal of the adit and 100 ft. vertical depth from the surface, gravel on bedrock is yielding $1 to $3 per pan. J. H. Zimmerman had leased the mine to a Mr. Alexander of Los Angeles. Owing to snow work has been suspended.

Plumas County

Good progress is reported from the Walker mine near Portola in mill construction, and before long the 100-ton plant will be at work.

Shasta County

Along the river on the east side of Redding the El Oro Dredging Co. of Oroville is prospecting with a Keystone drill. The company has an option on 400 acres.

TYPICAL CALIFORNIAN OILFIELD.

Trinity County

In our issue of last week it was stated that the Alta Bert company's property had been sold; this is not so.

When the Crown Reserve company of Cobalt, Ontario, acquired the Globe Consolidated property near Dedrick, the Globe Consolidated Lease Incorporated was organized to oper-

ate it. The mill is treating 125 tons of $9 ore per day. Deeper exploration is showing a good deal of ore.

COLORADO

Chaffee County

At Salida, a plant to treat complex zinc ore from the North Fork Power & Mines Co.'s property is being installed in the Stiver's factory building on Front street, by J. W. Emerson, and will be under the supervision of S. V. V. Zabriskie, formerly with the New Jersey Zinc Co. Ores from other mines will be treated later. A new patented process, claimed to be better than flotation, is to be used.

Gilpin County

Lessees and tributers in Gilpin county are said to be complaining abont the unreasonable rates of the Chamberlain Sampling Co. at Black Hawk; sampling, freight, and treatment are considered to be much too high.

The Pittsburg mine in Rnssell gulch continues to produce rich ore; recent shipments settled for up to 9.43 oz. gold, 11.5 oz. silver, and 18% copper.

La Plata County

Snow-slides practically buried the town of La Plata on January 29.

Ouray County

The Mt. Hayden Mining & Milling Co. has been organized to operate the Thistledown Mining & Milling Co.'s property at Mt. Hayden, sold last spring at a sheriff's sale.

The new experimental flotation plant of C. R. Wilfley is in operation at Ouray. It includes crushers, vibrating screens of different mesh, a No. 5 Wilfley table, Minerals Separation flotation machine, and accessories.

San Juan County

Prospectors along Cement creek last week found a bonlder 10-ft. diameter that had been carried down by a snow-slide and had split, showing a wide black streak which proved to be very high-grade tungsten ore. A rush to locate the source of this ore has set in, in spite of danger.

Summit County

The Tonopah Placers Co., operating three dredges near Breckenridge, reports net earnings of $90,961 in the quarter ended November 30.

A 50-ton Dorr continuous system cyanide plant is to be erected at the Jessie mine at Gold Run in conjunction with the 40-stamp mill. The partly oxidized gold ores will be tested. The mine also produces some lead and zinc ores.

Teller County (Cripple Creek)

At the Johnson-Mack lease of the Ella W. claim on Tenderfoot hill, a large body of rich ore has been opened in an adit. The daily output is a carload of good ore. This area is considerably active just now, in spite of cold weather.

IDAHO

Shoshone County (Coeur d'Alene)

(Special Correspondence.)—Regular shipments from the property of the Coeur d'Alene Antimony Mining Co., known locally as the Antimony mine, situated on Pine Creek, about five miles west of Kellogg, are now being made. The present output is one car of concentrate and sorted ore each five or six days, but soon this will be increased to about three carloads of antimony ore per week, containing between 40 and 50% antimony metal. The ore is about as pure a stibnite as can be found, as proved by the fact that the ore has never been penalized for any impurity by the smelters. The ore-shoot, as far as opened up, is over 430 ft. long, and from 1 to 5 ft. wide.

Pine Creek, January 25.

Last week the Star Antimony Co. shipped its first carload, 30 tons, of 50% antimony ore from the Brown-Finnell mine on Pine Creek. This was hand sorted and jigged.

It is reported at Wallace that the Bunker Hill & Sullivan smelter will be built at Kellogg. Also that the Chicago, Milwaukee & St. Paul railroad will be extended from Coeur d'Alene into the Wallace district. Another important bearing on the region is the suit of the Washington Water Power Co. *v.* the Montana Power Co., the plaintiff alleging that the defendant is doing business here in violation of the laws of Idaho. A large nnmber of attorneys and witnesses were called to the trial, which is adjourned for 15 days.

In the Hecla mine the second ore-shoot is now 1200 ft. in depth and 800 ft. long at 900 ft. On the 1600-ft. level it is 2000 ft. long. Ten cents per share, or $100,000, was distributed recently.

During 1915 the Success Mining Co.'s income was $1,255,802, profit, $898,936, and dividends, $555,000. The surplus on December 31 was $251,111. The mine is in fine condition. On the 1200-ft. level there is 7 ft. of 25% zinc ore.

From the Golden Chest at Murray 3737 tons of hand-jigged tnngsten (scheelite) concentrate was shipped two weeks ago. Some rich ore has been found by A. Rosander on Butte creek.

The Coeur d'Alene region has been visited by severe weather, inclnding much snow, interrupting railway service and mining operations. Snow-slides are reported from several points.

MICHIGAN

Houghton County (The Copper Country)

(Special Correspondence.)—The Winona is making a small profit at present capacity, but costs are nearly 16c. per lb., and the output is not increasing much. The ore is different to other in the district, and some additional process is necessary to save the fine copper.

Good progress is being made with the new furnace at the Calumet & Hecla's Dollar Bay plant. The absorption of the Tamarack by the C. & H. has apparently been dropped for the present.

Two heads of stamps are under constrnction at the Ahmeek's mill; by July there should be eight dropping. The ore is yielding 24 lb. metal per ton. The future for many years is good.

At the Hancock 300 men are employed. The first ore to come from No. 7 shaft of the Quincy, under the joint arrangement, went to the Quincy mill last week.

The Seneca is a mine with a promising future. Ore was opened on the Kearsarge lode in 1910. The company owes nearly $200,000 to the C. & H. The Gratiot owes the C. & H. over $400,000. It has shallow possibilities on the Kearsarge lode. These two and other properties nearby could be consolidated to advantage.

Ore from the Lake mine is averaging 30 lb. per ton. The output in 1915 was 3,000,000 lb. Work is confined to a few levels, no ore being extracted from below No. 10.

Houghton, Jannary 25.

MONTANA

Severe storms passed over this State last week, considerably hampering mining, transport, and ore-treatment operations.

Silverbow County

The Butte & Superior company's Black Rock shaft is down 2000 ft. Two new three-compartment shafts will be ready for operation by the end of the year. Part of the decision in the Elm Orlu-Butte & Superior suit appears on page 220 of this issue. On January 27 a skip containing five tons of ore fell from the 800 to the 1600-ft. level, doing considerable damage to the Black Rock shaft.

NEVADA

Esmeralda County

Final figures of the Goldfield Consolidated for December show that from the treatment of 35,610 tons of ore the profit was $53,029. Costs were $4.48 per ton. Development amounted

to 2811 ft. at $5.37 per foot. In the Red Top-Laguna, 260-ft level, 700 ft. north of the shaft, 305-S sill produced 256 tons of $113.27 ore. Lessees mined 706 tons worth $9274, 96 tons was treated locally and the balance shipped to smelter.

Mineral County

Atkins, Kroll & Co.'s tungsten property, 12 miles from Sodaville, is producing 20 tons of ore daily. This is concentrated at a plant near Luning. Over 40 men are employed.

Lincoln County

Wages have been advanced 25c. per day at the Prince Consolidated at Ploche, based on 5.5-c. lead and 55-c. silver. The daily output is 400 tons.

Nye County

Tonopah mines last week yielded a total of 8390 tons of ore worth $176,280. The Belmont shipped 116,214 oz. bullion.

The Extension is to enlarge its 40-stamp mill by adding 10 more, a tube-mill, thickener, agitator, etc., to bring the monthly total to 10,000 tons.

The report of the Monarch Pittsburg Mining Co. for 1915 shows that 1806 ft. of development was done at a cost of $9.91 per foot, on the 850-ft. level in rhyolite. A vein was cut early in January, 1916, two feet assaying $36.68 per ton. Cash on hand amounts to $1550.

At Manhattan there has been some bad weather, yet important work was commenced recently.

The White Caps shaft is being deepened 100 ft. from 210 ft. The output to this depth is 19,909 tons worth $381,054, and reserves are placed at 14,285 tons of $14 ore. J. A. Cole is superintendent.

The Union Amalgamated mill has been overhauled, but heavy snow interferes with hauling ore from the mine to the plant. The assay-office was burned on January 9.

Open-cut mining at the Big Pine has been curtailed by the weather. The ore is of better grade lately. A new type of concave has been designed for crushing the schist ore. The Union mine water shaft caught fire, and after many schemes for putting it out failed chemical extinguishers were successful.

White Pine County

Mill-men and mechanics at McGill have been given an increase of 35c. per day by the Nevada Consolidated, and 20c. for common labor. This is dependent on 20-c. copper; higher prices mean a further rise. The mines are producing 12,000 tons of ore daily, employing 3000 men in all departments.

TENNESSEE

Polk County

Following a demand for increased wages the Tennessee Copper Co.'s mines are closed. The acid-plant is still in operation. According to Utley Wedge, the president, the men made their demands on January 18, and struck the following morning.

UTAH

Juab County

Following the rise in wages at the Chief Consolidated, the other companies at Tintic followed suit with a 25c. increase. Over 1300 men will benefit.

So far the shoot at 1000 ft. in the Iron Blossom has been opened for 25 ft. in width, averaging 20% copper. Some ore is being shipped, also silicious lead-silver ore, totaling 150 tons daily.

The Lower Mammoth Mining Co.'s report for 1915 has been issued. Mine development has been encouraging, and a large quantity of low-grade zinc ore has been opened. According to the general manager, J. C. Dick, 150 tons of zinc ore will be shipped per month during 1916. The output of silver-lead, zinc, and copper ore was 377, 1621, and 1113 tons respectively, worth $54,849. A dividend of $10,000 was paid, and the balance is $5578.

Salt Lake County

The president of the Alta Consolidated Mining Co., A. O. Jacobson, has issued a statement about last year's work. Adits, raises, and cross-cuts totaled 1160 ft. A shaft was sunk 105 ft., and drifts driven below the adit level on the Brain fissure. A large quantity of low-grade ore was developed, which will net a good profit when the new railway is complete. The company is free of debt.

Bad weather has interfered with shipment and reduction of the Utah Copper Co.'s concentrate at the Garfield smelter.

The Utah-Apex company is expected to make a profit of $70,000 in January, equal to $1.50 per share per annum. The output is 35,000,000 lb. lead at 3.6c. per lb. cost.

Summit County

During the week ended January 28 the Park City district shipped 1039 tons of ore. A severe storm visited the place on that day, resulting in general curtailment for the time.

Unwatering the Ontario mine, from 1500 to 1700 ft., is under way. The shaft at this depth has been full since March 1905.

Tooele County

At an altitude of 5600 ft., 18 miles west of Mercur, and halfway between West Tintic and Grantsville, is the O. K. silver mine, where ore was opened at a depth of 60 ft. in November last. This has been followed to 125 ft., the value increasing with depth. Thirty-four tons recently settled at 488 oz. silver, 0.235 oz. gold, and 0.15% copper. More is ready for the smelter.

WASHINGTON

The Knob Hill Mining Co., operating at Republic, paid an indebtedness of about $13,000 during 1915 and closed the year with cash on hand amounting to $5746, in addition to about $2100 due for ore already shipped but not settled for by the smelter, according to reports submitted to the annual shareholders' meeting in Spokane last week. The year's shipments of ore amounted to approximately 3500 tons with a gross value of $80,000. Smelter returns amounted to $62,000. The gross value of the 1914 tonnage was about $75,000. During the year the directors followed the policy of developing new ore reserves and preparing the property to increase shipments at a future time, expending $7795 on development and $1500 on improvements.

Spokane County

So far for January, companies in the North-west in which Spokane people are interested, have paid $628,850 in dividends, or $377,100 more than in that period of last year.

Stevens County

The present rate of shipments of the United Copper mine at Chewelah is 1000 tons of crude ore and 500 tons of concentrate, averaging 4.42% copper and 16 oz. silver and 13.38% and 42 oz., respectively, per month. Profits in January are expected to be over $25,000.

WISCONSIN

Grant County

(Special Correspondence.)—At Platteville the Empire Separators, working here for six years, are being removed. The Wilson mine at Potosi, is making 60% wet concentrate, and new bodies of ore have been opened, enhancing the value of the property. Two local separating-plants restored during the summer of 1915 are working steadily on crude ore. Many drilling outfits are engaged with good results.

At Cuba the National Separating Works is handling 700 to 800 tons of raw ore per week, and shipments of refined ore are from 7 to 10 cars. Strikes with drill were made on the Dall tract, where a few years ago a big dividend payer was operating and suspended, having lost the ore. Three borings, 1000 ft. west of the old Dall mine, show massive formations of zinc ore. Exploration continues.

Platteville, January 20.

LAFAYETTE COUNTY

(Special Correspondence.)—Benton continues to lead the field in production, shipping weekly from 35 to 50 cars zinc products of all grades. The Hird is a new mine developed in 1915, and a complete new 500-ton mill and power-plant is being erected.——Serious complaints are filed by all leading operators in this section of the field against the power service being supplied by H. M. Byllesby & Co. of Chicago, station at Galena, Ill.——The New Jersey Zinc Co. has drilled the Meloy lease and a complete power and milling plant will be supplied at once.

The New Diggings district, little known early in 1915, now bids fair to become the leading producer of this region. A great deal of new work is under way, while production increases.

Benton, January 20.

WYOMING

Among the undeveloped resources of the State of Wyoming, the U. S. Geological Survey reports, are bituminous shale, volcanic ash, graphite, asphaltum, manganese ores, bentonite (a clay), tin, salt, bismuth and, perhaps most important, phosphate rock, on which the future of American agriculture may largely depend. It is estimated that more than 1,250,000 acres in Wyoming are underlain by workable phosphate deposits, a phosphate area greater than that of any other State. Its coalfields cover about 41,500 sq. miles—two-fifths of the State's area—and contained originally an estimated 670,723,000,000 tons. Of this quantity only 178,000,000 tons, or about one-fortieth of 1%, has been exhausted.

CANADA

BRITISH COLUMBIA

Gold-bullion deposits at the Vancouver assay office in 1915 were 789 more than during the previous year, with an increased value of over $700,000. Of this British Columbia contributed $13,000,000, Yukon $1,150,000, and Alberta, $2000.

Sixteen mines, including the Centre Star and Le Roi, and several in Washington, sent 8766 tons of ore to the Trail smelter last week. The Lead Queen, in the Windermere region of East Kootenai, 18 miles from Frisco, sent a car of ore to the smelter.

The Spokane, Washington, Mining Men's club is to visit Rossland early in February.

The Slocan Star Mining Co., operating at Sandon, has issued $100,000 first-mortgage bonds to improve the mine and mill and give the company a reserve. A recent sale of zinc concentrate liquidated all debts. The mine is opening satisfactorily.

MEXICO

SONORA

The great drawback to resumption of mining in this State is that of transport of ore to shipping points on the railroads. Labor is not as plentiful as desired. Burros and mules are in great demand for packing, but the revolution has used up many of these animals.

According to James Malcolmson of the Tigre Mining Co., conditions are normal again at El Tigre. On account of poverty in the Bavispe River towns there is plenty of labor available. There is plenty of pack animals.

NUEVO LEON

At the A. S. & R. smelter at Monterrey five furnaces are in blast.

The annual convention of the AMERICAN CONCRETE INSTITUTE will be held at the Auditorium hotel, Chicago, February 14 to 18. Among the membership of the Institute are included some of the foremost names in the United States of engineers and architects. A large number of papers are to be read.

PERSONAL

SEELEY W. MUDD is taking a holiday in Florida.

C. W. MERRILL and ALBERT BURCH are in New York.

CHARLES E. BACON has gone to south-eastern Alaska.

W. SPENCER HUTCHINSON, of Boston, is at the Palace hotel.

H. C. ANCHOR is at the Dome Extension mine, Porcupine.

C. S. HERZIG has been visiting the Joplin district, Missouri.

JAMES M. HYDE has joined CHARLES BUTTERS in flotation work.

H. S. LEE has moved from Haileybury, Ontario, to Leadville, Colorado.

W. B. DENNIS, of the Black Butte quicksilver mine, is in San Francisco.

J. K. TURNER was in San Francisco on his return from Oatman to Goldfield.

R. E. TREMOUREUX, of the North Star Mines, was in San Francisco this week.

EDGAR A. COLLINS has resigned as manager for the Commonwealth Mining Co., at Pearce, Arizona.

L. F. LEBRUN is engineer-in-charge of re-modeling the Jerry Johnson cyanide mill, at Cripple Creek.

HUDSON H. NICHOLSON is returning to Lincoln, Nebraska, from an inspection in Plumas county, California.

CHARLES F. RAND was elected president of the United Engineering Society at the annual meeting on January 27.

FREDERICK BRADSHAW, of the Tonopah Belmont, is at the company's Surf Inlet mine on Princess Royal island, British Columbia.

ROBT. F. WOOD, formerly chemist at the Quincy Smelting Works, Hancock, Michigan, is with the Sandusky Foundry & Machine Co., of Ohio.

J. B. TYRRELL of Toronto, Canada, is sailing for England on the *Baltic* on February 9. His address while in England will be 208 Salisbury House, London, E.C.

DAVID H. LADD, of Houghton, Michigan, lately metallurgist and manager for the Wallaroo Smelting Works of South Australia, is secretary, treasurer, and general manager for the Sandusky Foundry & Machine Co., of Ohio.

J. W. BENNIE, NORMAN CARMICHAEL, and M. H. MCLEAN, managers of the Shannon, Arizona, and Detroit copper companies, respectively, have returned to resume charge of the properties, now that the strike in the Clifton-Morenci district, Arizona, is over.

W. T. BURNS has been promoted to be superintendent of electrolytic refineries, and will have charge of the electrolytic copper refinery and the electrolytic zinc plant, which is in course of construction for the Anaconda Copper Mining Co. at Great Falls, Montana. E. E. BROWNSON, formerly chief chemist, has been promoted to be assistant superintendent of the electrolytic copper refinery.

ROBERT W. CONKLIN, New York representative of the Granby Mining & Smelting Co., St. Louis, died January 10, after an illness of ten days. Pneumonia was the cause.

The Mackay School of Mines at Reno has issued a bulletin describing the work and benefits of the State Mining Laboratory. During 1915, 1085 individuals sent in 2058 samples of ores from 172 localities, resulting in 7830 determinations, an increase of 25% over the number of persons and samples in 1914. Since 1895 a total of 6003 people have sent in 11,589 samples from 1835 localities, requiring 44,792 determinations. Instructions are given in the bulletin as to how to send specimens.

The AMERICAN ASSOCIATION OF ENGINEERS of Chicago, has issued the first number of its monthly called 'The Monad.'

THE METAL MARKET

METAL PRICES

San Francisco, February 2

	Cents per pound.
Antimony	44
Electrolytic copper	26
Pig lead	6.35—7.30
Quicksilver (per flask)	$290—300
Spelter	21
Tin	43
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, February 2.

Antimony: downward trend, 50% product, per unit	$2
Chrome: 40% and over, f.o.b. cars California, per ton	15—18
Magnesite: crude, per ton, f.o.b.	7.50—10
Magnesite: plastic, no iron and lime, calcined, per ton	50
Magnesite: refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	40—50

EASTERN METAL MARKET

(By wire from New York.)

February 3.—Copper is active and strong; lead is firm owing to export demand; zinc is quiet and easier.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

A review of silver during 1915 appears on the last page of this issue. It is estimated that there is 3,000,000 oz. of silver at New York and San Francisco. Late last year there was over twice this quantity.

London advises that the Osaka mint, Japan, is to coin 15,000,000 rubles of Russian money in 10, 15, and 50 kopek pieces for the Russian government. This will consume more than 6,000,000 ounces.

Pixley and Abell of London have issued their 'Annual Circular' on silver.

Tin is quiet at 41.25 cents.

Alaska produced 200 tons of tin oxide in 1915.

The Vulcan Detinning Co.'s earnings were about 4% last year; 1916 may be 7%.

ANTIMONY

Despite continued dullness the market is strong at 42.50 to 43c., duty paid, for Chinese and Japanese grades, prompt delivery. Futures are neglected. That Great Britain has taken steps to control antimony, in much the same manner as it regulates the tin trade, has been confirmed, though the restriction is confined to the metal which comes from China or Japan in British vessels.

Eastern Metal Market

New York, January 28.

Interest in copper, lead, and zinc is largely confined to the foreign situation. In all three, domestic buying has to a great extent subsided, but the London quotations are strong, and the demand heavy. With lead, especially, it may be said, "Watch London." Russia and France have been heavy buyers of copper. The price of electrolytic continues to advance at London, and was quoted at £122 on January 27. The railroad freight embargoes that hampered consumers have been partly raised, and some large deliveries have been made, one train for New England delivery consisting of 45 cars of copper. Until the New York quotation exceeded 19c., an active business was done in zinc for domestic delivery, but the galvanizers are not heavy buyers. Business in tin has been confined to futures, consumers having learned to protect themselves. Antimony and aluminum are unchanged.

The prices of steel products continue to advance, and some eastern Pennsylvania plate-makers, where they will take business at all, are asking 3c., mill. In the last quarter of 1915 the earnings of the United States Steel Coroporation were $51,232,788, and the total earnings of the year $130,351,296. Those in 1914 were $71,663,615, indicating a gain of about 82%. Russian interests are inquiring for great quantities of metal-working machinery in this market, one representative alone enquiring for 3265 tools. Every branch of industry is active, and prosperity should soon permeate every part of the country, if it has not already done so.

COPPER

The market continues inactive so far as domestic buyers are concerned, and interest is largely centred in conditions abroad, especially at London, where the quotation for electrolytic advanced on January 27 to £122. The trend of the English market is confusing in view of the reported action of the British government in fixing a maximum price of £100. France and Russia have been heavy buyers of the metal, one enquiry from the French government calling for 10,000 tons for delivery throughout the next eight months. Exports in January, including the 27th, total 19,600 tons. The New York quotation for electrolytic touched 25.37½c., cash, on the 24th, for delivery in the next two or three months. Spot metal, of which little seems to be available, was quoted up to 26c., cash, New York, on that day. Lake was nominal at about the same figures. There is some evidence of easiness in quotations, but in the absence of business it is difficult to tell precisely where the market stands. It is certain, however, that the producers still control, and that any considerable show of interest on the part of consumers will quickly send the market higher. The entire trade is inclined to be bullish in sentiment. There is, temporarily at least, a betterment in the railroad-freight congestion, and some of the lines have raised their embargoes. The New York, New Haven & Hartford did so last Sunday night, and the following morniug a record-breaking shipment of 45 carloads of refined copper was started from Perth Amboy to supply the needs of consumers in New England, some of whom had been in distress. Many of the rolling-mills have their copper delivered in special shapes instead of in ordinary ingot form, and the inability to ship these shapes almost halted operations in some of the mills. In several directions it is urged that the copper producers resume the publications of production statistics, such as were issued formerly by the Copper Producers' Association. The National Conduit & Cable Co., in its *Copper Gossip*, under date of January 20 says:

"Sales during the last 30 days make up an impressive total, and it is these substantial transactions which have given apparent justification to the hardening movement of prices. There is, however, danger of carrying the upward tendency forward too aggressively. There is no doubt that 1916 will witness redoubled activity at producing centres. If confusion and unsettlement are to be avoided it will be absolutely necessary to give persistent attention to maintaining a healthy equilibrium between supply and demand. Since the former custom of making monthly reports of production and stocks on hand has gone out of fashion, the trade is without this official data upon which some intelligent opinion of the situation might be based. We venture to suggest that the present time is an especially favorable psychological moment for resuming that practice."

ZINC

Until two or three days ago the market was active, both spot and first-half deliveries moving well, but since then the market has become quieter, probably because of the higher prices which developed with the better demand. On January 27 prompt spelter was obtainable at 19c., New York, and 18.75c., St. Louis, but there was little interest shown. Futures were easier also, and on that day the minimum quotations were about 18.25c. for February, 17.75c. for March, and 15.50c. for second-quarter deliveries. It is notable that the galvanizers are buying little spelter, and they are the principal consumers of prime Western. The heavy business in brass-mill grades, which sell at around 21c., has been largely shared by two large producers. According to the trade the producers of prime Western are proceeding on the theory that it is better for them to limit their sales and get high prices, rather than sell several times the quantity and get much lower prices. London interests report that the English galvanizing trade is going from "bad to worse." Exports in January, including the 27th, total 4240 tons, but yet American sellers are reported to be behind in their export shipments.

The base price of sheet-zinc was advanced on January 26 to 24c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

The market is strong at 6.10c., New York, and 6c. to 6.02½c., St. Louis. The foreign demand has been heavy, which is largely accountable for the strong market here. Up to the 21st, when the leading interest advanced its price to 6.10c. (from 5.90c.) the market had been growing easier, but there came a change at London, and the market here followed. Spot lead at London stood at £32 5s. on the 27th. London appears to dominate the lead situation. One reason for the strength abroad, and the great demand for American lead, is that the tight ocean-freight situation stands in the way of getting supplies from Spain and Australia. It is expected that large purchases on foreign account will continue to be made. Exports of this month, including the 27th, total 3355 tons.

TIN

Business has been almost entirely confined to futures, either tin afloat or for shipment from the Far East, as has been the case for some months. In fact the character of tin buying has been greatly changed. The uncertainties of war times has caused practically all consumers to provide for their future requirements as far as they can, and therefore, while the arrivals are of generous size at the present time, almost all of the metal is the property of consumers when it arrives, and there is little left for spot trading. Spot metal was quoted on January 22 at 42c., 26th at 41.87c., and 27th at 41.75c. Arrivals of the month, up to and including the 27th, totaled 4155 tons, and there was afloat 5125 tons.

Silver in 1915

*The silver market during 1915 was affected by the exceptional conditions which attach to a state of war. It is therefore remarkable that for the first 10 months, the tenor of prices should have been so even in spite of events, which, in normal circumstances, would have left considerable impression. Throughout that period, the price showed great steadiness, and violent fluctuations were practically absent. This is the more worthy of comment when it is remembered that a quotation for forward delivery has not been made since the outbreak of war, because such a quotation forms a steadying factor by affording operators an alternative method of dealing. The demand was by no means the same as in pre-war times. Trade enquiry languished, and the Indian Bazaars for a long period abstained from purchases in London owing to the high rates of insurance and other causes.

An unusual portion of the buying derived from coinage orders on account of the British and foreign mints. As these orders were launched in order to meet urgent requirements for currency, the question of price had little weight, for the profit was ample. On the other hand, sales were almost confined to the United States, Canada, and Mexico, Europe being more a buyer than a seller. The uncertainty as to things financial practically eliminated the speculative element during the period mentioned, as purchases had to be made on a cash basis in the absence of a forward quotation. Bear sales presented difficulty for the same reason. At the beginning of the year, Eastern business, both for the Indian Bazaars and China, figured fairly largely, but the buying on the part of the former was not robust, and fell off as the year advanced.

The scantiness of supplies from Mexico, owing to internal difficulties, prevented the price from easing to any great extent. Threats of submarine interference with merchant shipping, and a falling-off in sales from the United States, owing to rising insurance rates, had the effect of lifting the price to a somewhat higher level in March. Under the stress of competing coinage orders, there was a rise, but the upward movement proved too tempting to China, and selling set-in from that quarter. Throughout April the market was healthy, being supported by the Indian Bazaars and a fair amount of coinage demand. In May shipments from the United States moderated and some Indian speculators bought for a rise. This movement, however, proved short-lived and unprofitable, and prices acquired a sagging tendency; the limited extent of Continental and other demand did not provide the stimulus of competition, while China was a frequent seller. A downward course was pursued until the lowest price of the year, was reached on July 29, 46.87 cents.

A contributory cause to the weakness about this period was anxiety felt as to the course of the monsoon in India, while Mexico was able occasionally to export silver which had to be disposed of on a somewhat unwilling market. On August 9 the United States Treasury commenced to make purchases and continued to buy with some freedom, until the price rose to a higher level. The rise was assisted by the exchange with America moving unfavorably for sellers of silver from that country.

As autumn set in the French coinage demand became insistent, and an important factor in the price. Almost from the beginning of the War complaints were made from all parts of France, including the capital itself, that the amount of 2-franc, 1-franc, and 5-centime coins in circulation was insufficient for commercial transactions. Toward the end of August a mint was established at Castel-Sarrasin.

The result of the purchase of between four and five million ounces for the United States Mint, before alluded to, and the frequent demand for other mints, was to raise the price by the end of September, notwithstanding that the Indian Bazaars abstained almost altogether from operating in this market, and China reduced its holding considerably on this side of the water. In October and succeeding months the almost continual pressure on account of English coinage imparted a very steady tone, while a certain scarcity of supplies became manifest, entailing a gradual advance in the price.

In the middle of November a careful investigation of the stock in London revealed that previous estimates had been placed too high. The ascertained total—only £750,000 ($3,600,000) in all—proved a great surprise to the East, and the Indian Bazaars, who had been inactive for many months, bought actively, and Chinese speculators were caught unawares. Buying for the usual coinage orders continued alongside the new competition, and the market got lively.

Within seven working days, November 20 to 27, the price jumped considerably. At these favorable rates the London stock was reduced further by sales on account of China, and the price became more effective as supplies became less. The rise was accompanied by a certain amount of speculative purchases by outside operators.

After the first week of December the market became somewhat depressed owing to China sales, and the price fell away. The English Mint bought largely during a large part of the year, and acquired nearly 28,000,000 ounces.

Apparent stocks of silver at the close of 1915 as closely as can be ascertained, together with the corresponding figures for the three preceding years are shown below:

	1915.	1914.	1913.	1912.
Shanghai	720,000	500,000	2,660,000	1,700,000
Bombay	6,900,000	5,000,000	1,320,000	12,000,000
At sea	3,125,000	1,500,000	2,000,000	5,700,000
London	6,800,000	11,000,000	15,800,000	15,000,000
Total, in oz.	17,545,000	18,000,000	21,780,000	34,400,000

Sycee (60-oz. shoe-shaped bars) at Shanghai for the four periods were as follows:

	Ounces.
1915	62,100,000
1914	68,000,000
1913	50,300,000
1912	22,500,000

Imports and exports of bar silver at London were as follows:

Imports.	Ounces.	Exports.	Ounces.
U. S. and Mexico	80,062,000	British India	36,300,000
Canada	11,681,000	France	10,200,000
Spain and colonies.	494,000	Holland and colonies	6,050,000
Australia	475,000	Russia	4,525,000
Other American states	270,000	Sweden	1,200,000
Egypt	238,000	Portugal and colonies	325,000
Other countries	129,000	Denmark	300,000
		Other countries	1,725,000
Total	93,349,000	Total	60,625,000

The future of silver is very difficult to foresee owing to unprecedented existing circumstances, and that may arise. There is no reason to think that the addition to silver coinage has been excessive, so much has gold been diverted from its ordinary functions.

*Abstract from the 'Annual Bullion Letter' of Samuel Montagu & Co., London.

EDITORIAL

T. A. RICKARD, Editor

COPPER shares are not nearly as high now as they were in 1907, but after the boom of that year came a collapse that proved disastrous to many speculators. They don't ring a bell on the Stock Exchange when the rise stops.

TONOPAH mine-owners think they ought to get 60 cents per ounce for their silver, to compensate for a price of 23 cents per pound on sheet-zinc. The War is playing strange tricks with metals and chemicals. What the miner gains in one direction, he loses in the other, like higher wages and increased cost of living.

DESTRUCTIVE use of alcohol in the War has caused a rise in the price of that chemical. To some of our readers the lethal use of alcohol will seem most appropriate; for example, to those who have written protesting against some recent remarks made by Mr. P. B. McDonald on the subject of prohibition. In this matter, as in others, use and abuse are in constant contrast. One man's food is another's poison, just as alcohol can be used to feed the burner of a Bunsen or blow the bomb of a Buelow.

FLOTATION is to be one of the principal topics of discussion at the forthcoming annual meeting of the Canadian Mining Institute, which is convened for March 1, 2, and 3. Mr. E. P. Mathewson is to read a paper on the frothing process as used at Anaconda and Mr. H. E. Wood is to describe the concentration of Canadian molybdenite ores by his method of film-suspension. Mr. H. W. DuBois is down for a paper on 'The Flotation of Bornite,' and Mr. T. A. Rickard is expected to contribute a general paper on 'The Flotation Process.' Incidentally, we note with pleasure that Mr. Arthur A. Cole has been nominated for the presidency of this Institute.

SAFETY in mines is a subject to which we are always willing to give space. In this issue we publish an interesting letter from Mr. Edwin Higgins, mining engineer to the Industrial Accident Commission, in which he bespeaks the friendly co-operation of operators and managers of mines in California. As to that, we feel assured that there will be no lack of willingness to give a helping hand, for the members of the Commission have shown notable good sense and sagacity in their treatment of the problem so far as they have proceeded. Mr. Higgins makes an excellent point in emphasizing the need of co-operation by the miners themselves. You cannot save either the life or health of miners who proceed to expose both recklessly. We commend the matter to the friendly attention of the superintendents, foremen, and shift-bosses in the mines of California.

WE note that the February bulletin of the American Institute of Mining Engineers contains two papers that are copyrighted by their authors. Neither of them are we anxious to re-publish in this periodical. The matter is bigger than that. Surely the acceptance of a paper under such conditions is a new departure? It used to be the custom of the Institute not only to permit re-publication, but to encourage it. We remember that articles have been reproduced in monthly technical magazines with the scantiest acknowledgment, and yet the distinguished editor who is now Secretary Emeritus used to raise no objection. This copyrighting of papers by contributors to the Transactions smacks too much of plain commercialism and accentuates unduly an apparent tendency of the Institute's policy. First came the advertising annex, then the publication of sundry obvious write-ups by machinery manufacturers, and now this irruption of an author's copyright on top of the copyright regularly obtained by the Institute itself for its bulletins as a whole.

PRICES for quicksilver exhibit what may be called a mercurial temperament. From $139 at the end of December the quotation has risen to $300 per flask. Part of this is, we believe, fictitious, but $275 has been paid and is being paid for quicksilver in San Francisco. The price in London is about $150, which is a discrepancy explained by differences of time and transport. In regard to the increased quotation, we believe it to be due largely to the demand for the fulminate of mercury, which is required for the manufacture of caps and detonators in shells and cartridges. Even in normal times nearly one-third, say, 5000 flasks of mercury, goes to the manufacturers of the blasting-caps used in mining and quarrying. Another use is in floating mines, to establish an electric contact when the mine leans to one side, as when struck by a vessel. Some of the material is required for electric appliances, but the use with which the miner chiefly associates quicksilver, namely, amalgamation, has decreased greatly, in consequence of the introduction of other processes and the greater economy in the use of quicksilver in such amalgamation as survives. Nowadays only 85,000 to 87,000 pounds, say, 1200 flasks, is diverted to this purpose. For silvering mirrors it is usual now to employ the nitrates of silver in preference to mercury. An intensified consumption of the bi-chloride of mercury as an antiseptic is another consequence of the War. We hope to ascer-

tion details concerning the present demand, which, as yet, has bothered the manufacturer and the mill man more than it has benefited the mining of metal.

IN our last issue we publish a review of the silver market in 1915. Last year, as regards silver, was characterized by an increased demand of the metal for coinage purposes, by reason of the withdrawal of gold coin from circulation. In England the 10 shilling note was expected to replace the half-sovereign, but in practice silver currency proved more attractive. It is estimated that $15,000,000 worth of silver was minted in London for coinage, the amount actually issued representing $37,154,665, an increase of $6,537,800. What happened in London was repeated in the capitals of the other principal belligerents, notably France and Russia. The highest price for silver in 1915 was one cent below the best quotation in 1914, while the bottom quotation was a fraction above that of 1914, but lower than the minimum in any other year since 1908. It is anticipated by authorities that the price will not decline in 1916; the demand is likely to increase, while the output of metal in Canada and the United States will remain steady. A general resumption of mining in Mexico would depress the price, but not until production from that country had grown to its former proportions. Europe will require more silver for coinage and the Orient will become a purchaser. On the whole, the outlook for the silver miner is good.

OUR London correspondent referred last week to the recent annual meeting of the Minerals Separation company and quoted some interesting statements made by the chairman, Mr. John Ballot, who said, among other things, that 4,500,000 tons of ore was being treated under the Minerals Separation patents in 1915, and that early in 1916 the total tonnage would be increased to 13,000,000. This is a modest estimate; indeed it perplexes us, for the tonnage treated at the present time by Minerals Separation licensees in the United States alone is fully double the maximum figure given by Mr. Ballot. At the end of 1915 the Anaconda was treating 12,000 tons daily and the Inspiration 8000 tons; thus these two companies alone account for 7,200,000 tons per annum. The Inspiration has increased to 10,000 tons capacity and will soon augment its flotation tonnage to 15,000; the Anaconda in a few months will be treating 14,400 tons daily; so that these two licensees of Minerals Separation will be treating fully 10,000,000 tons per annum. A big tonnage—about 7000—is being treated in the lead and zinc regions of Missouri, partly under M. S. benediction, besides which there are fairly large flotation plants distributed over Arizona, California, Colorado, New Mexico, and the Coeur d'Alene region in Idaho. The two zinc mines at Butte—the Elm Orlu and Butte & Superior—are treating 2300 tons per diem between them. The Arizona Copper is treating 700 tons, to be increased forthwith to 3000. The Humboldt treats 600 tons per day, the Miami about 4000 tons, and the Jackling group of copper companies about 20,000 tons. Indeed those outside the pale of Minerals Separation, and regarded by that company as infringing its patents, are treating fully 25,000 tons per day. Altogether we estimate that at the end of 1915 about 50,000 tons was being treated per day by flotation in the United States alone, a half of this being done by licensees of Minerals Separation. By the middle of the current year the tonnage treated will be 75,000 tons daily, equivalent to 27,000,000 tons, of which more than half will be tributary to Minerals Separation. Thus our last estimate would appear to approach that of Mr. Ballot, but it does not, because he includes operations all over the world, notably Australia, Canada, and Chile, while we confine our estimate to the United States alone.

Changing the Mining Law

Location of mining claims is the subject of a bill, introduced by Senator Smoot, whereby locators are given "the exclusive right of possession and enjoyment of all the surface included within the lines of their locations and of such veins, lodes, ledges, and deposits of mineral or minerals in place as lie within the block of ground bounded by vertical planes passing through such surface lines, and no such locator, his heirs or assigns, shall have the right under such location to follow any vein, lode, ledge, or other deposit outside of the limits of such claim."

This bill, S. 3762, has been read twice in the Senate and referred to the Committee on Public Lands. If passed, of course, it withdraws the extra-lateral right from all future locations. But it looks like a hasty bit of legislation, for it leaves the size and shape of locations the same as before, namely, 600 by 1500 feet. This is putting new wine into old bottles. Obviously, if vertical boundaries are to be the rule, the locator should be able to take as much or as little of his area on the dip as geologic conditions require. Since the present claim represents 900,000 square feet, why should not the new claim be 1,000,000 square feet, that is, 1000 feet square? Whether the locator should be able to vary the proportion while not exceeding the superficies is another interesting point. This bill of the Senator from Utah warrants the apprehension of the mining public. It seems to anticipate and prejudice the work of the commission that Congress has been asked to appoint with a view to a systematic revision of the mining law. The bill creating the commission has passed the Senate, but, we understand that it is likely to meet unfriendly treatment in the House; although it is an administration measure, and much desired by the Department of the Interior, it is by no means certain to pass. If it does not, and this bill of Senator Smoot should survive, the mining law will remain an excavated anachronism. If vertical sidelines are to supersede the extra-lateral right, then the pre-requisite of discovery should be abolished. That has not met with as much condemnation as the apex idea, but it is equally unscientific. If discovery must continue to be made from the surface, the practical result

might be to withdraw from mining that part of the vein in depth which is beyond the vertical planes of the man who has the top of it. Thus confusion will be worse confounded. The subject is much too complex for piecemeal legislation and we hope therefore that Senator Smoot's activity will be restrained pending the passage of the bill creating the commission, the members of which will be fitted to attack the whole subject in a scientific manner, and with a sincerity of purpose likely to command the confidence of the mining public.

Checking Fraud

Our compliments to the Commissioner of Corporations! In California, in Arizona, and in other States the passing of laws to check fraudulent promotion, by restrictions upon the grant of a charter to companies newly organized, is operating beneficially in protecting mining from many of the performances that injure its good name. We note that the other day Mr. H. L. Carnahan, the Commissioner of Corporations in this State, refused to pass the incorporation of a mining enterprise in which it was clear that the promoters were offering a large block of shares in a venture to which they themselves had contributed very little of their own money. The promoters of a company wanted to sell 20,000 shares at 75 cents per share; but they themselves had taken 125,000 shares in return for an investment of $13,200, and had declined to deposit their stock in escrow pending the financing of the company. The Commissioner informed them that "if the enterprise is sufficiently sound or affords such speculative inducements as to justify the sale of shares to the public, there should not be such reluctance on the part of the promoters to share the risk with the investors whom they ask to pay in cash more than one-half the total investment for less than one-seventh of the property and profits. Neither should they hesitate to give a reasonable assurance that it is not their purpose to unload their private holdings, either in competition with the company itself or to purchasers who may assume that they are securing treasury stock." This is sound doctrine. In another case, Mr. Carnahan laid it down as a rule that henceforth all reading matter issued by a stock-selling corporation must be submitted to him prior to publication. This will hinder misrepresentation of facts for the purpose of beguilement. In the case last cited, the promoters had published a display advertisement clearly misrepresenting the condition of the company and the character of its property. The Commissioner threatened to revoke the permit previously granted to the promoters unless they published a display advertisement in the same newspaper correcting the misstatements and advising the public to disregard them. This was done, the misdemeanor being attributed to "the enthusiasm of our advertising writer." In these matters the Commissioner is enforcing the provisions of the Investment Companies Act and the Blue Sky Law. So far as we know, the interference with the business of promotion has, as yet, only proved irksome to the organizers of illegitimate enterprise. In the hands of a fair-minded official the operation of the law will subserve the best interests of mining, for it should be the aim to render wrong dealings difficult and right dealings easy. Legitimate mining suffers continually by the diversion of capital from modest and reasonable ventures to impudent and impossible schemes. All business that is not mutually profitable is bad business.

Opportunities in Siberia

One of the consequences of the War has been an intensified study of geography, a subject in which our people are deficient, chiefly because the American continent hitherto has afforded more than enough scope for the exercise of intelligent curiosity. However, there is a geography that is parochial in its limitation and there is one that is equatorial and inter-polar in its amplitude. With the blockading of sundry trade-routes, and the diversion of commerce resulting therefrom, there has arisen a lively interest in regions outside our common ken, leading to intelligent inquiry into the characteristics and products of localities that until recently were not much more than names on maps or spots at which the globe-trotter sampled hotels. To those who live on this coast, particularly to the dwellers beside the Golden Gate, it is natural to look westward and to anticipate the possibility of improving the trade relations already existing with the opposite shore of Asia. To us, therefore, Vladivostok is more than a name, it is the portal to a continental area rich in resources; to a mining region made known to us during recent years by the professional travels of engineers educated in the universities of this State. We sense the possibilities of a larger business between our manufactories and the gold, copper, and zinc-lead mines of the Altai, the Bodaibo, and the Ural regions. Most opportunely, therefore, we are enabled to give our readers a graphic description of industrial opportunities in Siberia by a mining engineer requiring no introduction. Mr. Chester W. Purington is as well known at Boston as in Alaska, at Denver as in California. He writes frankly and freely on a subject concerning which his professional work in Siberia permits him to speak with assurance. We desire to second his appeal to the American manufacturer. Many of our people still retain the impression left by lurid melodramas of the 'Michael Strogoff' type, wherein Siberia is depicted as a land of perpetual snow and ice, populated chiefly by convicts, police, and wolves, where the knout rather than the alarm-clock spurs the laggard to productive activity. Mr. Purington supplies the corrective to this nightmare. He gives a picture of a genial land, rich in agricultural and mineral resources, a region of big perspective but not lacking an attractive foreground. As yet the products of Siberia are those of the soil, not of the factory; it is a country where hides are plentiful and shoes scarce, where furry animals abound but fur-coats are few. It is a country of unful-

fillment, beckoning for help across the Pacific to the enterprising among us. That the invitation should have been disregarded so long needs no roundabout explanation; our readers know that nothing but the spur of necessity, the inability to win enough dollars at home, will cause the average American to seek a foreign market or to go abroad to create one. His own country has afforded ample opportunity heretofore. But now the perturbation of War and the sundering of old lines of business has caused him to stand up and look beyond the immediate horizon. He hears voices from afar, and gives heed to them. Quite recently we have had several visitors coming to San Francisco from Petrograd to purchase mining machinery and supplies. Some of these have represented big mining companies in Siberia. The signs of new business are gratifying, but it has also been made evident how much is to be learned on both sides before such business can be expedited and rendered mutually satisfactory. One of the first blocks of stumbling is the question of credit. As in his dealings with South America, so in his business with Russia, the American manufacturer must learn to grant credits. The Russian is not accustomed to cash payments. Of course, the American can insist on his own way of doing things, and close the door, but we are assuming a real desire to transact business with a solvent customer. In this case, as in South America, the first step is the establishment of banking relations, if not branch-banks, in Russia, followed by the acquirement of some knowledge concerning affairs in that country. For a representative of the Lenskoie, for instance, to have to explain to an American manufacturer of machinery where and what his mines are is as absurd as for a Japanese to have to tell a Californian merchant what the Mitsu Bishi is. Another error is that of filling orders in accordance with the ideas of the manufacturer, not to please the foreign customer, particularly as regards the handling of shipments. For instance, an order was placed with a hardware jobber for some thousands of bolts, of assorted sizes, for shipment to Korea. The instructions specified that all goods were to be packed in cases made of 1½-inch lumber, banded with heavy strap-iron, endwise and lengthwise. The cases, in addition to having the usual mark, were to be striped with red paint, on the ends and on all four sides. When the order was sent to the shipping department, everybody had a good laugh at the 'foolishness' of the instructions. They had never shipped bolts that way before, so why should they begin now? Consequently the bolts were tied with bale-rope in bundles, not even wired; ordinary tags were attached and the shipment was started on its long journey. In the course of a month or two the hardware company received a letter from the purchasers informing it politely that in future they would place their orders elsewhere. Thus an account worth $50,000 per annum was lost. And this is what happened to the shipment: the loosely tied bundles of bolts were first chucked into the hold of a Pacific Mail steamer alongside the dock in San Francisco. They were discharged at Kobe and transshipped to Chinampho. From that point they were sent up the river in native boats, again discharged, finally reaching their destination in ox-carts. The fate of those bundles of bolts can be guessed; the entire lot was distributed along the trail of the setting sun. The object of the heavy cases and the strong bands is obvious. The red stripes were meant to enable the water-front coolies to pick out the freight readily, for the natives do not read English, much less the cryptic marks adorning shipping-cases. It is just as important for goods to arrive in good condition as it is for them to leave in that condition. We have recited this case in some detail in order to emphasize a mistake commonly made. To those who have no desire for foreign trade, it furnishes a method for ending such unnecessary extension of business, but to those on the look-out for new markets the tale bears a moral not to be disregarded. In Mexico they like green, red, and yellow paints on shipments; in Siberia they prefer other colors. Let them have what they want. Also credit. Also such sympathy and understanding as comes from better acquaintance. The manufacturers on this coast, if prepared to open trade with the Siberian mining companies, need go to no great trouble or expense to obtain the necessary preliminary information. Among the managers of mines and superintendents of smelters in Siberia are several of our own countrymen; most of these come to San Francisco periodically; it is for the manufacturer to make proper use of the opportunity to obtain hints and ideas directly applicable to the conduct of his business, if he desires any, with the Russian mining companies. In his article Mr. Purington makes a number of sensible suggestions. In a recent paper issued by the Federal Trade Commission we note the recommendation that manufacturers cooperate in taking the initial steps intended to develop trade with any particular region, as is done by the cartels in Germany and the comptoirs in France. Such cooperation will diminish the selling cost. That is why the so-called German rings have obtained so large a hold upon Oriental business. Such an organization facilitates scientific study and the assiduous cultivation of commercial relations, besides the establishment of complete banking connections, prepared to finance local enterprise and so win a strong position in the foreign community. The Japanese have done much the same thing in Korea and in China. We do not see why a number of manufacturers of mining machinery and supplies, each covering a separate branch of the business, should not co-operate to this end and be prepared either to meet the buyer from Russia or send their agents to Russia, and make all the banking arrangements likely to facilitate quick and safe dealings. Having some knowledge of Siberia ourselves, we can lay stress on the attractiveness of the opportunity offered to our people on this coast to develop business opportunities and professional openings in that enormous country, rich with a great diversity of mineral products, and affording a scenery and a climate that reminds one of the plains of Dakota, the valleys of Oregon, and the parks of Colorado.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Extra-Lateral Right

The Editor:

Sir—The article on this subject in your issue of December 18 agrees in general with opinions that I have stated when asked about the rights in specific cases, but there are a couple of questions relating to the cases

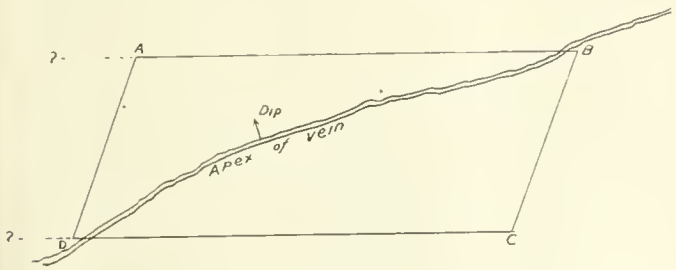

Fig. 5.

given which either you or the author may be willing to answer.

A. Where the vein cuts both side-lines, are there any limits to the application of the rule that the original side-lines become the end-lines that limit the extra-lateral

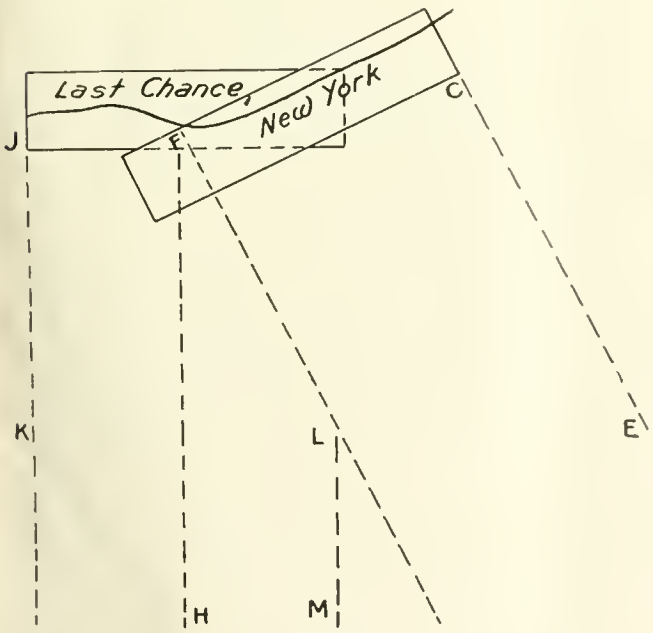

Fig 6.

rights? Suppose in Fig. 5, the vein crossed line $A\,B$ near B and the line $D\,C$ near D and dipped north, that is, parallel to the line $B\,C$; then if the rule held, the extra-lateral rights would be nearly on the strike and also the width of the claim might exceed the maximum of 600 ft. provided by the U. S. law.

B. Where there is a conflict between two claims, the rule given by Lindley in the next to the last paragraph seems reasonable. If Fig. 6 is drawn with the boundary lines extended, as per sketch herewith, in accordance with the rule given, there is a triangle $M\,L\,G$ on the vein, with its apex L far underground which has no owner. How can ownership be acquired to this piece? My idea is that, additional claims would have to be located along the outcrop of the vein adjoining the Last Chance with their end-lines parallel to the line $L\,M$; these might have no surface rights and their extra-lateral rights would not commence until the vein had passed beyond the rights of the New York claim.

E. B. Durham.

Berkeley, January 26.

A distinguished lawyer replies, on our behalf, as follows:

Replying to *Case A* propounded by your correspondent: the courts have not as yet placed any limitation on the application of the side-end line doctrine illustrated in Fig. 5 of the article contained in the issue of December 18, 1915. The enclosed diagram illustrates the hypothetical case suggested by your correspondent. The courts have not as yet been required to pass on an extreme situation of this sort. It is conceded that it would place a severe test on the side-end line doctrine; in fact, there are many who believe that the King-Amy Silversmith case announcing this doctrine was an unwarranted piece of judicial legislation, placing upon the Mining Act an interpretation which certainly was not contemplated by its framers.

It has been suggested* that "Where the vein crosses the location in such a way as to cut the side-lines at an angle of less than 45 degrees, the regular end-lines remain the end-lines."

There is no authority, however, for placing such an arbitrary limitation upon the side-end line doctrine.

Case B. While the junior claimant might exercise rights up to the plane $L\,M$, according to the so-called 'stemwinder doctrine,' there is good authority to the contrary, which would limit the extra-lateral right of the junior claim to the plane $F\,H$. However, for the purpose of answering the query of your correspondent, it is

*John M. Zane, 'A Problem in Mining Law,' 16 Harvard Law Review, page 94. See Costigan on Mining Law, page 424.

immaterial whether the extra lateral boundary plane of the junior claim be the plane *F H* or *L M*. The ownership of the underground wedge of vein *L M G* or *H F G* (whichever interpretation of the junior claim's extra lateral rights be correct), cannot be attached to any free apex, and it would be unavailing to locate additional claims on the outcrop, for the courts have never gone so far as to award an extra-lateral right to a claim that did not own at least some length of free apex. It has been suggested that locations made covering the edges of the wedge *L G M* might be considered as including a 'theoretical' apex or 'conventional' apex, but the courts have been disinclined to grant extra-lateral rights based on such constructed apices, and the suggestion has not met with favor. The courts have, however, many times held that this wedge would fall by gravity to the overlying surface owner, who would, according to well-known principles of law, own all mineral vertically beneath his surface, which is not included within a valid extra-lateral right asserted by an owner of a portion of the apex.

Prohibition in the West

The Editor:

Sir—The question of prohibition has been an extensive one, discussed for two or three generations, and it seems to me that Mr. McDonald's attempt to summarize his ideas upon it is much like teaching a system of theology at a sitting, learning French in twelve easy lessons, or telling us all about cyaniding in a column article. Probably, however, his intention rather was to draw out a wise discussion than to give a balanced idea of the merits or demerits of this important matter.

We have heard of the imperfect application of prohibition laws in some places, the better observance of them in others; but at least these laws, imperfect as they are, are better than no attempt at all, and, as experience indicates, conditions improve when such laws back up a healthy public opinion. One may always have advocates of the continuance of our most deplorable conditions. That the influence of the saloon is pernicious, in spite of its being the "poor man's club" will be conceded by any fair-minded observer when he reflects upon its ruin of manhood and the distress brought upon the innocent.

Mr. McDonald's simile regarding the eating of pancakes or red pepper is hardly convincing, since Fletcher will tell him that the first are harmless if not gobbled down, and our Mexican neighbors appreciate the second. I agree with him that there is a tendency to exaggerate various social reforms, and to set them ahead of the eternal realities, but in order to carry out reforms, the leaders must have enthusiasm, and so will exaggerate that with which they are most deeply impressed. As respects individual liberty, has not Mr. McDonald found out that in a social community, even in the United States, we are all circumscribed, and are not altogether free, that we have mutual obligations which tie us? Be not therefore discouraged; no doubt nation-wide prohibition may work effective reforms, just as it already has done in Russia.

L. S. Austin.

Salt Lake City, January 29.

The Editor:

Sir—Mr. McDonald's letter concerning prohibition has interested me considerably, although I think that to advocate moderation in the use of temperance shows an excess of caution. His experience with 'squirrel-whiskey' seems to me to have been unusually unfortunate. Personally I have always been able to get just as good whiskey in a 'dry' town as in a 'wet' one.

Generally speaking, communities have been voted dry, not because the majority of the citizens disapproved of drinking in itself, but because the saloons have thus far been either unable or unwilling to free themselves from association with 'tin-horn' gamblers and other social parasites. In addition, many voters have come to resent the domineering attitude assumed by the saloon element in the political affairs of most license communities. In fact, as a method of dealing with the liquor problem, the saloon has been a flat failure, morally and economically. It is doubtful whether there is any general solution of the problem that can be applied to all cases. Each community, or collection of communities must find for itself what is the best solution for its particular local conditions. Meanwhile, I notice that Mr. McDonald has chosen to reside in the largest dry town in California, and the only one of any size near San Francisco.

A. T. Parsons.

San Francisco, February 2.

Safety in Mining

The Editor:

Sir—Copies of 'Mine Safety Rules,' adopted by the Industrial Accident Commission of the State of California, have been mailed recently to Californian mine operators. Included with these rules were sufficient copies of 'Miscellaneous Rules for Underground Men' to supply those employed underground.

Mr. H. M. Wolffin, the former mining engineer of the Commission, spent about two years investigating the mines in this State and laying the foundation for the Mine Safety Rules through co-operation with the U. S. Bureau of Mines, the California Metal Producers' Association, mine operators, miners, and others prominent in the mining industry. On January 1, Mr. Wolffin, who had been working in co-operation with the Federal Government and the State of California, was promoted to the position of Mine Safety Engineer of the U. S. Bureau of Mines, with headquarters at Pittsburg. At that time, I was assigned to the California co-operative work under the title of Chief Mine Inspector.

As to the duties of the Chief Mine Inspector, and the method of performing those duties, I am in hearty accord with the policy established by the California Industrial Accident Commission, namely, that every effort should be made to lessen the dangers connected with all

classes of mining work, and that no pains should be spared in lending assistance to mine operators in the carrying out of the Mine Safety Rules. It is believed that an appreciable reduction in the hazards of mining in California can be brought about by equitable administration of the rules, and a continuation of the co-operation of operators and miners, which has already laid the foundation for effective safety-work.

There has been collected in the office of the inspector a vast number of data referring to safety methods and devices. This is being classified and filed, and will be augmented from many and varied sources. These data include many suggestions, with working sketches, for the cheap and efficient construction of safety-devices for all branches of work in and about the mines. It is purposed to send out, at intervals, to the operators in this State, the most interesting and valuable of these suggestions in bulletin form.

It is my belief that the equipment of mines with safety-devices is only a small part of the work of reducing the number of accidents. Co-operation of mine operators, mine officials, and above all, of the miner himself, are absolute essentials of a successful safety campaign. Assuming that this office has the co-operation of mine operators and officials and that the mines are properly equipped with safety-devices, little can be accomplished unless the miners themselves will put their shoulders to the safety-wheel and aid in turning it. It is the belief of those engaged in safety-work in mines that the co-operation of the miner is the all-important factor. A mine without safety-devices, but worked by men who are careful and who are constantly on the look-out to avoid mishaps will have far less accidents than the mine fully equipped with safety-devices but worked by careless miners.

This is intended as an appeal to the miner to lend his assistance in the work of lessening the hazards of mining in the State of California. Possibly it has never occurred to him that the establishment of the Mining Division by the Industrial Accident Commission was brought about solely to protect him; that the expense of operating this division is incurred by the State for his benefit; and that the money which operators must spend in complying with the Mine Safety Rules will bring about better conditions for him. In view of the activities of the State and Federal governments, mine operators, and others to protect the life and limb of the miner, it is believed that the miner will respond to this effort with an equal amount of interest.

The miner might ask: "What can I do to increase safety in the mines?" There are a great many things that the miner can do to help in this work.

He can be on his guard to prevent injury to himself and to his fellow workman.

He can use his knowledge and experience in preventing a greenhorn from doing something that will result in an accident.

He can lend a helping hand to his fellow workman who has a job that is too heavy for one man.

He can familiarize himself with his working-place, and with the conditions in and about the mine in which he works, so that he can intelligently avoid accidents.

Remembering that the greatest number of accidents are caused by falls of rock and ore, by falling down or into unprotected open places, and through haulage and tramming, he can be continually on his guard against such accidents.

By doing these things the miner will not only benefit himself and those dependent upon him, but he will perform what is due of every man toward his fellow.

EDWIN HIGGINS.

San Francisco, February 2.

Libraries in Mining Towns

The Editor:

Sir—This is an appeal on behalf of the traveling engineer to his more fortunate brother whose home is somewhere besides the particular place where he happens to hang his hat.

Those of us who travel can carry few technical books with us. Frequently we wish to look up some point, and naturally have recourse to the public library of the city in which we happen to be staying. I have been much surprised to find that very few, in fact practically none of the libraries in the mining towns have any books, to speak of, of technical interest to a mining engineer. The same is true of mining magazines.

Recently I went into a library which had an unusually large number of books on its shelves and a building that would have been a credit to a town three times its size, and asked for Lindgren's 'Tertiary Gravels.' I knew from the way the librarian answered me that she had never heard of the book, and when I explained what it was, she referred me to their books on geology and mining, not over 10 volumes all told. And this was in the largest gold-producing county in California and the town that has probably shipped more placer gold than any other in the world.

The visitor usually seeks local information, the kind that is embodied in the reports of the Geological Survey and State Mining Bureaus. Most of these can be obtained without cost or at a nominal figure. I have no doubt that the libraries would be glad to put these books on their shelves if the matter were brought to their attention. Cannot some of the engineers living in the different mining centres take this up with the librarians and assist them in preparing a list of the geological reports and water-supply papers of local importance?

LEROY A. PALMER.

San Francisco, January 24.

[We second this appeal, having had almost exactly similar experience in the public libraries of mining towns that should know better. On occasion we have not been able to obtain even copies of the better mining or technical weeklies, although the reading-tables would be littered with lugubrious magazines on social topics.—EDITOR.]

A Glossary of Flotation

PULP is powdered ore mixed with water.

FILM. A coating or layer, a thin membrane.

ABSORB. To drink in, suck up, like a sponge.

MODIFY. To change in character or properties.

CONTAMINATE. To make impure by contact or admixture.

SKIN. An outside layer, coat, or covering. From A. S. *scinn*, ice.

NASCENT. Coming into being, beginning to develop. From L. *nascens*, being born.

OCCLUDE. To shut or close pores or other openings. From L. *ob*, before, *claudo*, close.

PINE-OIL is a derivative of wood-tar, as phenol and cresol are derivatives of coal-tar.

LEVITATION. The act of rendering light or buoyant. L. *levitas*, lightness, from *levis*, light.

FROTH. A collection of bubbles resulting from fermentation, effervescence, or agitation.

GANGUE. The non-metalliferous or non-valuable metalliferous minerals in the ore; veinstone.

GREASE. Animal fat when soft. Also anything oily or unctuous. From the French *graisse*.

SURFACE TENSION is the contractile force at the surface of a liquid whereby resistance is offered to rupture.

GRANULATION is the state or process of being formed into grains or small particles. From L. *granum*, a grain.

FLOTATION is the act or state of floating, from the French *flottaison*, water-line, and *flotter*, to float, to waft.

ADSORB. To condense and hold a gas on the surface of a solid, particularly metals. From L. *ad*, to, and *sorbeo*, suck in.

VESICLE. A small bladder-like cavity or hollow sphere of liquid. From L. *vesicula*, diminutive from *vesica*, bladder.

COAGULATION. The state of a liquid resulting from clotting or curdling, the act of changing to a curd-like condition.

OILY and GREASY are substantially equivalent terms. All oils are greasy. Greasiness suggests more viscidity than oiliness.

BAFFLE. That which defeats or frustrates, hence the projections or wings that divert or interrupt the flow of pulp in a vessel.

BUBBLE. A globule of air or other gas rising in a liquid; also a vesicle of water or other liquid inflated with air or other gas.

AGITATION is the act or state of being shaken, stirred, or moved with violence. From L. *agitatus*, *agito*, the frequent of *ago*, to drive.

SAPONIFICATION. Conversion into soap; the process in which fatty substances form soap, by combination with an alkali. From L. *sapo* (*n*-), soap.

OIL includes (1) fatty oils and acids, (2) essential oils, mostly of vegetal origin, such as eucalyptus and turpentine, (3) mineral oils, such as petroleum products, including lubricating oils.

OSMOSE. The tendency to mix of two liquids or gases by passing through a membrane or porous wall separating them. From G. *osmos*, pushing.

SCUM. Impure or extraneous matter that rises or collects at the surface of liquids, as vegetation on stagnant water, or dross on a bath of molten metal.

METALLIC. Of or belonging to metals, containing metals, more particularly the valuable metals that are the object of mining. From L. *metallum*, ore.

COAL-TAR is a thick, black, viscid, and opaque liquid condensed when gas is distilled from coal. Such products consist of soluble and insoluble substances.

FLOCCULENT means resembling wool, therefore woolly. Coalescing and adhering in flocks. A cloud-like mass of precipitate in a solution. From L. *floccus*, a lock of wool.

CONCENTRATE. To draw or gather together to a common centre. To reduce to a purer state by the removal of non-essential matter. From L. *con* or *cum*, with, and *centrum*, a centre.

EMULSION. Milkification. A liquid mixture in which a fatty or resinous substance is suspended in minute globules. From L. *emulgeo*, to drain out, in turn from *e*, out, and *mulgeo*, milk.

VISCOSITY is the property of liquids that causes them to resist instantaneous change of their shape or of the arrangements of their parts; internal friction; gumminess. From L. *viscum*, birdlime.

FAT is a white or yellowish substance forming the chief part of adipose tissue. It may be solid or liquid; it is insoluble in water; when treated with an alkali, the fatty acid unites with the alkaline base to make soap.

MOLECULE. The smallest part of a substance that can exist separately and still retain its composition and characteristic properties; the smallest combination of atoms that will form a given chemical compound. From F. *molécule*, diminutive from L. *moles*, mass.

OLEIC ACID is fatty acid contained in olive oil combined with cresoline. Although called 'acid' it is an oily substance and functions as oil in flotation operations; it is contained in most mixed oils and fats, from which it is obtained by saponification with an alkali. From L. *oleum*, oil.

MINERAL. Inorganic constituent of the earth's crust. As used in flotation the terms 'mineral' or 'metallic' particles hark back to the French (*minerai*, ore) and Spanish (*metal*, ore) meanings. Both terms refer to those valuable constituents in the ore that it is the object of the process to separate from the non-valuable constituents, or gangue. Sometimes 'metallic' has reference to metallic lustre, one of the chief characteristics of metals and more particularly of those metallic sulphides that are especially amenable to flotation.

The Influence of Technical Journalism on Mining Education

By T. A. Rickard

*THE subject allotted to me is a big one; in order to treat it with any hope of success I must restrict my scope to the journalism that concerns itself with the mining of minerals other than coal and to the metallurgy of minerals other than iron. The industry of coal and iron covers a wide range of human effort, quite apart from ordinary metal mining.

Under technical journalism are included the periodical publications—usually weekly, rarely monthly—that furnish articles on current technology, accompanied by editorial comment and supplemented by news concerning the progress of the mining and metallurgical industries. In order to understand the relations of this phase of the publishing business to the work of mining it is necessary to recognize, in the first place, that it is done for gain: it is supported by the advertisements of the manufacturers engaged in supplying the needs of an industry to the scientific and ethical sides of which the journal is supposed to minister. Success in this form of business depends not upon the number of subscribers, but the number of actual readers connected directly or indirectly with the selection and purchase of the machinery and supplies offered for sale on the advertising pages. The proceedings of the technical societies do not come under the heading of journalism, because they furnish neither comment nor news concerning current events, they are bound volumes or paper-covered bulletins composed of essays on technical subjects. Those that attach advertisements to their bulletins are neither amateur nor professional; they are hybrids. Journalism is a profession, just as much as mining engineering. The two professions flourish best when each is kept true to its function.

In the United States the journalism of mining has been co-existent with the application of science to the exploitation of minerals. The Mining and Scientific Press was founded at San Francisco in 1860; the *Engineering and Mining Journal* at New York in 1866. While others have come into existence, and gone out of it, during the last half-century, these two represent such educative factors as journalism has given to the mining industry in the United States.

An educative effect was barely possible 25 years ago when the best technical journals consisted of a dozen pages of heterogeneous information, including one technical article, and editorial comment so brief as to fail in creating any mental impression. It may not be gracious to say so, but it is encouraging, at least, to realize that in this field of human activity, as in others, there has been progressive development. To this may be added the postscript that the best of existing technical papers is so far behind the ideal that there remains unlimited scope for further endeavor. When some nearer approach to that ideal has been made, then indeed technical journalism may be powerfully educative; at present it is content usually to be intensely instructive. Education is the 'drawing out' of the best faculties of the mind; instruction is the conveyance of knowledge. The French distinguish between these two words much more closely than we do. We use them almost as synonyms. The technical journal sets itself to give information to those engaged in the application of science to industry. It also furnishes news concerning actual progress in the operations of the particular industry to which it is devoted. It chronicles events of technical importance and comments upon them. All of which is usually instructive, and but rarely educative.

The foregoing characterization is true, but I hope to provoke a demurrer. In so far as journalism is scientific it is also educative. The two great commandments of Science are (1) Thou shalt observe carefully; (2) Thou shalt state accurately. In so far as technical journalism respects or inculcates, by example or by precept, the fundamental principle of science, namely, truthfulness, it cannot but be an instrument of education to the human intelligence. Indubitably the recognition of the verities of fact in nature promotes a respect for veracity of thought and deed throughout human affairs. There be those that play tricks with their arithmetic as with their conscience, but, in the main, the ways of science tend to the development of intellectual honesty. And that is a gift of transcendent value to mankind. Beyond all other men, the engineer must perform his work with intellectual honesty; without it, not only does he stultify his mind but he destroys his work. The dilettante of Science may please himself with incorrect deductions without manifest injury to himself or others, but the engineer applies his reasoning to physical facts, and any blunder in the logic entails a failure in visible achievement. Therefore engineering, whether of mines or railways, is based on devotion to the truths of Nature as ascertained and systematized by Science. Hence the technical journalism that is devoted to mining engineering must, in a measure, spread scientific principles among the mining population and thereby prove educative through the inculcation of essential truth. Of course, there are some mining papers that have so sacred a regard for truth as rarely to use it, but

*A paper read before the Pan-American Scientific Congress, Washington, D. C., December 1915.

these do not come within the purview of our present discussion. On the whole, we may conclude that the exploitation of technology by journalism must contribute to the development of such a mental attitude, toward both man and nature, as is favorable to education.

So far we have considered an effect that is unconscious. Technical journalism has not posed as an educator. The intention has been to interest those directing or taking part in mining or metallurgical operations, with a view to securing them as habitual readers. If these are won, then the journal becomes an effective medium for publicity to manufacturers having machinery or supplies for sale. This practical basis of the business of journalism must be kept in mind if the discussion of the higher function of such periodical publications is to be anything more than academic. While the basis may be earthy, that is, commercial, it leaves room for a large measure of independence in the editorial sanctum. A water-tight partition is possible between the business end, which looks to the advertiser only, and the editorial end, which looks to the reader only. So long as the editor prints matter that is interesting to those engaged in mining, he is free to print what he likes, for his immediate duty, unexpressed, is to publish matter that will catch the eye and hold the attention of that particular public, mainly professional, which uses the machinery and supplies pictured on the advertising pages. With these he himself has nothing to do. In order to be interesting, that is, to merit confidence in what is written, the editor and his staff must be as detached as possible from the buying and selling of machinery, as also of mines or shares in mines —in short, aloof from anything that may undermine the intellectual honesty and the consequent trustworthiness of the reading matter, more particularly the editorial comment. In this respect the journalism of mining is more free and independent, I believe, than the daily press. The big bias of politics is largely eliminated as a factor of error. Appeal is made to a public of more than average intelligence. Independence of attitude is facilitated by the fact that subservience to any particular interest is so quickly detected and resented by the readers as to endanger the value of the paper as a medium of publicity. This tends to give the successful technical journal a character that may fit it eventually to assume the function of education consciously. As yet, its effect in this direction is incidental.

Technical descriptions of methods and processes, together with accounts of current operations, are instructive only. Except in their respect for truth, they are not educative. That function devolves upon the editorial comment and upon the discussion—in the form of correspondence—that it may evoke. When the editor's remarks were limited to short paragraphs there was little chance for the ventilation of those more subtle questions of professional conduct, civic duty, or economic insight that lie at the base of a mining engineer's education. But as the business of mining grows, the successful mining periodical expands into more pages of reading matter and reaches a size furnishing adequate space for the reasoned consideration and discussion not only of the technology of the physical operations, but also the philosophy of mining, including the ideals of conduct obtaining among all those engaged in such operations, the relations of capital and labor, the ethics of the engineers, the duties of the directors, the vagaries of the speculative public, and the other human aspects of a worldwide industry. This, of course, is truly educative.

As yet, however, these delicate and knotty problems, and the whole subjective side of the industry, cannot be said to furnish the frequent topic of technical journalism. The reasons for such infrequency or disfavor are fairly obvious: in the first place, the average reader asks for information rather than opinions, he wants the facts and data that he can use in his daily work as a consulting engineer, manager of mines, appraiser of mines, metallurgist, superintendent of mills or smelters, assayer, surveyor, economic geologist, prospector, and so forth. Just as the man who goes to the theatre expects to be amused first of all, and may accept a moral lesson incidentally, if it does not kill his amusement, so the average reader wants useful information first, and then, if the editor has space and the reader has time, the latter may give his attention to 'the great imponderables' as discussed on the editorial page. In short, a paper must succeed in giving valuable information on the concrete affairs of the mine, mill, and smelter before it can hope successfully to discourse on the abstract matter of human relationships. Moreover, such subjects provoke antagonism, which is good proof that they touch interests that are vital, both commercially and intellectually. They are controversial because the readers of the technical press are to be found on both sides of the chief issues involved, those of the buyer as well as the seller of mines, those of the shareholder as well as the director of mining companies, those of both employer and employee, those of the engineer and of his client. It is impossible to discuss the complexities arising from such relationships without offending some, that is, if it is done frankly and fearlessly—and if done in any other way it is offensive to everybody. Yet it is done, and my own belief is that it can be done not only so as to increase the usefulness and prestige of the mining press as an organ of public opinion, but also in such a manner as to advance the financial interest of the publisher, if it be assumed, as we may do confidently, that those in control of the complex activities of mining are serious and thoughtful men. Man does not live by bread alone. The men of most consequence, the capable and the successful, recognize that the more interesting and the more important aspects of engineering are beyond the scope of the slide-rule. Such men, when the day's work is done, may not desire a dose of technology; they are more likely to find satisfaction in a discussion of the principles that give life to the dry bones of fact and of the ideas that give direction to the lives of men.

Thus we come to the conclusion that the educative function of technical journalism is, as yet, sub-conscious, if not wholly unconscious: it reflects the spread of real

education among the larger part of the population engaged in mining and its related professional or industrial activities. The tremendous growth of technical training as given in the mining schools and colleges of this country is the consequence, of course, of the extraordinary increase in the production of metals, itself the result of a demand created by the rapid development of our material civilization. The increase in the metal production of the United States during 20 years is shown by the following figures:

	1894.	1914.
Gold, in ounces	1,923,619	4,440,904

Complete statistics of attendance at the Schools of Mines are not available, largely because many new schools have been started during the last two decades, but judging from the records available to me, I conclude that instruction for mining was being given to more than twice as many young men in 1914 as was the case in 1894. Thus it is readily understood why technical journalism is finding a larger and more discriminating public, and has arrived at a point when it may begin consciously to perform its educational function.

If this function is to be performed effectively, it will be not by the printing of chronicles and comments only, but by the furnishing of criticism and ideas. Literature is a criticism of life; journalism is a criticism of daily life; technical journalism must become a thoughtful criticism of all that concerns the technical man—the man who does things, the engineer, the exploiter, and the explorer. The mere compilation of descriptive articles and the recording of detailed results will be left to the technical societies, the publication of which are now so voluminous as to insure mental dyspepsia to the man who tries to assimilate them omnivorously. Even such intermittent opportunities for the exchange of ideas as are furnished by congresses and conventions cannot perform the function of journalism because they are too sporadic and too ephemeral. An educative effect can be achieved best by iterative effort. A public meeting may be stimulating momentarily, but to exert persistent influence it is necessary to use persistent methods, to present the same idea many times in various guise, to awaken interest and to hold it until a given idea has been grasped, considered, received, or rejected in favor of others that are better.

Technical publications today suffer from being too numerous and too voluminous. Twenty-five years ago a man of active mind could read all that was written on his branch of technology and could keep in touch with the allied subjects, but today the output of the technical societies, congresses, and press is beyond the compass of any individual. We shall agree that the quantity of printed matter on technical subjects is enough, and to spare. Not much of it is educative, because so little of it is critical. What is needed henceforth is to ensure that the output of new facts, new records, and new ideas shall be accompanied, checked, and disciplined by wholesome criticism. That is the duty of journalism and in the performing of that duty journalism will render the truest service to the cause of education.

Antimony in Inyo County

Antimony claims have been patented in Wild Rose canyon, on the north side of Panamint range, Inyo county, California. The vein of ore, stibnite, is said to be 3 ft. wide, and to have been developed by open cut for 1000 ft. Estimates of ore in sight have varied from 10,000 tons of 30% to 5000 tons of 50% ore; one authority claims to see a resemblance to the well-known deposit near Wadley, San Luis Potosi, Mexico. A disadvantage to the commercial development of this Californian deposit is that the nearest railroad station is 72 miles away at Searles. However, a good wagon road is said to exist and a railroad to borax deposits nearby will reduce the haul, so that the cost of transporting the ore to railroad will be less than $10 per ton. There is an antimony smelter at Los Angeles, as well as at San Francisco. Production of antimony in the United States has been almost entirely from antimonial-lead. New uses are being found for antimony, such as a proportion of antimony sulphide in match-heads and in the smear on match-boxes. Antimony ores imported into this country are subject to a duty of a cent per pound, and antimony metal 1½ cent per pound.

THE ECONOMICS OF SHOVELING was the subject of a recent lecture by L. E. Young, professor of mining in the University of Illinois delivered before the mining students of the University of California. In the Flat River lead-mining district of Missouri, said Mr. Young, the men receive a bonus of 10 cents per ton for each ton over 20. A case is on record of one man who shoveled over 55 tons per day for a week. In the Homestake gold mine, practically every ton of ore produced is shoveled by hand. A shovel deteriorates rapidly in mining work, particularly when used on a rough surface rather than on a smooth plate. After two or three weeks of hard use a shovel will be worn so much that the efficiency of the shoveler is lowered, for instance from 24 tons to 20 tons. In money value, this may be worth 50 cents, which loss, it is evident, would nearly pay for a new shovel in one shift. Claude T. Rice pointed out several years ago that in western mining districts long-handled shovels are the rule, where a man saws off the handle to suit himself, while in the Lake Superior region the short D-handled shovel prevails. He contended that the use of the long-handled shovel permitted a man to utilize his legs in shoveling, thus distributing the work among a number of muscles. The short-handled shovel, he maintained, throws the strain almost entirely on the back, making the movements slower and more laborious. Mechanical shovelers, belt-conveyors, and electric steam-shovels are being adapted increasingly for underground use in drifts and stopes.

Molecular Forces in Flotation

Surface Compression

By Dudley H. Norris

At the meeting of the local membership of the American Institute of Mining Engineers on December 14 last the question was asked by one of the speakers: "Why does the greased needle float on the surface of a tumbler of water and the wetted needle sink?" Did one or another of the experts present rise and say that it was due to 'surface tension' and then in a few well chosen words explain just exactly what 'surface tension' is? Nothing of the sort happened. The question was not only not answered, but it was unanimously avoided. It is a fair question, however, and deserves an answer.

The fact is that 'surface tension' is a misnomer. Tension is a stretching, whereas the phenomena in question are those of compression. In 'surface tension,' a bubble of air or a drop of water is pictured to the imagination as being actually of the form that it would have *if* it were contained in a film like that of a soap-bubble or a toy-balloon. That grasped, the substance of the bubble or of the drop is ignored and we are asked to occupy our minds only with the imaginary film. The reasoning appears to be: "There might be such a film, there must be, there is. Otherwise, we are not able to explain it at all." In what follows, I shall attempt to explain the phenomena discussed in terms of molecular attraction and of heat.

If you will fill a tumbler with water or other liquid and then continue carefully to pour in more; instead of running over the side, there will be a heaping up of the liquid in the tumber and a rounding of the surface, the centre of the liquid being as much as a sixteenth or even an eighth of an inch higher than the rim of the tumbler. That is the phenomenon of your 'surface tension' pure and undefiled. The same phenomenon is seen when mercury is contained in a glass vessel, even when the vessel is only partly filled. Mercury does not wet glass and where the liquid metal meets the side of the glass vessel the mercury is convex. Where, however, the tumbler is only partly filled with water the surface of the water is concave where it meets the inside of the tumbler, and the glass is wetted.

In the Miami flotation case it was stated that surface tension is a force existing in the surface of a liquid that tends to draw the liquid into the form of a sphere, this being the most compact form that a given volume can assume and the form in which it presents the least surface. This is a lovely specimen of the logical fallacy known as *post hoc ergo propter hoc*. In short it was said in the Miami case, that because the most compact form that a given volume can assume and the form in which it presents the least surface is a sphere, therefore the volume assumes that form and does so at the behest of surface tension; but as to the why and how, nothing was said, nor can they be imagined. It reads as if there had been a mass-meeting of the molecules looking to 'preparedness.' The molecule acting as chairman states the business before the assembled molecules: "Owing to the war in Europe and a hard winter coming on, the molecules must decide on some form that will be the most compact and which will present the least possible surface to an unsympathetic world. The sphere comes highly recommended. It is moved and seconded therefore that the molecules form a sphere. So ordered."

The calculus proposition that two homogeneous spheres attract each other as if their masses were collected at their centres of gravity is as true as anything human can be. It is also true that in a single homogeneous sphere, if acted on by no outside force, the cohesive attraction of its molecules for each other will act radially toward the centre and form a sphere; and it is this radial attraction and not an imaginary film or a non-existent tension, that causes the phenomena and it is probably some similar molecular attraction that causes mineral flotation.

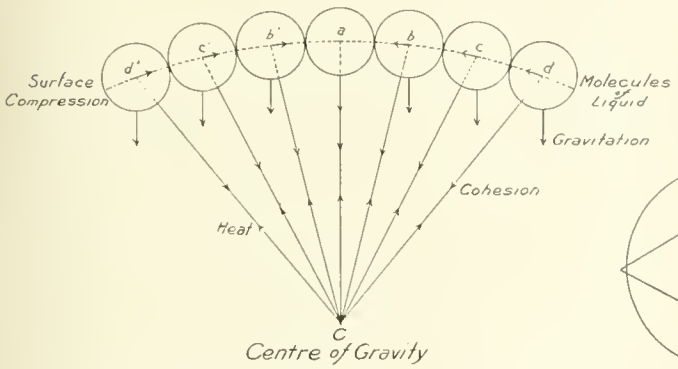
In James Clerk Maxwell's article on capillary action, in the Encyclopedia Britannica (11th edition), vol. 5, p. 258, he says: "Plateau, who made an elaborate study of the phenomena of surface tension, adopted the following method of getting rid of the effects of gravity. He formed a mixture of alcohol and water, of the same density as olive oil, and then introduced a quantity of oil into the mixture. It assumes the form of a sphere under the action of surface tension alone." That it assumes the form of a sphere is granted. That surface tension does it is denied.

The toy-balloon has a place in a rational explanation of the phenomena under discussion; but the alleged film around a drop of water or around a bubble of air, or as the top layer of a body of water, like the film of a toy-balloon, has no existence in nature. The vendor of toy balloons has each one of his gayly colored stock fastened by a string, which serves the double purpose of keeping the gas in the balloons and of keeping the balloons themselves down to earth. The free ends of the strings are brought to a common knot. There is a pull on each string along the hypothenuse of a right-angle triangle; this can be resolved into a vertical

component, tending to make the balloon float off, and a horizontal component, tending to crowd the balloons together.

The same thing happens in surface compression. The water in the tumbler is subject to the cohesive attraction of its molecules, to the attraction of gravitation, and to heat. The water, if free from the attraction of gravitation, would tend to form a sphere, but gravitation causes it to conform to the shape of the containing vessel. Heat, by tending to drive the molecules apart, acts counter to the attraction of cohesion and their equilibrium fixes the specific gravity of the water, its bulk, and its state of aggregation—making it solid, liquid, or gaseous as the case may be. If gravitation be neutralized or be not opposed, the water takes a spherical form under the influence of cohesion, as is shown in raindrops, in Plateau's experiment, and in drops of water on a hot stove, in conformity with the rule of homogeneous spheres.

Let us suppose each molecule of water in the tumbler



FORCES AFFECTING SURFACE OF WATER.

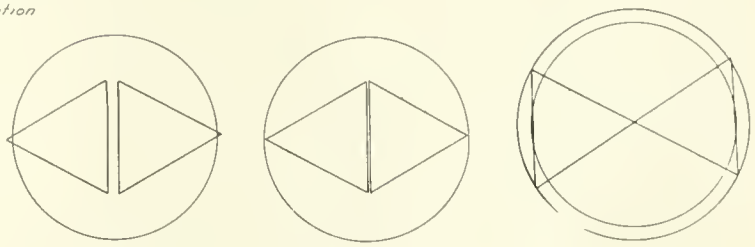
to be free from the attraction of gravitation and in the form of a sphere, then the vertical section of the surface layer would look like this:

There you have the stock of toy-balloons with the strings connecting each with a common central point. *C* is the centre of gravity of the water in the glass. The lines diverging from *C* show the directions of the forces of cohesion. The short vertical lines downward from each molecule indicate the lines of the force of gravity and the arrowheads on the cohesion lines mark the opposing forces of heat and cohesion. In the triangle, *Cad*, for example, the hypothenuse *Cd* represents the total force of cohesion; *Ca* is its vertical component, and *ad* its horizontal component. The resultant of all these horizontal components, *ad*, *ac*, *ab*, etc., is a force effecting a compression of the surface of the water. A good idea of the structure of surface compression is shown by the ripe seed-tuft of the common dandelion.

Oh, but water is not compressible. True enough, to any sensible degree by an exterior force; but the interior forces at work in water do many wonderful things. For instance, they cause water to expand on cooling and to contract on heating, between 0° C. and 4° C., and all the water phenomena of oceans, rivers, and rain-fall, of hydraulic and of steam powers, and of the irresistible force of freezing, are caused by the molecular activities existing in a drop of water.

One reason for lack of a clearer understanding of these phenomena is the failure to perceive the fact that the tendency of the water in the tumbler to form a sphere is incessant, whether the attraction of gravitation acts on the mass of the water freely, as in falling; is warded off, as in Plateau's experiment; or is superimposed upon the attraction of cohesion, compelling the water to conform to the interior shape of the tumbler and rendering the ever-present cohesion inconspicuous.

The action of water from the higher degrees of temperature, through 4° C. to ice is shown by the accompanying drawings. A molecule of water, composed of three atoms, is plausibly represented by a triangle. Two such molecules are separated a certain distance by a corresponding amount of heat and this distance fixes the volume of the mass of water, which increases and diminishes as the degree of heat is raised or lowered. At 4° the volume of water is at a minimum and it is a fair inference that the molecules of water are at that point nearer to each other than at any other point. Below 4° C. the molecular forces react in such a manner



VOLUME ABOVE 4° C. VOLUME AT 4° C. VOLUME AS ICE.

as to cause a change in the relations of the molecules themselves, causing them to turn and—in the state of ice—to assume the positions shown in the third figure, with a lower specific gravity than the water had before freezing. No other forces are necessary to the causation of the phenomena indicated than those of cohesion and heat.

Here, then, is the answer to the question asked at the meeting: By reason of the horizontal components of the attractions of cohesion which draw each molecule of water toward the centre of gravity of its mass, the surface of the water is compressed, made more dense, and offers a resistance to the needle greater than the weight of the needle. That weight is not sufficient to break apart the surface molecules but only makes a slight indentation on the surface. When the needle is wetted, capillary attraction raises the compressed surface above the needle which, no longer resting upon the denser surface, but in water not under surface compression, obeys the attraction of gravitation and sinks.

Attention was called above to the two cases of simple surface compression where the entire surface of both liquids, the water in the brim-full tumbler and the mercury in the partly filled glass vessel, are convex, whereas in the tumbler partly filled with water, the

edge of the water, where it meets the glass composing the tumbler, is concave and the water wets the glass. Thus there is added a new force which modifies the surface compression of the water and draws the water at the edge upward on the glass, forming a concavity tangent to both the surface of the water and the inside of the tumbler. It makes no difference here and now what this force is called, whether cohesion or adhesion; whether it is the same molecular attraction that exists between the molecules of the water or whether it is the cohesion of the glass acting at sensible distances, or neither, or both. The water is drawn up, not pushed up, and any drawing up is attraction, and acting on molecules it is molecular attraction.

In a tumbler 2½ inches in diameter the horizontal concavity against the glass seemed to be about $\frac{1}{16}$ of an inch wide, perhaps a little more, leaving about 2⅜ in. of convexity to ½ in. total concavity, out of the diameter of 2½ in. The vertical concavity seemed also about $\frac{1}{16}$ of an inch along the inside of the glass. With glass tubes of smaller diameter the horizontal concavity seemed to remain about the same, but the vertical concavity increased as the diameter diminished. The convexity at the centre of the surface decreased with the diameter of the circle and in a tube of ¼ in. diameter the surface of the water was an inverted hollow sphere with no convexity at all and its height above the level of the water in the tumbler was ½ of an inch. With a tube of $\frac{1}{16}$ in. diameter the water came up ¼ inch.

The surface compression at the edge of the water in the tumbler is less than nearer the centre, being practically zero, and offering no resistance to the upward attraction upon the water. If a glass tube be partly immersed in the water in the tumbler, the water in the tube, even if open at the lower end, forms a separate cohesive mass, independent of the rest of the liquid with all the phenomena of capillarity.

It has been said above that the cohesion of the water varies inversely as the temperature, being greater at the lower than at the higher temperatures, and at the boiling point there is no cohesion. With the same changes in temperature the attraction between the water and the glass sides of the tumbler varies exactly as the cohesion varies, and there is every reason to believe that the forces elevating the liquid are those of cohesion of the water and the glass acting at sensible distances. These phenomena between the water and the mercury on one hand and glass on the other are, of course, those of capillarity. They seem to fit in with the above theory of surface compression.

Then what is there left of true surface tension? Well, there is the soap-bubble. I made some experiments in this direction a few days ago with 50 or 60 soap-bubbles from 4 to 6½ inches in diameter. These were burst over a dark hardwood table about 30 inches square, so that the resulting wet spots on the surface of the table could be examined. Care was taken in every case in blowing the bubbles to remove the usual drop of water at the south pole of the bubble, so that all the wet spots came from the wreck of the distended film. After each bubble burst the table was wiped dry for the next one. When inflation ceased, one bubble 5 inches in diameter shrank an inch before it burst; another shrank from 6½ to 5 inches. In both cases the air was expelled by a real surface tension of the bubble's film. Most of the bubbles were blown until they burst, at from 1 inch to 2 feet above the table. The ones at 1 inch spread wet spots in circles from 7 to 13 inches in diameter. Of the bubbles that burst at greater distances from the table, at 6 inches above the table the wet spots extended to the edge of a circle 15 inches in diameter; at 12 inches above, 20 inches; at 20 inches, 24 inches; and at 24 inches, 30 inches. Counting a quarter circle, there were from 175 to 260 wet spots, or 700 to 1000 for each bubble.

It was evident that the force throwing these drops of water such great distances was not the air pressure inside the bubble. When the bubble burst the attraction of cohesion of the water composing the film acted to re-unite the distended watery molecules and, as the shortest distance between two points on the circumference of a sphere is measured on the great circle that joins them, the re-uniting molecules took that route, traveling over the spherical surface of the bubble, and when a number of them met and formed a drop, all the molecules were attracted with a certain force. The tangential components of these cohesive forces, acting in the substance of the spherical film and at right angles to the bubbles' radii, neutralized each other, while the centrifugal components united to shoot the drops away from the centre of the late bubble, in the direction of the prolongation of the bubble's radii, and they fell in a wide circle, as already stated.

This is a true statement of the phenomena of the effect of surface tension on a soap-bubble. By what stretch, by what torture, of the imagination can these phenomena be brought into identity or even the least resemblance with those of the placid floating of the greased needle upon the compressed surface of the water in the tumbler?

Mr. Charles T. Durell in an article in the Mining and Scientific Press of September 18, 1915, entitled 'Why Is Flotation?', discusses the rising of a bubble through a liquid and says: "Surface tension causes the molecules of the liquid to form a film around the bubble and remain with it to the exclusion of like molecules during the time the bubble remains in the liquid. To all intents and purposes, this film is seen to be the same as if it were a membrane of some solid. The air in these bubbles can no more come in contact with the liquid through which it is passing than it could were it inside a toy-balloon, for instance. The bubble may be said to be enclosed in a 'liquid skin'." As a proof of his argument he cites in a footnote the following: "A striking experiment to show these liquid films is as follows: To a beaker partly filled with a colorless oil, add a small quantity of permanganate solution. Blow air through a finely drawn-out glass

tube into the permanganate solution now on the bottom of the beaker. Air bubbles enclosed in the colored liquid film rise through the oil and break at the surface, because of the expansive force of the gas. The colored water drops back through the oil exactly in the same manner that a balloon, bursting, drops to the earth."

With these instructions the following experiments were made: A layer of water, half an inch thick, colored dark blue with a dye not soluble in kerosene, was put into a tumbler and three inches of white kerosene poured upon it. With a medicine dropper having a rubber bulb and a $\frac{1}{16}$-in. hole in the end of the glass tube, bubbles of air were blown into the blue water, the end of the glass rod resting on the bottom of the tumbler. At first the pressure on the bulb was made very gentle, the idea being to have the bubbles as small as possible. As many as 200 of these tiny bubbles were blown and they rose to the surface and formed a group. Some burst, some were incorporated with others, and finally, of course, they all burst. Every one of these 200 bubbles burst within a circle of half an inch, and that circle from the time of the first bubble until the last one, was not free from bubbles, one touching another and all forming a single compact group; but at no time, in the strong sunlight, was there the slightest trace of blue in the circle nor anywhere in the kerosene. The upward bound bubbles were perfectly white and there were no return passengers. The bubbles had no films but were simply holes in the water. When they came to the joint surface of blue water and kerosene, they slipped into the kerosene, made holes in that, and burst at the surface with no trace of a film.

Then, with greater pressure on the bulb, larger bubbles were blown, and with them, small quantities of the blue water were forced up into the kerosene. When these came separately the air rose to the surface and the water dropped back but where they came together the air buoyed the water up to the surface where the air escaped and the blue water sank through the kerosene and disappeared. With greater pressure the bubbles became still larger, as did also the size of the drops of water forced out with the air. Where trapped together the larger masses of air and blue water joined and rose to the surface, as a single entity, sometimes very rapidly and sometimes very slowly. But in no case, whatever the size of the constituent parts, was the air-bubble blue. There were never any water-films. The rising combined air and blue-water drops in the cases of the larger bubbles were in shape as if the bubble were sitting on a tiny blue feather bed. In every case the blue water was below and the white bubble above and the bubble was pulling the drop to the surface. Sometimes the drop was too heavy for the bubble to float and both sank to the water layer and remained stationary until the drop merged in the blue water and the bubble was released.

When the smaller bubbles rose to the surface of the kerosene they did not break as quickly as in water but seemed to strike against the under side of the surface stratum and rebound downward and moving over to the edge of the tumbler. On nearing the glass they seemed to rise as if attracted upwardly, like the part of the surface stratum around the edge under capillary attraction.

Some other interesting phenomena of capillarity were noticed. In the blue-drop-kerosene experiment the sides of the glass were wetted by the kerosene, even below the joint surface of the liquid; but notwithstanding this fact there was observed the concavity of the blue water under the oil, seemingly warranting the belief that the attractions between the water and the glass took place through the intermediate film of oil.

With a body of mercury, a glass tube pushed below the surface showed a rounded surface of mercury within the tube, with no capillarity, the rounded surface being due solely to surface compression. With the tube floating in the mercury the level of the outside mercury was exactly the same as the top of the rounded contents of the tube; but when the tube was pressed down into the mercury the level of the mercury in the tube was lowered. It seems likely that the indentation of the floating needle, and the lowering of the level of mercury in the glass tube are both due to the resistance of the surface compression to the entrance of foreign bodies.

In the experiment of the blue water, the bubbles, and the kerosene, we come most unexpectedly upon flotation, or its counterfeit. If it is flotation, like the mineral flotation, how is it to be accounted for? If it is different, what is the difference? Will an explanation of the blue drop-kerosene flotation be that of mineral flotation, or will it help in that direction? There is surely an attraction between the air-bubble and the blue drop, or why should they stick together? The blue drop is heavier than the kerosene and the bubble of air lighter. One pulls up and the other pulls down. Why do they not separate unless there is a positive molecular attraction between them? Why does the bubble, resting upon the blue drop, buoy both to the surface of the kerosene, except for some molecular attraction between blue drop and bubble? Where this attraction is manifested, even slightly, it is helped by the static pressure of the liquid medium in which the flotation takes place.

The great unsolved problem in flotation is the identity of the forces that do the floating. Some say that it is surface tension, some electricity, and some molecular attraction between the air-bubbles and the metallic particles; and there is always the mystery as to exactly the part played by the oil. In this article it is intended to show that there are certain molecular attractions between widely different substances which would seem to be nothing more or less than the force of cohesion acting at sensible distances, but for the circumstance that such an interpretation runs counter to our preconceived opinions as to molecular attractions; but these attractions are shown in this article to exist between glass and oil, between glass and water, directly and

through an intervening film of oil, between glass and air, and between water and air. The impression remains that a thorough examination of our preconceived opinions may show that they are fallacious.

There are strong reasons for believing that the state of science today is not unlike that of learning at the end of the 12th century, at the time of the great awakening, when the world dropped the scholasticism of Rome and went back to the philosophy of ancient Greece. We have lost the faculty of studying phenomena, we are ignorant of the first principles of logic, and we have degenerated into mere juggling with names.

Proof of this indictment is found in Vol. XXIV of the Encyclopedia Britannica, at page 401-2, where it is stated that the passage of electricity through liquids had been explained as a transference of a succession of electric charges carried by moving particles of matter or 'ions.' Then it was discovered that the moving particles that carried the electric current were much smaller than the atoms of hydrogen, and they were re-named 'corpuscles.' They enter into the structure of all matter. The only known properties of these corpuscles are their mass and their electric charge. There is reason to believe that the whole apparent mass is an effect of the electric charge. "The idea of a material particle thus disappears and the corpuscle becomes an isolated unit of electricity—an electron." This is a typical 'scientific explanation.' It starts out inventing the word 'ion', which it immediately re-christens 'corpuscle' and then 'electron,' and the only meaning that can be extracted from the argument is that electricity is supposed to be made up of units, a purely gratuitous assumption. Here is another on the same page 402: "Maxwell and Hertz showed that the velocity of propagation of light and electro-magnetic waves was identical and that their other properties differed only in degree. Thus light becomes an electro-magnetic phenomenon. But light is started by some form of atomic vibration and to start an electro-magnetic wave requires a moving electric charge." Here are three sentences all fallacious.

The peculiar tendency of the human mind which substitutes empty names for real phenomena and then plays with the names is the same that makes religious peoples worship idols instead of fixing their minds on principles. It is easier. A pilgrimage to a shrine where one may worship a rag, a bone, or a hank of hair, and be absolved, is less trouble than leading an exemplary life. So that when the question is asked "Why does a drop of water that falls upon dust take the form of a sphere?" it is easier to say "Oh, surface tension" and let it go at that than to think about it. It is all very well to say that a snark is a boojum, if you first define your boojum: but when you scratch the boojum and find the same old snark the pursuit of knowledge seems in vain.

The general subject will be continued with a discussion of electricity and magnetism, explaining their phenomena in terms of molecular attraction and the undulatory theory of light with the hope that some real and adequate solution may be found as to the problem of the identity of the forces that effect flotation.

Differential Flotation at Broken Hill

*The new zinc plant erected by the Sulphide Corporation at its Central mine, Broken Hill, is now at work. The principal feature of the works, which has a capacity of about 4000 tons per week, is the adoption of the Hebbard Harvey under-drive machine in place of the original Minerals Separation apparatus. The plant treats tailing from the lead mill, and the aim is to extract the lead remaining in the tailing after table concentration. The pulp is brought by elevators from the mill to the zinc-plant boxes, into which a small quantity of eucalyptus or other suitable oil is introduced. These boxes are fitted with special stirrers to agitate and aerate the pulp, creating a froth which is really a lead concentrate. Having removed all the lead possible by this means, the pulp passes to other boxes where sulphuric acid and oil are added. Agitation and aeration take place as before, and the zinc blende is recovered. There are 10 boxes, three for lead and seven for zinc.

The feed averages about 4.2% lead and 18% zinc, while the lead concentrate assays 57% metal. The residue from the first three boxes assays 3% lead and 18.5% zinc. The zinc concentrate assays 6% lead and 47.5% zinc. The residue assays 1% lead and 2% zinc.

The mill superintendent, R. J. Harvey, states that not only is the process worked in the cold, that is, the use of steam has been discarded altogether, but that it is possible to extract an additional 15% of lead and silver as compared with the process previously in use. Before, there was about 10% more lead mixed with the zinc than is the case now.

There is also another not unimportant factor to be borne in mind: the new plant will probably enable the fine tabling in the lead mill to be discarded. The rhodonite forms the chief difficulty in tabling, as its gravity is about midway between zinc-blende and galena. Flotation gets rid of all gangue, including rhodonite, and there is, therefore, a clear-cut issue between the two sulphides in the subsequent tabling operations.

DURING January the Mint at San Francisco received 221,392 oz. gold and 237,440 oz. silver in various forms. Coinage amounted to $6,140,000 in double eagles. Coin, bullion, etc., on hand at the end of the month totaled $365,017,927.87.

Industrial Opportunities in Siberia

By C. W. Purington

*ONE of those literary gems found in the old-time school-books relates that four blind men attempted to describe an elephant after having become familiar with this animal solely by the sense of touch. As nearly as I can remember, one referred to it as a tree, one a blanket, one a rope, and the fourth a wall.

The anecdote may serve to illustrate what impression four tourists from a foreign land, having no previous knowledge of the Russian empire, its customs or language, might derive from visits respectively to the Chukotsk peninsula opposite Alaska, to the cities of Petrograd and Warsaw, to the Russian Riviera in the Crimea, and to the cotton-fields of Russian Turkestan.

One characteristic explains some of the otherwise incomprehensible features of that hitherto mysterious land of Russia. The spirit of the Russian empire has been developed in the flat lands. The Russian does not understand the mountains. Neither does he understand the sea. As the Spaniard builds his village on the hillside, so the Russian builds his settlement on the river-flat. Trekking east on his never-ending trail, the Russian finally reached the Pacific. Two hundred years ago he made an attempt to cross it, but it finally baffled him. I give full credit to those intrepid men of the 17th and 18th centuries who carried and maintained the Russian flag in Alaska, even on the Yukon river, and established a Russian colony at Fort Ross in California before the days of '49.

Daring Russian traders built and outfitted their tiny ships at Petropavlovsk on the peninsula of Kamchatka two hundred years ago, and made voyages of two years' duration to the Alaskan shore after the sea-otter. Russian axe-heads have been found on the beach of Resurrection bay, the terminus of the Alaska railway, and it is said that Russian brass *ikons,* or sacred images, of antique manufacture have been cleaned up on the tables of the gold-dredges in the Klondike. But those *ikons* probably antedate the discovery of gold in the Ural, in the middle of the 18th century, and the gold of the Klondike was to await its allotted time.

Baranof and the Russian-American Company remained the dictators of Alaska until the sale to America. The Alaska Commercial Company succeeded to the trade. The Russian retired, leaving only the lone churches and the desolate hamlets on the Alaskan coast, and on the shores of the Anadir, Kamchatka, and the Ochotsk seas.

But if the Russian retired commercially, he still kept up his exploration of the Pacific border of Asia, and the pioneer Muravief Amursky succeeded in acquiring from China those vast and fertile regions known today as the Pacific Coast and Amur provinces. Nikolaievsk, Habarovsk, and Vladivostok were founded about the time of the discovery of gold in California, but remained villages until the coming of the railway. The most modern and prophetic monument I have ever seen is the colossal bronze statue of Muravief Amursky on the palisades of the city of Habarovsk facing that mighty river, the Amur. Behind him is Manchuria, and before him lies the Ussuri province, nearly as large as California, and rich in timber, grain lands, and minerals. At his feet is being constructed a steel railway-bridge two miles long, and every day the Amur railway is coming, coming from the north from Blagoveshensk to join the railway that connects with Vladivostok, 400 miles to the south.

Each year more ships of the Volunteer Commercial fleet carrying the Russian flag are to be seen on the Pacific, bringing goods from Odessa, and carrying them

*Abstract of an address before the Boston City Club.

as far north as Anadir, less than 250 miles from Cape Nome. Thus it appears that the Russian is beginning to take notice of this thousands of miles of sea-coast on the Pacific, and so far as possible the Government is assisting development by lenient customs regulations. No duties are imposed on machinery entering any Pacific Siberian port, and at present all articles are free of duty that enter Siberian ports north of Lat. 54°. Thus a Havana cigar entering Siberia through Ochotsk and transported 500 miles on sleds may be bought today at Yakutsk on the Lena river at a less price than in Boston.

I have said that Russians do not like the mountains, and this fact to some extent accounts for the lack of the development of the gold-quartz mining industry in Siberia. But we must not forget that those long-distance adventurers, the Siberian placer-miners, were mining gold at the rate of over $5,000,000 annually in the Yenesei forest at 58° north latitude before the discovery of gold in California; nor should it be forgotten that a gold stamp-mill was operating at Bereozovsk in the Ural mountains at the time of the American Revolution.

The industries commenced in Siberia are mainly those of a pastoral and agricultural character. The butter export business from Omsk, Novo-Nikolaievsk, and Barnaul in West Siberia now amounts to $20,000,000 annually. Much of this butter goes to England by way of Denmark. This business has apparently only commenced. It has all developed within the past 10 years. It is said that this butter is already beginning to find its way as far as Mexico. I can bear evidence that it is of excellent quality, as I have used it for the past two seasons, in one-pound tins. Under ordinary conditions the butter is transported to Riga on the Baltic sea in refrigerator-cars, a distance from Omsk of 2000 miles.

My friend August Heid of Chicago has been at work for several years as manager of the business of the International Harvester Co. in East Siberia, building up a business in agricultural machinery. This machinery is shipped from Portland, Oregon, to Kobe and thence to Vladivostok, to be there distributed to various centres such as Harbin, Blagoveshensk, Habarovsk, and the Trans-Baikal region, as far as Irkutsk. There it comes in competition with freight-rates from New York and Libau. It is a common sight in traveling on the Vladivostok-Habarovsk branch of the Trans-Siberian railway through the fertile Ussuri valley to see American reapers, harvesters, traction-engines, and mowing-machines used by the small peasant-farmers. Please do not, however, get the idea that this business was started without difficulty. The Harvester company sends no young Americans into that country who cannot speak the Russian language. That is the first step. In addition to this accomplishment, these young salesmen must have infinite patience, must be able to take long rough journeys by Siberian cart and sledge, must be able to live largely on tea, black bread, milk, eggs, cucumbers, and soup. They must be able to sleep and pass days at a time in vermin-infested huts, without fresh air in winter time. These, after all, are mere personal difficulties and are surmountable. What appears nearly insurmountable are the difficulties of convincing the people of their need of a new article. I enlarge on this feature here, as the Harvester company has initiated its business by establishing actual working exhibits of its machinery. Small traveling shows, similar to a country circus, were sent from village to village both in European Russia and Siberia, with a full equipment of tents, wagons, etc., and types of the machinery useful to the people. Working tests were made before the assembled villagers until the people were convinced that such machinery would be useful to them.

The Siberian peasant is emphatically "from Missouri." He must be shown. The only way to sell him your wares is to show him how they work. Curiously enough the best purchasers hitherto of American agricultural machinery have been what may be called the outside religious sects who, or whose ancestors, were exiled to Siberia. Of these the Malakans, who live in the great grain region of the Zeya valley surrounding Blagoveshensk on the Amur river, are the most notable. A more curious sect are the Skopsi, who live in an extremely fertile region surrounding the town of Yakutsk. Yakutsk is on the Lena river, some 1200 miles in a straight line north-east of Irkutsk, the nearest railway point, and as the traveler goes, nearly 2000 miles. It is in the latitude of the Great Slave lake of Canada. In October 1914 I met two Englishmen who had just come from Yakutsk, where they had purchased a large quantity of mammoth ivory. They informed me that the Skopsi are able farmers and almost without exception use modern agricultural machinery.

I do not think it an exaggeration to say that the grain resources of Siberia are beyond comprehension. Parallel with these resources are the live-stock possibilities. The number of horses in the Russian empire is estimated at 35 millions as against 24 millions in the United States, sheep at 80 millions as against our 50 millions, and cattle at 51 millions as against our 59 millions. I am safe in saying that a considerable proportion of the cattle enumerated are in Siberia. One must bear in mind that Siberia possesses numerous pastoral tribes, such as the Kirghese and Bashkirs of West Siberia, the Kalmucks and Buriats of Central Siberia. The sole subsistence of some of these people comes from their flocks and herds. The Kirghese are perhaps the nearest modern representative of the pastoral peoples of the Bible. While coming from the Lena in the fall of 1913 my automobile was stopped for some time to allow the passage of the herd of several hundred cattle from Mongolia, 1000 miles away, that were being driven to the river to be transported by barges a distance of another 1000 miles to Bodaibo, the centre of the Lena gold mining district.

The Lenskoi company, with which I happen to be

AROUND THE SAMOVAR.

ALLUVIAL MINING.

connected at the present time, operating 1000 miles north of the railway at Irkutsk, sells annually from 3 to 4 million pounds of beef to its workmen, about 7000 in number. This beef on the hoof comes by barges in summer to Bodaibo from Yakutsk, several hundred miles to the north, and in smaller quantity from Mongolia. It may be mentioned that frozen meat sells at Bodaibo at about 9 cents per pound in winter and fresh meat at 10c. in summer.

During the year 1907 and following I was engaged in conducting a small mining enterprise near Nikolaievsk on the Amur river. An average catch of 10,000,000 salmon of 10 lb. each is taken at this point annually. For 30 miles above and below the town on both banks of the river nets are extended across the water for about 1000 ft., and about September 1, when the short salmon-run is on, the river presents a lively sight. I have never been fortunate enough to be in town when the actual run happened, but it is said that the five-mile width of the river is transformed from the black water to a shining plate of silver from the flashing of the millions of salmon-backs.

Practically no canning is done; the fish are either bought by Japanese schooners, which bring their own salt from Hakodate, or frozen and shipped to Europe in refrigerator-steamers. Some 40 graceful Japanese boats lie at anchor off the town at this time, and several big freighters from Hull and Hamburg are near-by. Previous to the War I understand that cargoes of salt were even brought from Germany to Nikolaievsk, such was the demand for this commodity.

You will see by the map that Siberia possesses nearly 6000 miles of coast-line bordering the Pacific and its inland seas. This coast is comprised between the Korean boundary and Behring Strait. Many rivers, the Amur, the Ud, the Lantar, the Okhot, the Kamchatka, and the Anadir, and hundreds of small creeks and streams, debouch on this coast. Three of these exceed 1000 miles in length, and the Amur 2000. Salmon, sturgeon, porpoise, herring, and a multitude of other fish swarm in these waters. I have no need to tell New England men of the whaling industry of the Ochotsk sea, celebrated in New Bedford legends. But if the whales are largely gone, the salmon are hardly touched and one may look for great canning industries eventually on the Ochotsk shore of Kamchatka, to say nothing of the herring fisheries of Chukotsk. But you will say that this is a frozen coast and useless. In this you will be entirely wrong. The coast extends from 42° to 67° north latitude, or, let us say, from the northern boundary of California to Behring Strait. Any house dealing in mining supplies will tell you that they will deliver 10-ton castings at Nome, in an open roadstead, by lighters through the surf during July, August, and September. There is no worse sea exposure in the world than Nome beach, surely nothing worse on the Siberian coast to which I have referred. So much for the northern end of it.

On the southern end you may walk through fields of poppies and tobacco, bordering the shore. You may pluck orchids amid groves of cork and black walnut trees. Within 30 miles of Vladivostok on the shores of American Bay, you may sit at night in camp listening to the droning of semi-tropical insects, and fascinated by the indescribable beauty of the glow-worm's lantern.

Russia's finest harbor on the Pacific, as yet practically undeveloped, lies 300 miles north of Vladivostok, namely Imperial. For the past six years the Oriental Timber Company of Australia has been shipping tamarack and spruce lumber to Australia from this harbor. Navigation the year round can easily be maintained from both Vladivostok and Imperial harbors. Men like Capt. Bartlett, who tells me that he would hesitate to take a cargo from San Francisco to the mouth of the Lena through the Behring Sea, would probably consider it a pleasant excursion to take a steamer from Boston to Vladivostok in the month of December. Mail service by the Russian boats, *Riazan* and *Simbirsk*, and the Japanese boat *Hozan Maru* is maintained all the year round in connection with the Trans-Siberian express, from Vladivostok to Tsuruga, in Japan. To say, therefore, that Siberia does not possess all-the-year-round ports is incorrect.

The Russian government, ordinarily a slowly-moving body, occasionally acts with unparalleled suddenness. It has recently done so. It has transformed a drink-

sodden peasantry into a virile and watchful people. The flower of Russia is in Siberia. Its population of 30,000,000 is steadily increasing. It is always the experience that the best men and women go to the frontier. These people need your commodities, they need your saw-mill machinery to cut their vast forests of tamarack, your Studebaker wagons, your motor-cars and motor lorries to get about and to haul their goods. Siberia with its 15,000 miles of navigable river-ways needs your flat steamers, and your steel plates for barges. Your machine-tools, your cement-making machinery, your ten thousand mechanical contrivances, your excavating and conveying machinery to dig ditches, to deepen rivers and harbors, to compete with hand labor in building automobile roads through the interminable forests. Siberia needs your concentrating machinery to work the lead and zinc ores of the Trans-Baikal, the Altai, and the vast low-grade copper deposits of the Sayan ranges on the border of Mongolia. Your rough and practical clothes for frontier life, rubber boots, leather boots and shoe-packs, your Levi Strauss overalls, your Mackinaw shirts, even your fur-coats, sleeping-bag, and reefers. Strange is it not? You cannot buy a decent fur-coat in Siberia, or a practical one for work. This, in Siberia the home of the bear, of the fox, and the millions of sheep and horses. Siberia has the furs, but she has not yet made the clothes. Absurd as it may seem, the only two American commodities, outside of agricultural machinery, in general use in eastern Siberia are Taylor's fly-paper and Carnation condensed cream. What has Siberia—in fact, what has the whole of the Russian Empire, to drop into the vernacular of the moment, been up against? She has been up against the German. And she has been up against the German good and hard. Russia was Germany's best commercial colony.

In my various trips through the Siberian communities I have frequently inspected small steam and electric installations, and have found the electric ones almost without exception of German manufacture, while the steam units are usually of the German locomobile type. In the city of Vladivostok a large and handsome building stands facing the harbor on one of the main streets. The entire building was occupied by a great electrical firm of Berlin. From this office the company directed not only the civil installations throughout the Primorsk or Coast province of Siberia, but also the principal electric installations of the Russian government. In order to install a 450-kw. American generator at Nikolaievsk in 1910, special permission was necessary from a firm of German manufacturers. Is this incident likely to be repeated? I think not. The building of that German company to which I refer is, I have no doubt, boarded up as tight as the German embassy at Petrograd and the German staff of the company are in safe-keeping until the close of the War.

I can give one example of the former use of German electric machinery by a gold-mining company using some 20 generators and over 100 electric motors for mining purposes in connection with five hydro-electric plants that are almost exclusively of German manufacture. This company has now decided not to purchase another pound of German machinery of any shape or description. Centrifugal pumps, direct acting pumps, hoists, electric and steam industrial locomotives, excavating and conveying machinery are subject to the same comment. Fuse, caps, quicksilver, special steels, tools of all descriptions have been for years purchased by the Siberian gold mining companies from Germany. The Russians say "Never again."

Let American manufacturers abandon now, once for all, the idea that they can sell any more machinery to Russia by means of German agents or German affiliations. Russia is finished with Germany, for a decade, and perhaps for longer.

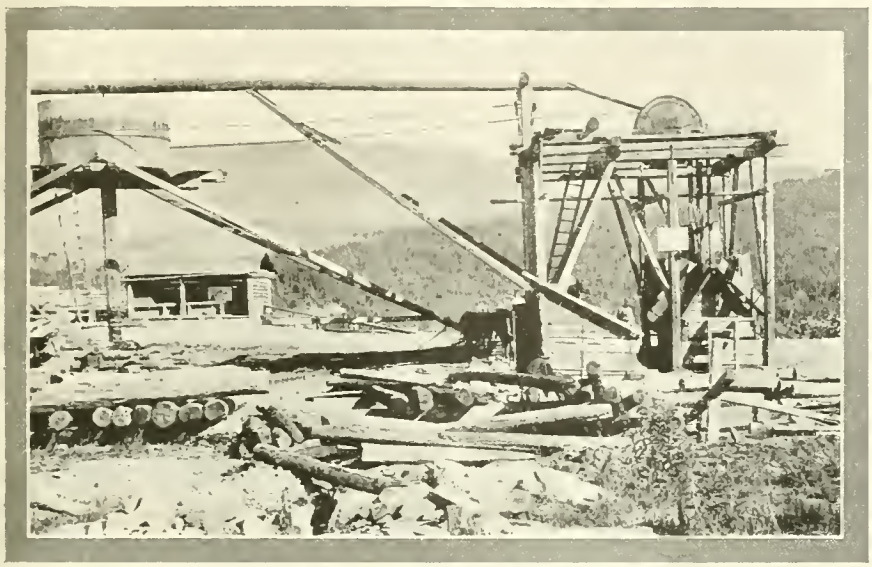
In Vladivostok in 1908 I purchased a few tools that looked as if they were American: claw-hammers, railway-lanterns, monkey-wrenches, small jacks, etc. A superficial inspection showed that these were not of American manufacture, but imitations. They all proved almost worthless. These were the celebrated 'Hamburg seconds'; remember that name, good enough for the Far East and for South America, where the American manufacturer does not penetrate but where his goods are in demand. The goods in this case were supposed to fool the Chinese, but in reality they proved useful as models by which I had similar tools made locally, roughly, but of good material.

In the eastern cities of Vladivostok, Habarovsk, Blagoveshensk, and Nikolaievsk on Amur, were the large department-stores of Kunst & Albers of Hamburg. This firm, possessing many Russian shareholders, was practically in the same commercial relations to the Russian Far East as the American trading companies to Alaska. The Rickmers line of steamers from Hamburg, and boats chartered by the firm itself, brought European goods every year to stock for the needs of the country. The firm maintained its own German club at Vladivostok. The stores are closed, the club is closed, the staff is in safe keeping. When the War is over the firm will be Russian in fact as well as in name, and will afford a market for American goods.

The Russian firm of Churin, which is the successor of that pioneer of Siberian trade, the Cape Cod merchant, Enoch Emery, has always been a powerful competitor of Kunst & Albers, but the management of the former was not so enterprising. The goods were of the rougher sort, and of good quality, for I have myself paid them many thousands of rubles on behalf of mining companies. But American goods they knew not, and apparently could not obtain. Few of the employees of this great Siberian firm, which has even stores at Anadir, opposite Cape Nome, could speak anything but Russian. Would that we had today in America more men of the type of Enoch Emery, that indefatigable pioneer, of the type of Captain Niebaum of San Francisco, and of the former New England traders of Petropavlovsk, hustlers who are willing to face the East and to learn its secrets, in place of that self-satisfied and small-scale individual whose

ideal of foreign commerce is limited to correspondence with foreign agents whose faces he has probably never seen, whose language he cannot speak, and of whose business methods he is ignorant.

The Keystone Driller Co., of Beaver Falls, the Allis-Chalmers Co. of Milwaukee, the Sullivan Machinery Co., and the Bucyrus Steam-Shovel Co. have, it is true, found a good agency at Petrograd, a Russian firm whose manager was for several years in America. But these agencies are difficult to find. The Singer Sewing Machine Co. is probably the most notable example of a firm that has established itself in Russia, and others that may be mentioned as having their own organizations are the Westinghouse Air Brake, the Eastman Kodak, and the Walkover Shoe companies.



A SIBERIAN HORSE-WHIM.

Typewriters, phonographs, scales, office fixtures, small machinery, and supplies of all kinds of American origin are sold by agents, when they are sold at all. Competition is severe, and the European having his representatives in the country, his Russian office established, his banking correspondents close at hand who thoroughly understand the long credit system, and who are ready to make him advances, this European, I say, gets the business.

I would here say a word about England. England, like our own country, has been asleep. It is true she has banking arrangements with Russia, whereas we have none. I believe that her banks will greatly extend their operations in the Russian Empire after the present war, and long credits will be easy to arrange. The commercial arrangements of English houses have, however, been far inferior in Russia to those of German, Danish, French, and Swedish firms. But the England of after the War will be a far different one commercially from the England before the War, and she will offer a keen competition with America for Russian and Siberian business. Moreover, she has the inestimable advantage of possessing ships, which we have not.

At the National Convention for Foreign Trade held at St. Louis on January 21, John J. Arnold, vice-president of the First National Bank of Chicago, said that there should be an amendment to the Federal Reserve Law which would give the banks of the United States authority to use 5% of their capital stock in forming banks in foreign countries. In connection with this, Mr. Arnold spoke of the desirability of subscribing to loans issued in these countries. Not only the Government of Russia, but the municipalities of that country, such as Moscow, Kief, Ekaterinoslav, Baku, Harkof, Saratof, Odessa, cities in the midst of a great agricultural district, in some of the finest coal and petroleum districts of the world, have issued loans of from one to five million dollars and even more which have been plentifully subscribed in London during the past five years. Even these cities in the old part of Russia, must continue to build, and to extend railway, tramways, city improvements, water and drainage systems, and they will need foreign money. Why should not these loans be subscribed in New York and in Boston as well as in London?

AT HEADQUARTERS.

Like the old Scotch lady who refused to show the conductor her ticket because she did not wish him to know where she was going, the American banker and the American merchant have apparently carried their caution of doing business with Russia to the extent of childishness. The credit of the Russian Empire needs no apology from me. The establishment of the Russian American Bank at Petrograd, with branches in the principal Russian and Siberian cities, offers one of the world's great banking opportunities, and would be of unquestionable assistance in the establishment of American trade on a permanent basis.

As regards stock exchange transactions, the Russian bourse labors under legal disadvantages, as official dealings are limited to Russian securities exclusively. I have, however, reason to believe that a change in these restrictions is under consideration, and one may look forward to the day when shares of international standing may be dealt in as freely at Petrograd as at London.

I have got rather away from Siberia, in trying to impress on you that you are not dealing, so far as getting your money from the Russians, with a frontier country, with a wilderness, not with wild men dressed in skins, but with a country far advanced in development and in finance, probably farther in what pertains to international finance and exchange than you are yourselves.

By the trade-routes that I have pointed out, it is likely that you can supply Eastern Siberia with commodities at a cheaper freight-rate than they can obtain them at Petrograd, Moscow, or from western Europe. The difference is that between a rail haul of at least 5000 miles and an ocean freight of not more than double the distance.

I have been responsible for the importation of some $200,000 worth of American machinery into East Siberia, including gold dredges, machine-shop equipment, wagons, motor-vehicles, and boats, excavating machinery, wagons, harness, clothes, etc., and I am compelled to say that the knowledge possessed by American manufacturers of how to pack goods for foreign shipment, and their knowledge of foreign shipping routes and shipping rates is primitive in the extreme. There is a crying need in this country of school-courses, not only in Russian, Spanish, French, and German languages, but also to teach commercial geography, and the commercial methods used by our world competitors.

When I was a boy in Boston I used to take delight in frequenting an establishment known as the Windsor theatre, celebrated for the hair-raising dramas there performed. One of these, as I remember, was called 'In Darkest Siberia,' or words to that effect. I am afraid that most of us derived our impression of that country from the information afforded by similar productions. I cannot give you impressions of Siberian prisons, as I have never been in one, excepting one that I gave orders to have built to confine certain obstreperous workmen while they awaited the arrival of a steamer to take them to the nearest police-station. I have been at the Government mines in the Nerchinsk districts where convicts are employed, and beyond a certain feebleness of activity, which would not be permitted on a privately-owned gold mine, I did not notice any special difference between the treatment of these men and of other laborers. This was a gold-gravel drift mine, where the convicts worked underground and most of the surface-men were Chinese. The most evident feature was apparently an understanding between the convicts and the Chinese business man on the hoist by which the latter purchased gold panned surreptitiously by the convicts in the drifts on the night shift. The fact is that convict labor does not pay in Siberia, and although convicts are sometimes offered to the mine-owners at a normal wage by the Government, free miners are always preferred at a considerably higher wage.

Our good friend Kipling refers in the 'Rime of the Three Scalers' to Siberian "mines of mercury, that loose the teeth in yer jaw." If Mr. Kipling can find a quicksilver mine in Siberia and get an option on it, I shall be glad if he will communicate with me. But if Siberia has no quicksilver, so far as known, it has other metals in abundance, and it may be mentioned that the mining world is now looking to Siberia as perhaps the greatest untouched field for gold, for copper, lead, and zinc. Russia gives the copper miner a bounty of five cents per pound over the market price outside the Empire, and within a few years it is expected that the mines of the Ural and Southern Siberia will add a considerable quantity to the world's output of copper. The simple introduction of the process of pyritic smelting in the copper mines of the Ural by Americans has transferred unprofitable deposits into important producers. Deposits of the disseminated copper type and other low-grade deposits that can be mined in open-cuts by the steam-shovel are being investigated. Figure to yourselves a mineral-bearing mountain system with peaks up to 12,000 ft. in height, three times as long as the entire north and south extent of the states of Utah, Arizona, and Sonora, and you will get an idea of the extent of territory in the Alatau, Altai, and Sayan ranges of Siberia, which remain to be explored. That entire belt is mineral-bearing, with volcanic rock associations; and history shows that the base metals have been worked by primitive peoples throughout this backbone, so to speak, of Asia for a period commensurate with the age of the Buddhist religion.

The Russian Empire comprises one-seventh of the land area of the globe. Russia in Europe has 2,000,000 square miles, while Siberia exceeds 6,000,000 square miles, a total of over 8,000,000 as compared to the 3,025,600 square miles in the United States. The population of the Russian Empire is estimated at 170,000,000. The topography is that of great undulating plains, diversified by broad plateaus and mountain ranges. A number of large rivers drain the country, and there are extensive areas of fertile black soil, highly productive where tilled. There is an American consul at Vladivostok, and at a half-dozen cities in European Russia.

Smelting Flotation Concentrate

IN the November issue of *Teniente Topics*, the monthly publication of the Braden Copper Co., Chile, a member of the staff briefly outlines the development of the smelter from 1909 to the present time. Metallurgical difficulties have been many, but were overcome, in spite of being 6000 miles from the base of supplies. The plant now treats 350 tons of concentrate daily, yielding 60 tons of copper, during which operation 60 tons of coke and 10 tons of fuel-oil are burned, employing 350 men and 1500 hp. This quantity of concentrate is recovered from 4000 tons of ore crushed per day. The concentrate consists of 19% copper, 17% silica, 23% iron, 2% lime, 8% alumina, and 28% sulphur. It is sandy and slimy, and contains 20% water. Of the 350 tons of concentrate, about 215 tons is dumped from V-shaped steel cars into bins, which supply the nodulizing kilns. This concentrate is then fed to conveyor-belts, thence into kilns, heated by oil-burners to a temperature of 1750°F. In the kilns, the sandy concentrate is quickly heated by the burning of the oil, and also by the combustion of a part of the sulphur content, to a sticky consistence, in which state the rolling motion tends to ball it into nodules of varying size. The kilns are sloped an inch per foot toward the discharge-end, out of which the red-hot nodules pour onto an endless chain of cast-iron pans, which convey the product to hoppers ready to charge into the blast-furnaces. The nodules have about the same chemical content as the original concentrate, except that the proportion of sulphur has been reduced from 28 to 18%, and, of course, the moisture has been evaporated.

A by-product of the nodulizers is flue-dust, that is, a small proportion of the concentrate blown out by the draft in the kilns and caught in dust-chambers, removed, and hauled to the bins for re-treatment.

Another 50 tons of the original concentrate is sent to bins that discharge to the sinter-plant, of four units. Each unit is a concrete box, 4 ft. wide by 50 ft. long. In place of a top there is a cast-iron grate similar to that of a stationary boiler, but with smaller air-holes. An exhaust-fan is connected to the box, creating a strong down-draft of air through the grate. A 4-in. layer of raw concentrate is spread on the grate with an inch layer of saw-dust ignited with kerosene or gasoline torches, after the fan has been started. The saw-dust starts the combustion of the sulphur in the concentrate. This then continues to roast for an hour, when the sulphur is reduced to 12% and the loose layers are reduced to hard cake. The cake is broken into pieces six to eight inches in diameter and raked into cars that go to the blast-furnaces.

The remaining 85 tons of concentrate received daily is discharged into bins, thence fed by conveyors into cars directly to the blast-furnaces; this amount being smelted raw. Thus 62% is nodulized, 14% sintered, and 24% of the concentrate is reduced direct.

The two blast-furnaces are 25 and 30 ft. long, respectively, 4 ft. wide, and 9 ft. deep, with hollow-steel water-jackets. The furnaces are fed with a charge consisting of varying proportions of nodulized, sintered, and raw concentrates, together with converter-slag (containing 60% iron) as a flux, and coke as fuel. The proportion of coke to concentrates averages about 15%, and is dependent directly on the amount of raw and nodulized concentrates. This mixture gradually sinks in the furnace, becoming hotter and continually melting, until in the bottom it is liquid at a temperature of 2500°F., and runs into the settler. The matte, containing 45% copper, 30% iron, and 25% sulphur, remains in the settler until removed through a hole near the bottom and poured into the converters through a brick-lined launder.

The converters are of the Pierce-Smith basic-lined type. Each consists of a horizontal cylindrical sheet-steel shell 25 ft. long by 10 ft. diameter, inside of which is a lining 18 in. thick of magnesite brick. This material is not attacked by the chemical reactions in the converter, and consequently lasts for a long time, unless allowed to over-heat. The cylindrical converter-shell rests on heavy rollers, and can be revolved around its axis so as to empty its contents through a hole in the side when necessary. The converter is pierced by a horizontal row of blast-pipes through the steel shell and lining, for the entrance of compressed air. These holes are in a line parallel with the axis of the cylinder somewhat below the centre-line, and point down toward the bottom of the converter. A large hole in the top receives the charge of matte, and serves as a chimney for the escape of gases.

When ready to receive a charge, the converter is revolved until the mouth is under the end of the matte-launder leading from the settler mentioned; this position places the tuyeres at about the centre-line of the cylinder. A stream of matte is run by gravity into the mouth, until the converter is filled almost to the level of the tuyeres. There is also added a small amount of quartz. Compressed air at 10 to 12 lb. pressure is then forced through the tuyeres and the converter is revolved until the tuyeres are submerged about 12 in. under liquid matte.

The elimination of the iron and sulphur leaves practically pure copper as the only remaining constituent of the matte; after 12 hours of alternate blowing-in air and pouring-off slag a bath remains of 25 to 30 tons of molten copper. This goes into ladle-cars and is hauled to a receiver, which is simply a huge brick-lined kettle capable of lifting and pouring its contents into a line of moving cast-iron molds.

Queer Mine Accidents

By P. B. McDonald

In the Mining and Scientific Press of October 23, last a peculiar blasting accident was recorded in the Deadwood news-letter. Three men in the Oro Hondo shaft had lit the fuses of a round of 15 holes, and climbed into the bucket. Owing to a delay in starting the hoist-engine which was on dead-centre one man became excited, jumped from the bucket, his light went out, and the bucket was hoisted. His companions missed him, and grabbed the bell-cord, giving the signal to stop; but the man in the shaft, not knowing that, started to climb the bell-cord, thus giving another signal which carried the bucket and two men to safety on the 1500-ft. level. Of course the bell-cord broke, leaving the man in the midst of 15 holes, loaded heavily and about to explode. Getting in a corner he barricaded himself with planks and heard eight of the holes fired; he says he heard no more until his companions dug him out intending to take his remains to the undertaker. Aside from a few slight bruises, and a nervous shock, he was not harmed and in a few days was as before. The fault, in this case, was carelessness in not having kept the ladder extended to the bottom of the shaft. A somewhat similar case occurred in a gold mine at Grass Valley. The hoist refused to work, leaving several miners in a shaft among a round of holes with lit fuses. All but one of the men tried to climb the timbered sides of the shaft. That one, with a praiseworthy coolness, cut all the fuses with his knife, and succeeded in beating the round.

In another instance in the Lake Superior iron region, during the sinking of a vertical shaft, the bucket had been removed to enable the cable to lower timbers, etc., held with a chain. On one occasion when the empty cable was being hoisted, a miner caught hold of it, foolishly thinking to ride up the shaft by hanging from the end of the chain. Of course the cable swayed so much that he was dashed against the timbers, killing him.

At the Tioga mine, Bodie, Mono county, California, in 1879, a man escaped death in a remarkable manner. The story as told by a prominent mining engineer of New York, and verified by the man who was his foreman at the time of the accident, is as follows: Nine men of the night shift were being lowered in the cage down a vertical shaft; contrary to orders the hoistman in the engine-room did not throw in the clutch of the hoist in advance, but began to lower the cage holding it merely by the brakes, probably intending to throw in the clutch later. The cage fell rapidly, so that the hoist-man could not stop it; the amount of friction he was able to give it only served to keep the cable taut so that the safety-catches did not work. In fact, it would have been better had the cable broken, as in that case the safety-catches would have caught and stopped the cage. The cage and men fell 520 ft., went through a bulkhead of 8-in. square timber, and dropped 20 ft. into a dry sump. Six of the men were killed, two were mangled and crippled, so that they subsequently died of the injuries, but the ninth man in some miraculous way received only a few insignificant abrasions. When rescued he was speechless but not unconscious.

The same authorities vouch for the truth of the following equally marvelous escape. In early days on the Comstock Lode, a miner named Tom Oliver fell 170 ft. in the Yellow Jacket shaft, went through a 2 in. wooden platform into a sump of water, and was uninjured.

At a mine in Colorado, another engineer was being lowered in a bucket down a rough exploration shaft inclined at 75°. Ice had formed in the shaft, particularly on the peeled poles along which the bucket slid, to such a degree as to constrict the opening. The bucket caught and stopped, the cable piling up there. No one was within sight or hearing, and quick action was necessary. The engineer jumped out, clung to the timbers, kicked the bucket loose, slid down the rope into the bucket and rode on with nothing worse than torn hands. In a recent blast of 11 tons of powder at a gravel mine in Sierra county, California, the fume spread about so widely that four men were asphyxiated; and the smell of the fume was noticeable several miles away. Ten tons of the charge was black powder and one ton, the primer, was 40% dynamite.

Similarly a great many queer accidents take place around a mine; accidents in the hoisting, to engineers carrying transits underground, from electric trolley-wires, during roof-scaling, on ladders, in sumps, around steam, air and water lines, at loading-chutes, etc. Some are seemingly unavoidable, but others if better understood would not happen again.

Man is a social animal; is he also essentially a gambling animal? Is it true, as many allege, that fewer things would be done, fewer things ventured upon, were it not for the gambling chance of profit? Speculation, gambling, is looked upon as the risking of a little on the chance of making much. Without such an incentive, it is often argued, enterprise would languish and material civilization would forthwith decline. Is all this so? Does not the argument arise from a confusion of ideas? The spirit of enterprise is not quite the same thing as the gambling spirit. Properly viewed, enterprise is not the risking of little to make much. It is something better than that. The man who lays down a dollar hoping that the turn of the wheel will give him a hundred is risking a little on the chance of making much—he is gambling. If he got the hundred he would have done nothing for it. The man who spends his little on some invention, who puts his all in some business venture, who prospects for gold—none of these is gambling in the real meaning of that word. All of these devote to their task their labor and their intelligence—man cannot give more. The gambler despises labor; he seeks only, if by chance he may, to divert to himself the fruits of the labor of others. The gambler in whatever field he operates is but a parasite; he need not delude himself into believing that he is a useful member of the community.—*The Annalist.*

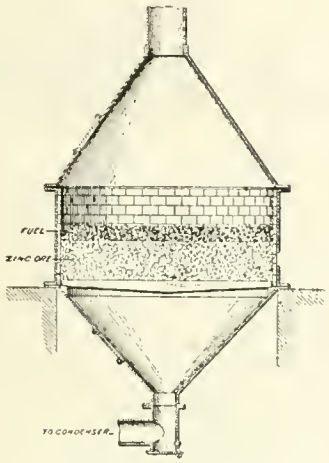
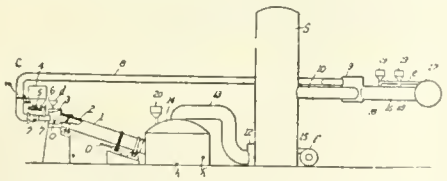
1,161,886.—Removing Cadmium from Zinc Ore. Gilbert Rigg, Palmerton, Pa., assignor to The New Jersey Zinc Company, New York, N. Y., a corporation of New Jersey. Filed July 27, 1915.



1. The method of removing cadmium from roasted or naturally oxidized zinc ore, which comprises superposing, the one upon the other, a layer of fuel and a layer of cadmium-containing zinc ore, igniting the fuel and passing a body of air through the fuel and then through the ore until the ore is raised to the reduction temperature of cadmium but not of zinc, and continuing the passage of air through the fuel and ore, for the removal of the cadmium, without substantial removal of the zinc; substantially as described.

1,160,621.—Process of Smelting Ores. John H. Klepinger, Milo W. Krejci, and Charles R. Kuzell, Great Falls, Mont. Filed January 21, 1915.



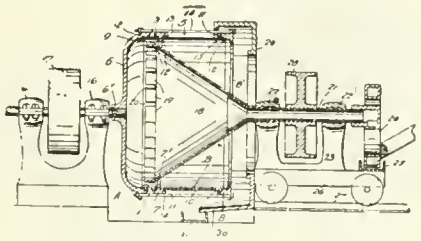
1. In the treatment of metallic oxids, the process of spraying a charge of the oxids in a finely divided state into a treatment chamber, surrounding the particles while in the chamber with a gaseous reducing medium, maintaining the temperature of the mixture in the chamber to effect a reduction of the oxids and a smelting of the metallic constituents of the charge while still in a finely divided state, precipitating the fused particles, causing the precipitated particles to advance under agitation and in the presence of a reducing medium to a suitable settling chamber, and finally removing the same from said last mentioned chamber.

Ore-Separating Process. Arthur J. Moxham, Wilmington, Delaware. Filed April 6, 1912, serial No. 689,038. Renewed January 22, 1915, serial No. 3836.

1. In the process of separating solid constituents of different specific gravities, first treating the solids by coating them with a definite percentage of material adapted to reduce the specific gravity of each of the solid constituents to a predetermined degree, and then immersing them in a liquid separating medium.

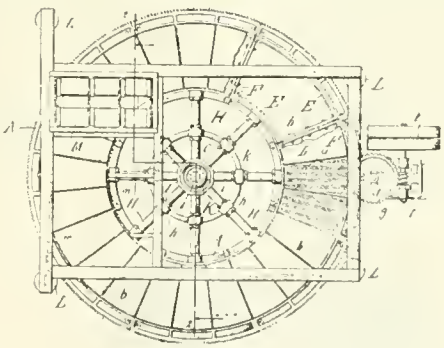
2. In the process of separating solid constituents of different specific gravities in a heavy liquid, first treating the solids to reduce the specific gravity of each of the solid constituents to the extent required to cause the separating liquid to have the desired specific gravity relative to the specific gravity of each of the solid constituents, and then effecting the separation of the solid constituents in such separating liquid.

1,160,550.—Gold-Saving Machine. John T. Voigt, Richmond Beach, Wash. Filed October 22, 1914.



1. In apparatus of the class described, a drum rotatable on a horizontal axis and having intermediate its length a cylindrical portion formed of an amalgamable material and circumferentially unobstructed, said drum being closed at one end and with an opening at the other end of less diameter than the aforesaid cylindrical portion, and means extending into the open end of the drum adapted to feed auriferous material directly to the inner peripheral surface of the drum, said means being at all times unconnected with respect to the drum and removable therefrom for cleaning the interior of the drum while the same is rotating or otherwise.

1,166,142.—Calcining, Desulfurizing, and Agglomerating Ores, &c. Franz Meyer, Englewood, N. J., assiguor to Dwight & Lloyd Metallurgical Company, New York, N. Y., a corporation of New Jersey. Filed November 9, 1907.



1. Apparatus for the metallurgical treatment of ores and the like, consisting of a receiving grate for supporting the charge, means for revolving the grate bodily about an upright axis, means for feeding the charge to the grate in a uniform layer, means for causing aeriform fluid to traverse the charge, and means for automatically removing the treated charge from the grate as it passes a predetermined point in the grate's revolution, said means consisting of a scraper located at said point and having a plow front which detaches the charge from the grate and a diverting abutment in the rear of the plow front; substantially as described.

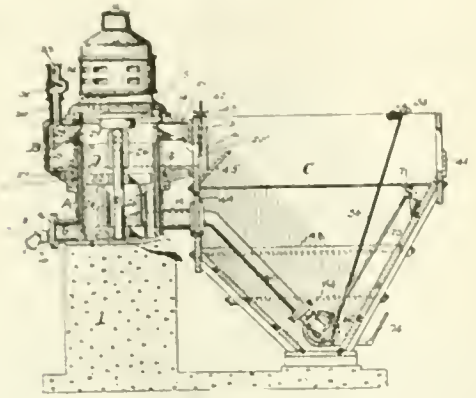
1,166,067.—Process for Separating Cobalt From Ores or By-products. Philip M. McKenna, Washington, D. C., assignor

to Chemical Products Company, Washington, D. C., a corporation of West Virginia. Filed September 25, 1914

1. The process of separating cobalt from a speiss containing the same, which consists in effecting fractionation by fusing the speiss with boron trioxid.

2. The process of separating cobalt from a speiss containing cobalt and nickel, which consists in fusing the speiss and boron trioxid and causing the nickel arsenid speiss to separate from the boric cobalt slag by reason of the difference in their specific gravity

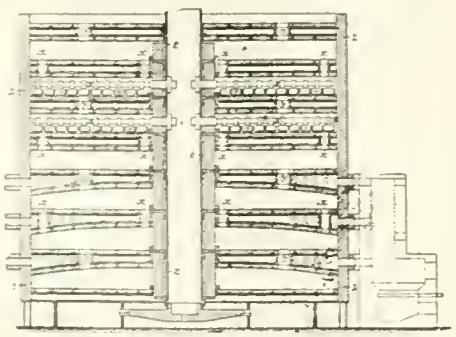
1,167,076.—Ore Concentrating Apparatus. Thomas A. Janney, Garfield, Utah. Filed August 10, 1914.



1. In a device of the class described, an agitation vessel, a separating box having admission and discharge chambers provided with admission and discharge ports respectively, admission chamber and discharge chamber circulation ports connecting said chambers respectively with the lower part of said agitation vessel, and means for moving an ore pulp upwardly in said vessel and into said box.

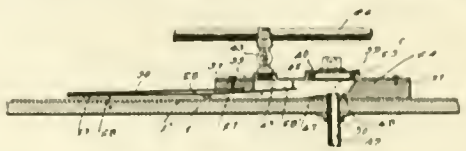
2. In a device of the class described, an agitation vessel, a separating box having admission and discharge chambers provided with admission and discharge ports respectively, admission chamber and discharge chamber circulation ports connecting said chambers respectively with the lower part of said agitation vessel, said separating box having an overflow lip, a duct connecting said vessel and box at a point above said overflow lip, and means for impelling an ore pulp upwardly in said vessel.

1,162,532.—Metallurgical Furnace. Utley Wedge, Ardmore, Pa. Original application filed May 3, 1911, Serial No. 624,792. Divided and this application filed July 11, 1912; renewed July 1, 1915.



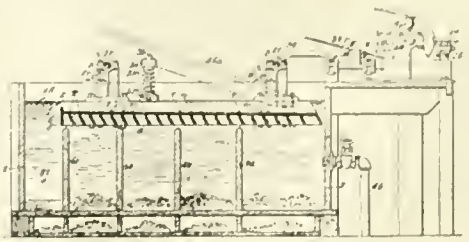
A furnace having superposed annular hearths some provided with discharge openings both at their inner and outer portions while alternate hearths are provided with discharge openings midway of the widths of the same, and a central rotating shaft having thereon rabble carrying arms projecting over the hearths, the rabbles on those arms which project over the hearths having inner and outer discharge openings being so disposed as to move the material from the middle of the hearth toward the inner and outer portions of the same, and the rabbles over those hearths which have the openings midway of their widths being so disposed as to move the material from the inner and outer portions of the hearth toward the middle of the same.

1,163,341.—Concentrator. John F. Isbell, Los Angeles, Cal., assignor to Orren Allen, Denver, Colo. Filed September 8, 1913.



1. In a concentrator, the combination with a concentrator table, of a cut-out device thereon, comprising a casing with a chamber, discharge means leading from said chamber, said chamber having an inlet at one end, a horizontal separator plate extending forwardly from the inlet of said chamber to direct the material passing below said separator plate into said casing, a supplementary horizontal plate extending above said separator plate and spaced therefrom to serve as a guide for the fluid passing over said separator plate, side walls extending divergently rearward from said cut-out casing beneath said separator plate, and side walls extending divergently rearward beneath said supplementary plate and spaced from the casing to form passages between the said plates, the casing, and the said last named walls.

1,160,502.—Ore-Jig. Frank Franz and Eugene R. Day, Wallace, Idaho. Filed May 8, 1914.



1. The combination with a clutch having a series of independent transverse compartments, a screen hung over the said compartments, the said screen being formed in sections of progressively different mesh, one of the said sections being provided for each of the said compartments, the said screen including slats on their under face that incline diagonally toward the receiving end of the screen, vibratory hanger devices from which the screen is suspended, and means for imparting reciprocating motion to the screen in a plane parallel with the diagonal angle of the screen slats.

1,165,692.—Process of Extracting Vanadium, Uranium, and Radium From Ores. Richard Bishop Moore, Denver, Colo. Filed October 7, 1913. (Dedicated to the public.)

1. The herein described process of extracting values from ores containing vanadium, uranium and radium, which consists in leaching the ore with a solution containing an alkali carbonate and an alkali hydrate, recovering vanadium from the solution, leaching the residue with an acid solution and recovering uranium and radium from the solution.

2. The herein described process of extracting values from ores containing vanadium, uranium and radium, which consists in leaching the ore with a solution containing sodium carbonate and sodium hydrate, recovering vanadium from the solution, leaching the residue with a hydrochloric acid solution, and recovering uranium and radium from the solution.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

MILLS OPERATING AND OUTPUT.—DELMONICO, EL PASO, ISABELLA.

Only three treatment plants were in operation on low-grade ore in January, all of the other mills being closed on account of repairs, change in method of treatment, or experiments being conducted to determine the best way to extract the gold. The production in January, as reported by the mills and smelters, is as follows:

Plant and location.	Tons.	Average value.	Gross value.
Smelters, Denver and Pueblo.....	4,500	$55.00	$247,500
Golden Cycle, Colorado City.....	32,500	20.00	650,000
Portland, Colorado City.....	12,000	20.50	246,000
Portland, Colorado City.....	18,419	2.64	39,416
Portland, Independence	11,925	2.04	24,327
Caley-Jerry Johnson	450	4.00	1,800
	79,794	$15.15	$1,209,043

The Delmonico property, south-east from the Isabella, and west from the Victor mine, has been leased to Denver people for a long term of years. From the upper levels this property produced ore of good grade in the early days. At present the machinery is being overhauled. The Delmonico should be on the active producing list in the near future.

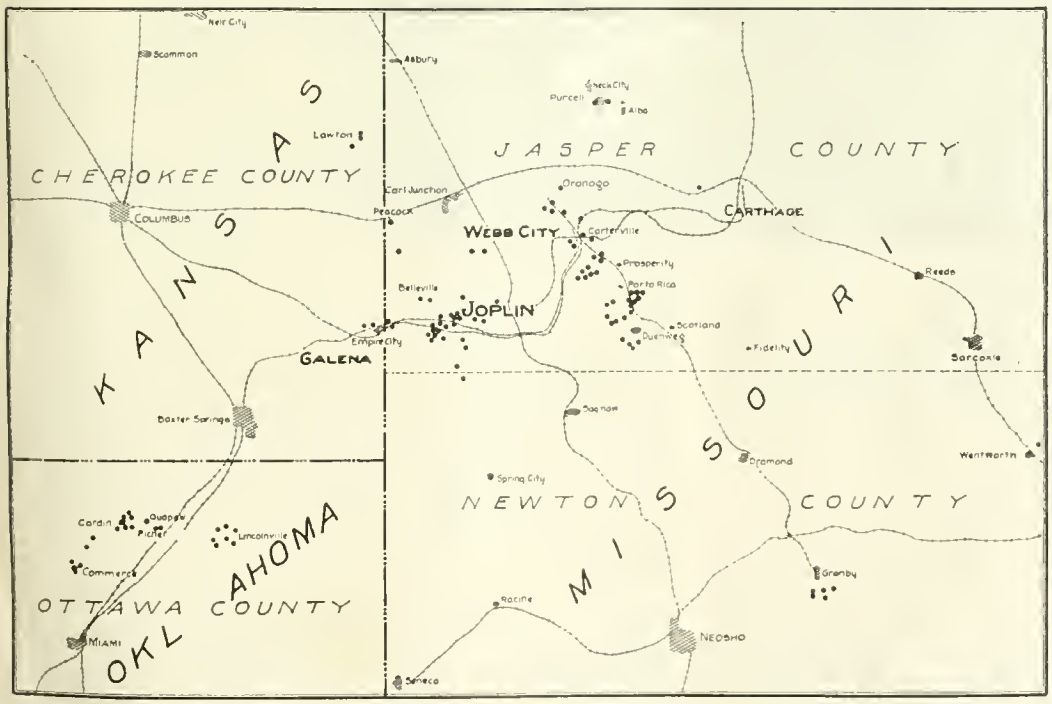
The quarterly report of H. McGarry, president of the El Paso Consolidated Gold Mining Co., shows that net earnings for the nine months beginning with April 1915 were $35,673. The indebtedness of the company during this period has been reduced to $2500. On January 1, 1916, there was $8454 in the treasury.

A strike of rich ore is reported from No. 15 level of the Lee shaft of the Isabella. In three rounds of driving the content increased from 12 to 800 oz. per ton. The stock immediately responded to the reported discovery, and sold at a higher price than for many months.

JOPLIN, MISSOURI

SHORT LAND & DEVELOPMENT CO. PLANS CONSTRUCTION OF NEW MILLS.—WORK STARTS ON ADMIRALTY COMPANY'S LAND IN MIAMI DISTRICT.

In addition to important development already under way, the Short Land & Development Co. contemplates the construction of several large concentrating plants. Recently the company undertook the re-opening of the Pocahontas mine, on a 10-acre lease of the Margaret Murphy land, at Thomas station, north of Joplin, and large 'turn-ins,' aggregating 180 tons per week, are now being recorded from this property, which for more than a year had been idle due to a fire that broke out in drift timbering. The shaft, at the time of the fire, had to be sealed to prevent spreading of the flames. Water rose in the mine, and the pumping problem became so serious that work was not resumed until the present company took charge several months ago. The name has now been changed to the Olive-Cherokee Mining Co., and an interesting feature of development is that present operations are in hard sheet-ground, at a depth of 200 ft., whereas previous work was all in very soft, timbering ground. A stratum, 100 ft. wide, 12 ft. high, and of undetermined length, is now being worked, and the recovery is from 9 to 10%. The mill has a capacity of 200 tons per shift of 10 hours.



THE MISSOURI-KANSAS-OKLAHOMA ZINC REGION, SHOWING, ACCORDING TO THE *Joplin Globe*, THE MILLS (BLACK DOTS) NOW WORKING WHICH WERE NOT IN EXISTENCE OR WERE IDLE A YEAR AGO.

On a 20-acre lease of the Madison Land & Leasing Co.'s property, immediately north of the Pocahontas, the Pennsylvania Lead & Zinc Co., one of the Short companies, has begun drilling and will drain the ground. It is planned to do 3000 ft. of drilling, and construct a 250-ton concentrating plant on the site of the old Powhattan mill, which was removed soon after operations were suspended there following the shutting-down of the Pocahontas. A lease developed by the Short company several months ago will soon have a mill. This is a 40-acre lease of the James Luke land, adjoining the H & F mine, a producing property, north-east of Joplin. Four drill-holes show ore from 186 to 205 ft. in very soft ground, although operations on all sides are conducted in hard ground. R. E.

Hollis and H. A. Moore of Louisville, Kentucky, and Kansas City people are associated with the Short company in this development. A shaft is into ore, and driving has started. Work on the new plant of 200-ton capacity is to begin within a month. The largest mill contemplated by the company will have a capacity of 350 tons a shift, and will be situated on a 40-acre lease of the James Lake land, west of Joplin. The lease lies south of the Muskingum mine, which is a big producer and north of the A. W. C. group of three mills, with a fourth now under course of construction near the proposed new plant of the Short company. Two shafts are into ore, the extent of which has been fairly well blocked out in 14 drill-holes. The company has appropriated $30,000 for development work and mill construction.

Foundations are in for two concentrating plants to be constructed by the Admiralty Zinc Co., five miles north-east of Miami, Oklahoma, in a district that only recently has sprung into prominence as a producing area. Mining will be conducted in a disseminated formation at a depth of 160 ft., although drilling has shown deeper ore. The mills will have a capacity of 250 tons each. They are situated near the Welsh Mining Co.'s plant, where new work is under way, and at which place a heavy flow of water is encountered below a depth of 180 ft. At the Welsh mine, pumps have been lifting 3500 gal. per minute for the past three months. Other new work in this district consists of plant construction at Picher, where two mills are now completed, a third is well under way, and a fourth has been started. The Blue Goose mine, some distance west of Picher is also a new property that is attracting attention because of the extreme richness of the ore now being milled. All these properties are on lands owned by Quapaw Indians, who usually receive 5% royalty.

The Warren Brewer Mining Co., on a lease of the Rex Mining & Smelting Co., in the east part of Joplin, has begun construction of a 100-ton concentrating plant on a lease that has been productive for some time. The poor custom-milling facilities in that part of the district necessitated the construction of the new plant. Drifts are heading into some good lead and zinc ore at a depth of 110 ft. Tarrant and Gill, also on the Rex land, are building a 50-ton plant to treat calamine that they are mining at a depth of 73 ft., and which they have been cleaning on hand-jigs. The new mill of the Little John Mining Co., on the Rex land, is nearing completion. It has a capacity of 150 tons.

D. D. Dewing has completed the construction of a 250-ton concentrating plant on a lease of the Zinc Corporation of Missouri property at Webb City, Missouri. Sheet-ore is mined from a depth of 220 ft. Two shafts will supply ore to the mill. Not far distant is the new plant of the National Lead & Zinc Co., now nearing completion.

AUSTIN, TEXAS

Difference of Opinion on the State Mining Laws.

Precious metal, oil, and all other mineral substances that have been found on land sold by the State of Texas since 1882 belong to the Government of the commonwealth, according to the official decision of J. T. Robinson, state land commissioner. A contrary view is held by B. F. Looney, attorney-general, who in a recent opinion stated that it is only on land that had been classed, prior to sale, by the State land department as mineral-bearing that the minerals are reserved to the State. In western Texas much of the former public domain was classed as grazing and agricultural, and on parts of these areas, valuable minerals and oil have been discovered. If Mr. Robinson's opinion holds good, the resources that are found upon privately-owned lands revert to the State. In order to determine the controverted question a test-case is to be made in the Courts. The attitude of Mr. Robinson as to the State's reservation of minerals on all lands that formerly belonged to the public domain has been adhered to for many years, and has caused the development of these resources to be greatly retarded. If Mr. Looney's interpretation of the law is upheld by the Courts, it will mean a large increase of mining and oil operations. It is stated that many men own land on which they have found minerals, but they do not care to make the fact public for the reason that the State would derive the benefit of the discovery, and the property would be open to filing by anybody.

ATLANTA, IDAHO

Revival of Mining and Milling in an Old District.

Mining and metallurgical operations in this part of Idaho (Elmore county) show considerably more activity than a year ago. There are some notable old producers in the district; a year ago they were practically all idle. As a result of the active policy started, principally by the Boise-Rochester Mining Co., a revival has set in, and new life has been infused into the little town of Atlanta, the centre of business. Mining conditions are favorable, excepting transportation facilities. For six months of the year heavy traffic with outside points is suspended on account of the roads over the mountains becoming impassable. During the other six months freight charges are excessively high. A year ago an effort was made to construct a road along the river valley communicating with Boise, the nearest supply base. This road would have been available for any kind of traffic the whole year, and sufficient money was raised from various sources for its construction. As a result of bad judgment in laying it out, portions were subsequently carried away by floods and the communities and mining companies most interested continue to suffer complete isolation for at least half of the year. Considering the known and prospective resources of this region that is a state of things which should be rectified in the near future.

The Boise-Rochester company, with headquarters at Boise, of which Leo J. Falk is president, is the principal operating company. It recently took over the property and 40-stamp mill formerly owned by the Bagdad-Chase Gold Mining Co. Work was started on the claims in the fall of 1915, and is being advanced on an increasing scale as the winter advances. A Bleichert aerial tram, capable of carrying 120 tons in eight hours, now connects the lower workings of the mine with the mill. Recent development in the mine has opened a considerable quantity of ore worth from $10 to $20 per ton. At the present time 20 stamps are dropping continuously on this grade of ore. Under the former owner's management the method of extracting ore was by the caving system, but this proved unsuitable under the conditions prevailing, resulting in an excessive quantity of waste being mixed with the ore sent to the mill. The vein material is exceedingly soft and friable, and the country rock swells whenever it is left exposed. These conditions necessitate heavy timbering and continued working of the ground, and it was probably to avoid expenditure under these heads that the former system was adopted.

Another obstacle to successful operations heretofore was the difficulty of treatment. Amalgamation was followed by fine grinding, and an elaborate system of classification and concentration extracted a fairly high percentage of the bullion, but trouble was experienced in handling the concentrate. Transport charges preclude the shipment of anything but very high-grade product, and local treatment by roasting followed by cyanidation was only partly successful. An auxiliary plant has now been installed, and is ready to commence operations. In it the concentrate will be ground fine in tube-mills, agitated with cyanide solution in a Pachuca tank, and the gold precipitated from solution by zinc-dust. It is confidently anticipated that this treatment will be a complete commercial success, in which case it is intended to re-model the main plant with a vein treatment of the whole ore by a similar process. R. H. Richardson is superintendent.

The property of the Monarch Gold Mining Co., adjoining the Boise-Rochester on the west, is under lease. The lessees have been engaged during the late summer and fall treating the dump ore by fine grinding in Huntington mills, amalgamation, and concentration. A recent clean-up is reported to be satisfactory.

The Overlook Gold Mining Co. at Black Warrior, some 14 miles from Atlanta, is busy. Ten additional stamps were sent in while the roads were still open, and these are in course of erection. An aerial tram has also been erected. Mr. Work is superintendent.

LEADVILLE, COLORADO

RESULTS OF DREDGING IN THIS DISTRICT

The Derry Ranch Gold Dredging Co. has under lease 2000 acres of ground, known as the Derry ranch, which is situated 12 miles south of Leadville and in the Arkansas valley, at an altitude of about 10,000 ft. The ground was originally drilled by W. H. Radford, and about 150 acres has been proved to contain profitable gravel, and subsequent dredging is indicating that these estimated values are being exceeded by about 50%. The dredge has operated just two months and handled a total of 143,000 yards. However, the first 15,000 yards consisted of clay, with no gold, thereby reducing the actual gravel yardage to 128,000, from which was extracted $69,291. Operating costs for this period amounted to $6953, which is less than 5c. per yard for all the yardage handled. This working cost is claimed to be as low as any boat of the same size, especially when one considers that the local cost of electric power is rather high, 1.65c. per kw-hour. The ground is also difficult, containing many large boulders.

DREDGING NEAR LEADVILLE, COLORADO.

One thing that tended to keep the working cost down was the small amount of power consumed and it is interesting to note that the dredge only required on an average a total of about 155 hp., whereas formerly this dredge, when operating in Montana, required over 250 hp. The saving was caused by the re-modeling and re-designing, and the many changes made by the New York Engineering Co. with a view to reducing the power consumption and securing large yardage.

The dredge was shut-down on January 10, on account of the severe climatic conditions, which would have increased operating expenses unduly, and rather than do this, it was decided to wait until spring. The total cost for building the new hull and reconstructing the entire dredge was just about $100,000, so that with one more month's operation, this amount of money will be won back, and the rest will be all velvet.

The good work done by this dredge is due largely to the efforts of Robert F. Lafferty, vice-president and general manager, who was formerly an Oroville dredge operator, and whose experience has stood him well in the management of this enterprise. A. C. Ludlum is the president and principal owner of the Derry Ranch Gold Dredging Co., as well as the sole owner of the New York Engineering Company.

After several months' shut-down the Castle View mine on Carbonate hill is being re-worked. A large quantity of 22% zinc carbonate is available, but a peculiar market made it difficult to secure a contract. This has been arranged, and the output is 50 tons per day.

ATOLIA, CALIFORNIA

LATEST FROM THE TUNGSTEN REGION

Notwithstanding the fire which destroyed the new mill of the Atolia Mining Co. on January 25, causing a temporary suspension of nearly all mining operations by that company, work has been resumed, and the old Huntington mill is again crushing night and day. There has been a resumption of work in the mines, relieving the situation. Already the frame-work, super-structure, and roof-timbers are in position for another and much better mill than the one destroyed.

Production of scheelite is increasing from lessees and operators of claims that adjoin the Atolia company's property. Most of this product is derived from placer ground. A number of discoveries of scheelite in quartz are reported from the west slope of the Rand mountains. On the road between Atolia and Randsburg, the main gulch is cut-up by placer workers with every manner of contrivance, both wet and dry.

for saving the gold, tungsten, and black-sand concentrates.

There are ten ore-buyers here who take ore from 2% WO_3 up. The ruling prices are $2 to $2.50 per pound cash on the ground, or about double that if money is not available until returns come from shipments outside. High-grading continues, as detection and conviction are difficult.

WASHINGTON, D. C.

PROGRESS OF THE MINING LAW BILL.

Legislation in Congress on the codification of the mining laws has simmered down to the point that it is to be done, not by a commission, as mining men had hoped and proposed, but by a sub-committee of the committee on mines and mining of the House of Representatives. Action to that effect has been taken by the committee, which, at a recent meeting by the close vote of seven to six, decided not to report out any of the bills before the committee on the codification. The bills were those of Representative Taylor of Colorado and that of Senator Smoot of Utah, which latter had come to the House on being passed by the Senate, where there had been no opposition whatever. The committee at the same time voted to have the revision and codification done in the committee itself, by a sub-committee composed of its own members.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Chichagof

The Chichagof Mining Co. is installing a flotation plant in its 20-stamp mill and concentrator.

Cordova

According to George W. Silas of Boston, the Valdez Creek Placer Mines Co. will spend $125,000 this year for supplies and equipment. This includes 139 tons of Bouery steel riffles for 1400 ft., 1000 ft. of 15-in. and 1000 ft. of 18-in. pipe and fittings, derrick and boom with hoist and motor, and three No. 6 double-jointed, ball-bearing giants with nozzles and deflectors. Supplies already purchased at Seattle are on their way to the property. The new equipment should be erected by May 20, when there will be plenty of water for sluicing. Two Pelton wheels will drive a generator for power, saw-mill, etc., while an Ingersoll-Rand compresser will supply air for nine jackhamers. A Keystone drill is used for prospecting. The company's property covers 5000 acres. It will be an important producer this season. The new Government railroad will go through Broad Pass, 30 miles from Valdez creek. The ditch for water-supply is 6200 ft. long, 8 ft. wide at the bottom, 15 ft. at the top, and 3 ft. deep. The main pipe is 4000 ft. long, with a 5-ft. intake, and branches 1000 ft. long. In the season of 100 days a profit of between $200,000 and $300,000 is expected from $1 gravel. Pierre Bouery, for 15 years at the Lagrange mine, California, is manager.

In connection with the supplies mentioned above, it may be stated that they are paid for, the freight paid for, and 40 horses, 6 bob-sleds, and 20 men are almost at the property with about 450 tons of freight.

Fairbanks

If the work proposed, and that being started on Goldstream, is continued, that area will be very busy next season, there being more plants than during last year.

Juneau

Juneau has been suffering from storms and cold weather, but little damage is reported.

December returns of the mines on Douglas island are as follows:

Operations.	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Stamps dropping	120	540	300
Ore crushed, tons	19,425	80,693	28,510
Gold yield	$29,750	$141,866	$91,881
Average per ton	1.53	1.76	1.90
Expenses	25,931	99,112	70,666
Construction	10,728	10,476	24,316
Profit	.....	$30,859	.....
Loss	$7,207	.....	$4,014

A certain amount of development was done by the companies for one another in accordance with the general scheme of operations.

The owner of the Jersey City claim, M. J. O'Connor, states that his property, under option to the Alaska Treadwell two years ago, is almost bonded to an Eastern syndicate.

In the suit of certain bondholders of the Alaska-Ebner Gold Mines Co. v. the United States Smelting, Refining & Mining Exploration Co. and others, Judge J. M. Mayer in the Federal District Court of New York decided that the deposit agreements made on June 30 and December 30, 1913, complained of as usurious, are void. Certain shares of the bondholders' committee are subject to a lien of defendants of $170,072, but the latter must not sell them until given permission by the Court.

ARIZONA

Cochise County

During 1915 the Copper Queen properties produced about 774,000 tons of ore, yielding 83,000,000 lb. copper, exclusive of lessees' and other supplies. Development amounted to 70,013 ft. There has been an increase in the sulphide content of the ores, resulting in changes at the smelter. Pyrite smelting tests are under way. Churn-drilling on Sacramento hill added considerably to the oxidized reserves; more is to be done. Increased efficiency underground is reported by the use of different rounds in different ground, better stemming, and water-drills. Steel-sharpening charges were reduced in the central plant. At the Sacramento shaft 350 ft. of concreting was accomplished from October 1 to December 31. Fifteen sets of lessees are at work. Larger fans greatly improved ventilation. The safety-first department is satisfied with the year's accident results.

From the Shattuck the daily output is 450 tons of copper ore, and 100 tons of lead ore; these go to Douglas and El Paso respectively. Development generally is very satisfactory. At 200 ft. depth is high-grade silver-lead ore; at 300 ft. rich copper glance; and at 600 ft., 2% vanadium and some lead ore.

Gila County

During 1915 the Globe-Miami district's production of copper was approximately as follows, in pounds:

Miami	42,000,000
Old Dominion	27,731,272
Inspiration	22,000,000
Arizona Commercial	3,500,000
Iron Cap	1,436,000
Warrior	3,800,000
Gibson	1,200,000
Superior & Boston	550,000
Other sources	200,000
Total	102,417,272

All these mines had busy periods with splendid results. The new Inspiration mill gradually came into commission, while the International smelter was completed late in May. It produced 51,718,845 lb. of copper, 31,912,916 lb. from the Miami, 18,783,450 lb. from the Inspiration, the remainder from custom ores. The district is expected to make a much larger output in 1916, largely from the completed Inspiration mill and the many lessees and small syndicates extracting ore.

Greenlee County

In discussing the late strike, *The Copper Era* of Clifton makes the following remarks:

"After a loss of approximately $2,000,000 in wages to the employees, to say nothing of the heavy losses sustained by the mining companies, the unauthorized strike in this district called by Guy E. Miller, organizer of the Western Federation of Miners, is at an end. By an almost unanimous vote of the

men involved, a decision was reached on January 24 to return to work on the proposition submitted by the mine managers on the 8th through Henry Hill and R. R. Webster of Clifton, who for the past two weeks have been acting as mediators. In their efforts to secure an acceptance by the men of the proposition the mediators have received the assistance of the Sheriff, local labor leaders, and the Federal investigators, and to all of those who assisted in bringing about the termination of the deplorable conditions, which have existed in this district for the past four months, the thanks of the community at large is due. Lack of financial support from labor organizations throughout the country played an important part in the termination of the strike. It became known towards the end of the struggle that Guy Miller never was authorized to start a strike in this district. In this particular the strike was illegal, and was not recognized as entitled to support through assessments, although the strikers received liberal contributions from various parts of Arizona, notably from Miami. The strike is over and everybody is happy. The *Era* believes in letting the dead bury its dead. This is not a time for recriminations on either side, and we believe good for all concerned will be the outgrowth of the disturbed conditions through which we have just passed, and that we are now entering upon an era of better feeling and general prosperity than ever known before in the Clifton-Morenci district."

Mohave County

After two years' idleness the Frisco Gold Mines, 24 miles west of Kingman, in the Union Pass district, has resumed work in charge of S. Brethour. A 50-ton mill was previously operated. Finances were the cause of shutting-down.

At a depth of 665 ft. in the United Eastern the cross-cut has opened the vein, where it is of high value.

The following remarks were made by J. K. Turner of Goldfield, Nevada, concerning the Oatman region:

"The district is vastly greater than Goldfield, where all the area of attractive production was included within 250 acres. In the Tom Reed-Gold Road district there is a margin of two miles from the Times group, where ore was recently encountered, to a point west of the Tom Reed, where all development is encouraging. There are more than a dozen properties in the district which should make good, in addition to those that have already been mentioned. Their success is based, of course, on efficient management and continued development. Along the central or main vein it probably will be necessary to go to a depth of from 400 to 500 ft., but there has been more erosion in the southern section, and here the gold may be expected much nearer the surface."

The Tom Reed-United Eastern merger has fallen through.

The Chloride district is considered, by people who have recently been there, to be worthy of the interest of capital. Some good mines are already large producers.

CALIFORNIA

Amador County

It is definitely announced that the old Eureka mine at Sutter Creek has been sold by Mrs. Hettie Green to a strong group of mining men. The transfer was made formally in San Francisco on February 7. The consummation of this important business is due to the initiative and energy of T. Walter Beam, of Denver, who has been working on it since 1912. The new management consists of Mr. Beam as president and general manager, J. B. Mackie as vice-president, and Frank Swed as secretary. The board of directors includes the three foregoing, together with J. C. Gorrie and John B. Farish. Mr. Beam is proceeding to Sutter Creek to commence the work of rehabilitation and equipment. A suitable plant will be erected at once, including new shaft-house and hoisting-engine, mill, and tramway. In regard to the sale-price, the actual figure is not known, but it is over $500,000. The deal has created a great deal of interest, for it indicates the confidence shown in the productiveness of this part of the Mother Lode.

Calaveras County

(Special Correspondence.)—The Royal Gold Mines Co., operating the Royal mines, is now treating 140 tons of ore daily, and employs 100 men. The managing director, F. N. Page, is now planning to make important changes. Twenty of the present 50 stamps will be taken out, and re-grinding machines for fine grinding used in their place. Oil flotation will take the place of present tables and vanners. It is also expected that some process—cyanidation or chlorination—will treat the concentrate on the ground, and avoid the present shipment to smelters.

Hodson, February 1.

The new 350-ton mill of the Calaveras Copper Co. is expected to be ready within 60 days. Flotation will be part of the process. According to F. W. Royer ore reserves available at once amount to 149,220 tons, averaging 3% copper, also 151,200 tons of a lower grade; this is down to No. 6 level. Some good ore is said to have been opened on No. 10 level. Crude ore and concentrate was shipped during 1915, paying for many expenses. The finances are now being re-arranged.

Eldorado County

A nugget worth $590 was found last week in the well-known Jones pocket-mine, five miles south of Placerville. A good deal of development has been done, and a two-stamp mill is kept busy.

Sierra County

(Special Correspondence.)—The vein on the 200-ft. level of the Monarch Con. has been opened for over 300 ft. by the west drift. It averages seven feet in width and is of milling grade. The shaft is to be deepened to 400 ft., and a main working adit will be driven later. Twenty stamps are dropping, with most of the ore coming from the 200-ft. level. A rock-crusher and other machinery is being installed. Forty men are on the pay-roll. Tailing is being stored in a recently constructed pond for future treatment. At the Cleveland mine, controlled by the same people, shaft-sinking has reached 350 ft., and is progressing rapidly. The 10-stamp mill is working one shift. An Ingersoll-Rand compressor is being installed to facilitate more rapid shaft work. Twenty-five men are employed. Dan McGonigal is manager of both mines.

Ore averaging $10 per ton is going through the Keystone mill, which is running one shift per day; 10 stamps are dropping. Mine developments continue to open fair-grade ore. The property is operated on a lease by Bigelow and Gilbreath.

Snow-slides have caused some damage in this district, but many of the reports recently published have been grossly exaggerated. The Phoenix mill has not been damaged, although recent reports were to the effect that the plant had been swept into the canyon. Repairs to the Sierra Butte mill will be made as soon as weather conditions allow.

Sierra City, February 7.

Siskiyou County

Yreka people expect that the coming season will be a busy one for this county, as many engineers have been examining properties. The copper mines on the Klamath river and Clear creek will continue their work. On Greenhorn creek the El Oro Dredging Co. moved 994,742 cu. yd. in 16 months. The ground is somewhat difficult to dig.

Trinity County

A long adit, to open the orebody at a vertical depth of 900 ft., has been started at the Golden Jubilee, near Carrville. A large treatment-plant is to be erected. Other properties in this and the Trinity Center district are preparing to resume work in the spring.

COLORADO

Clear Creek County

(Special Correspondence.)—The property of the Dorie Trust (Ltd.) of London, situated on Saxon mountain, just below the depot at Georgetown, will pass to the Ruler Mining Co. on April 1; negotiations for transfer are nearly complete. The Dorie adit has been driven 3009 ft., and it is proposed to extend it to intersect at depth the mines in what is known as the Highland Park section.

Six inches of ore containing 18 oz. gold per ton has been opened for a length of 35 ft. in the Crockett vein, just above Idaho Springs. A shipment of 15 tons was made last week.

The Argo mill has resumed work after a 10 days' shut-down to permit installing a flotation annex. It is reported that a high recovery is being made on the by-products, consisting of silver, zinc, and copper. J. A. Pearce is superintendent.

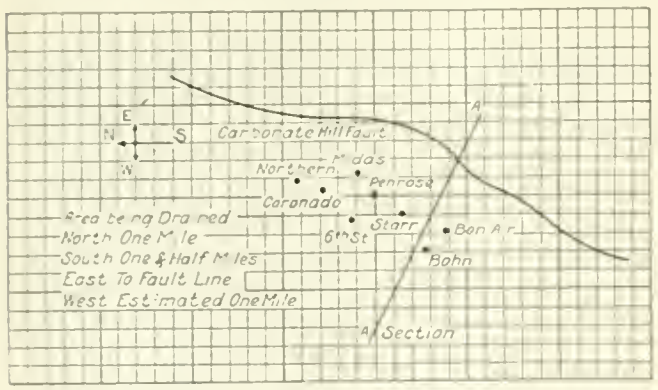
Large shipments are being made from the Comstock mine on Seaton mountain to the Combination mill. The product is low grade.

Idaho Springs, January 24.

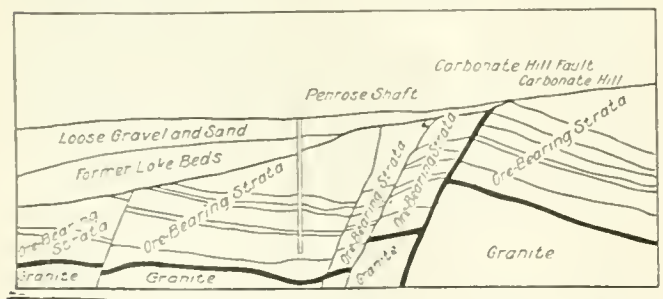
Lake County (Leadville)

Higher prices for silver have stimulated ore extraction at several properties.

The Penrose shaft pumps gained eight feet last week. At 750 ft. a drift connects the shaft with the Star workings, which hold a large quantity of water. In the *General Electric Review* for February, W. H. Horton, Jr., describes the un-



SKETCH OF THE DRAINAGE-AREA OF THE DOWN TOWN DISTRICT, SHOWING THE RELATIVE POSITION OF THE VARIOUS SHAFTS LOCATED THEREIN.



CROSS-SECTION OF THE DRAINAGE-AREA OF THE DOWN TOWN DISTRICT.

watering of the Down Town district in an interesting and well-illustrated article, from which the accompanying plans are taken. Considerable space is given to notes on the pumps and motors, especially comparing the cost of operation with the old steam-plant, and the modern motor-driven centrifugal pumps, showing a marked decrease in cost of installation and operation.

Owing to what is suspected to be 'surges' in the power supply to the Penrose shaft pump motors, the coils of the machines are burning out occasionally, resulting in delays.

Prospecting for manganese ores is under way on Carbonate and Breece hills.

The Anderson adit is in 1300 ft. in Prospect mountain in hard rock, a mixture of white porphyry and quartz.

The First National mine in Iowa gulch, where good bodies of lead-silver ore and zinc carbonate are said to exist, is being unwatered.

The Fortune mine in Evans gulch is sending gold-silver-copper ore to the Salida smelter; this comes through the Yak tunnel. Zinc carbonate has been developed also.

From the Gordon-Tiger mine at Twin Lakes to its 100-ton mill a new tramway has been constructed.

Ouray County

During December the Camp Bird mine produced 2468 tons of ore with a profit of $43,000.

IDAHO

Shoshone County (Coeur d'Alene)

The following announcement has been posted at Kellogg:

"To all employees of the Bunker Hill & Sullivan Mining & Concentrating Co., Caledonia Mining Co., Sierra Nevada Consolidated Mining Co., and Ontario Mining Co.: Hereafter when lead is 5c. per lb., or higher, a profit-sharing bonus will be paid in addition to the regular or minimum scale of wages, as follows: 25c. per shift when lead is 5c. per lb. and under 5.5c. per lb., 50c. per shift when lead is 5.5c. per lb. and under 6c. per lb., 75c. per shift when lead is 6c. per lb. and over. The price of lead applying to be the average New York price for the preceding month. During January, 1916, the average New York price of lead was 5.84c. per lb. and accordingly for February, 1916, a bonus of 50c. per shift will be paid all employees, and subsequent months in the same manner. When the average price of lead at New York is less than 5c. per lb. no bonus will be paid, and the regular scale applied."

Development at the Hypotheck has been so good that a mill is contemplated. At 1100 ft. depth a two-foot shoot assays 80% lead.

During December the Caledonia mine produced 497 tons of shipping ore and 961 tons of concentrate, valued at $125,482, the latter product from 3764 tons of ore. This yielded a profit of $79,973. In 1915 the company's output was 15,004 tons of ore containing 11,141,000 lb. lead, 1,212,730 oz. silver, and 659,660 lb. copper, worth $1,246,860. The profit from this was $760,324. According to the manager, Charles McKinnis, there is enough ore developed to operate for three years at the present capacity. Sixty-five men are employed. A car, 39 tons, of ore on January 7, gave $6832 net.

The town of Wallace is to pave certain streets at a cost of $120,000.

MICHIGAN

The Copper Country

The first of five shafts is being sunk at the White Pine Extension. Some of the machinery has arrived. At 200 ft. a short cross-cut will be driven to the lode, which will then be opened. Some drilling is being done, two miles from this shaft. Diamond-drilling is nearly complete on the property. A number of buildings have been erected. In the spring a 100-ton mill may be built.

The Isle Royale three-stamp mill is crushing up to 2200 tons of ore daily, the largest recorded. An interest has been acquired in the Point Mills plant, so that the daily output can be increased to 3000 tons.

All of the Champion tailing is to be re-ground, and more Wilfley tables installed. Manganese-steel balls are used in the Hardinge mills. The Baltic and Trimountain tables will be added to later on. A turbo-generator, taking exhaust steam from the Champion stamps, will drive all the re-grinding plants of the Copper Range companies.

The ore railroads are preparing for a busy summer, and

new cars and equipment are being made for the Mineral Range, Copper Range, Calumet & Hecla, and other lines.

Improvements to the Mohawk and Wolverine mill at Gay will not be started until spring. The Wolverine produced 7,194,015 lb. copper in 1915, a fair increase. The average yield was 17.79 lb. per ton.

The Champion company has declared $2 per share, making $5 for the current year.

MISSOURI

Jasper County

What is thought to be a record zinc-content in concentrate is reported from the 1915 company's Missouri Standard mine at Klondike, a carload recently assaying 64.70% metal. Pure blende contains 66.66% zinc. This company also had a record settlement for concentrate at $139.90 per ton.

The Granby district is mainly a calamine producer, but the Golden Rule company recently sold 700 tons of blende at a base price of $105 per ton, the largest sale, in value, for that district.

The National Lead & Zinc Co. is increasing its output from the Googie and Lucky Tom mines; its new mill is nearly complete.

Twenty-five tons of high-grade concentrate daily is the Bradley Lead & Zinc Co.'s output from the A. B. C. ground at Chitwood. At its Lincolnville property another mill will soon be working.

Owing to a fire that destroyed the bag-house of the Galena smelter, an old smelter at Webb City has been re-started. The Picher Lead Co. owns both plants, also a large one at Joplin. The Galena plant will be repaired.

MONTANA

Granite County

After being idle for many years, the Montana-Frisco mine at Tower is to be unwatered. Prospects are considered good.

Jefferson County

The Boston & Corbin company has resumed work at its Bertha mine, one mile from Corbin. Previous work was unprofitable with low copper prices, and the mill did not recover a high percentage. The mine has to be unwatered first.

Lincoln County

The Snowstorm Mining Co. of Idaho has acquired the Banner and Bangle lead-zinc mine near Troy, from the Greenough estate. Leo Greenough is manager of the Snowstorm. The 250-ton copper mill at Larson, Idaho, will be moved to Troy in March. Few changes will be required in treating the new ore. The Banner and Bangle is already employing 200 men.

Silverbow County

Owing to ore freezing in storage-bins at Butte mines, blasting had to be resorted to last week.

After completing work between 1700 and 1900 ft., work has been resumed at 1400, 1500, and 1700 ft. in the Davis-Daly. A new hoist, costing $50,000, has been ordered. The company has $5000 cash at Butte, and $20,000 due on ores sent to the smelter.

Butte & Superior is employing 1850 men, the pay-roll in January being $240,000.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated company for January is as follows:

Ore mined, tons	31,000
Gross extraction	$209,000
Operating expenses	149,000
Net realization	60,000

Stoping at 1580 ft. in the Atlanta shows considerable improvement and 4½ ft. of ore now assays $158 per ton, mostly in copper, so that it must be sent to the smelter.

Copper produced by the Jumbo Extension in 1915 amounted to 1,259,388 lb., from 22,562 tons of ore, which also contained 30,480 oz. gold and 99,459 oz. silver. The mine is in fine condition, yielding 100 tons daily.

Humboldt County

At the St. Anthony tungsten mill at Toy, 18 miles southwest of Lovelock, new rolls have been installed. The daily output is 50 tons of ore. A wide vein is being opened down to 100 ft. depth, averaging 4% WO_3. Fifty-five men are employed in the mine, mill, and transport.

Owing to deep snow the Nevada Packard company is having difficulty in hauling its bullion between the mill and the Nevada Short Line, a distance of four miles occupying seven hours. The town of Packard, about ¾-mile from the mine and mill, and inhabited exclusively by employees of the company, is the only mining camp in Nevada that has no saloon. Neither are there dance-halls or other places of ill-repute. Gambling is not tolerated. The town has a population of almost 100 men, women, and children. It is electric lighted, and has water from the mountains piped to each house. It is the intention of the company to build a club-house for its employees. It will be placed under the immediate control of the men, and the profits will be divided among them in ratio to the length of service. During the recent storms Packard was isolated for about two weeks, and fuel was brought in with much difficulty from Lovelock, just as the last had been consumed.

Mineral County

Renewed activity is reported from the quicksilver deposits east of Mina. A furnace has been ordered for the Pepper and Keough mine, and one is contemplated for the Red Devil.

Nye County

Eight mines at Tonopah last week produced a total of 8445 tons of ore worth $177,270.——Raise No. 5 above 800 ft. in the Belmont is up 106 ft. in 4 ft. of rich ore; this is considered of importance. Work generally on this level is highly satisfactory.——None of the other mines have anything new to chronicle, save that development continues as good as desired. ——Lessees at the Montana are extracting good ore for the West End mill.

White Pine County

In its statement to the county assessor, the Nevada Consolidated announced that during the last quarter of 1915 it mined 831,944 tons of ore yielding $3,904,890. This gave $1,837,022 net, on which the tax was $26,271. The Giroux, whose ore is treated by the Nevada Con., mined 22,027 tons, for a profit of $23,158. The tax was $3312.

The Aurum district promises to have an active season when the snow clears; many minerals occur there.

NEW MEXICO

Santa Fe County

During seven months ended December 31, 1915, the Santa Fe Gold & Copper Mining Co. produced 3,376,246 lb. matte, assaying 51.75% copper, containing 2104 oz. gold, and 24,570 oz. silver. The profit was $141,430, against a loss of $279,592 in 1914.

OKLAHOMA

Ottawa County

Near Commerce the Acme Mining & Development Co., controlled by W. S. Pate of Joplin, has leases on 2000 acres of land, which is to be drilled and sub-leased. The Luella and Henderson lead and zinc companies, under the same control, are to drill, and the former will erect a mill.

UTAH

Beaver County

(Special Correspondence.) The Beaver Goldzone Mining Co reports that it is negotiating with Los Angeles people for a sale of its property.

At the Whalen lease the Davis lease vein has been cut in an adit at 60 ft. depth. There is six feet of quartz and one foot of manganese, and 30 ft. of formation.

Owners of the Nevada Wonder and Golconda Extension claims have sold an interest to J. M. Murdock of Beaver. Development has been resumed at the latter property.

The Davis lease, the original rich discovery at Fortuna, is to be developed with greater speed from now on in both the upper and lower levels. The U. S. Smelting company has secured the right to work and mine the ores below the 125 ft. level of the Davis lease shaft, providing it will permit the use of its own shaft as an exit for the lease ores between the 50 and 125-ft. levels.

Fortuna operators and promoters, G. A. Kernick, E. D. Dart, and C. W. Whalen, figure in a recent transaction in the western part of this county. They have agreed to take over the White Pine copper-silver-lead property adjoining the St. Mary mine in the Star district, near Milford, on a bond for $25,000. Ore of good shipping grade is exposed in three places in an adit and winze, and the new operators have already put men at work developing these orebodies and extracting ore.

At the Copper Granite mine, five miles west of Fortuna, the lessee has cut four feet of good silver-lead ore.

Six companies are busy near the Sheep Rock mine, five miles east of Fortuna.

Surface veins at the Magnolia are five feet wide, and assay from $11.37 to $30 per ton in gold and silver. A shaft is being sunk on ore.

Fortuna, January 26.

At the Whalen lease on the Davis vein a six-foot shoot of rich ore has been opened at 60 ft. depth. This is the fourth shoot opened in this vein. It occurs at a junction.

Juab County

Only 76 cars of ore were shipped from Tintic last week, due to snow-storms.

Summit County

During January Park City mines shipped 7370 tons of ore.

KOREA

The Seoul Mining Co., operating the Suan concession in Whanghai province, Chosen, reports the following results for January:

Ore treated, tons	16,745
Mill operating, days	28
Recovered:	
Bullion	$ 83,250
Concentrate	77,809
Total	$161,059
Expenses	50,000
Operating profit	$111,059

Copper is calculated at 12c. per pound.

The U. S. Civil Service Commission, Washington, D. C., announces an open competitive examination for chief of editorial division. From the register of eligibles resulting from this examination, certifications will be made to fill a vacancy in this position in the Bureau of Foreign and Domestic Commerce, Department of Commerce, at Washington, at a salary of $2500 per year, and vacancies as they may occur in positions requiring similar qualifications. Applications must be in by March 7.

PERSONAL

H. R. Bostwick is at Denver.

W. Motherwell is at Victor, Colorado.

Chester A. Fulton is examining mines in Cuba.

W. H. Landers is examining quicksilver mines in Oregon.

John W. Finch is ill with typhoid in a New York hospital.

E. J. Howard Wright has returned from London to Bolivia.

V. H. Hughes has returned to Tulsa, Oklahoma, from a trip to Tampico, Mexico.

T. Walter Beam has gone to Sutter Creek as manager of the old Eureka mine.

C. H. James has opened offices in Kingman, Mohave county, Arizona, for general consulting practice.

Alex. J. M. Ross has been appointed general mine foreman for the Homestake Mining Co., South Dakota.

H. G. Reynolds, chemist with the Old Dominion company at Globe, Arizona, has accepted a position in Siberia.

Arthur R. Weigal has been at Anaconda, Butte, and Salt Lake City. He is expected shortly in San Francisco.

Louis Webb succeeds Pierre Bourry as superintendent of the Lagrange hydraulic mine, Trinity county, California, the latter going to the Valdez Creek mines in Alaska.

Arthur C. Cole, recently superintendent of the Cananea Consolidated Copper Co.'s smelter, Sonora, Mexico, has been appointed manager of the R. M. Stone Mines Co., Phoenix, Arizona.

H. H. Stoek, head of the department of mining engineering of the University of Illinois, has been appointed by Governor Dunne as a member of the State Mining Investigation Commission.

William Gallagher, formerly mechanical engineer with the Cleveland-Cliffs Iron Co. at Ishpeming, Mich., is now in charge of the mechanical and electrical work of the Mohawk and Wolverine mines, at Calumet.

Frank H. Probert is to lecture to mining students at the University of California on February 21, 23, 24, and 25, at 4 p.m. each day. The subject will be 'Outcrops and the Zone of Oxidation.' Lecture 1 will discuss the Anatomy of the Earth's Crust. Physical Forces at Work. No. 2. Life History of the Outcrop. Contributory Causes to the Constant Change. No. 3. Chemical Forces at Work. Migration of the Metals. No. 4. Significance of Surface Signs. Types. These lectures are open to the public.

W. H. Rigg lost his life when the *Persia* was sunk in the Mediterranean; he was on his way to Burma.

Schools and Societies

The eighteenth annual meeting of the Canadian Mining Institute will be held at Ottawa on March 1, 2, and 3. Application is to be made for a royal charter. A. A. Cole is nominated for president. Nineteen papers, including four on flotation, are to be read. Visits will be made to the Mint, ore-dressing laboratories, etc.

The United Engineering Society of New York has issued the annual report of the Library Board for 1915. The revenue was $17,445, and expenditure $16,380. There were 12,820 visitors. Periodicals received totaled 17,591. The equipment was increased, and gifts were received. Some interesting library notes are given.

The committee of management of the International Engineering Congress, 1915, announces that the volume on 'Mechanical Engineering' is ready for distribution, and members who have subscribed to this volume will soon receive it. The other volumes will be issued as quickly as possible. W. A. Cattell is secretary, at 425 Foxcroft building, San Francisco.

THE METAL MARKET

METAL PRICES

San Francisco, February 9.

Antimony	44
Electrolytic copper	27.75
Molybdenum: dull, 90% MoS_2, per pound	$1.40
Pig lead	6.50—7.45
Platinum; soft metal, per ounce	$85
Platinum: hard metal (containing iridium), per ounce	$89
Quicksilver: per flask	$290—300
Spelter	21
Tin	43
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, February 9.

Antimony: stronger, 50% product, per unit	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	15—18
Magnesite: crude, per ton, f.o.b.	7.50—10
Magnesite: plastic, no iron and lime, calcined, per ton	50
Magnesite; refractory, up to 7% iron, calcined, per ton	30—40
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	40—50

So many operators of chrome, tungsten, molybdenum, and other properties write to use asking where they may dispose of their ores that we call attention to the 'Buyers' Guide' on the last page of each issue. Under 'Metal Buyers and Dealers' are listed the firms with which we recommend that mine operators open negotiations. These dealers buy, or will refer you to buyers, of practically all ores at present in increasing demand.

EASTERN METAL MARKET

(By wire from New York.)

February 10.—There is a strong upward move in copper, prompt metal is scarce; lead is likely to become scarce; zinc is strong.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Feb.	3	Dec. 29	54.05
"	4	Jan. 5	55.67
"	5	" 12	56.62
"	6 Sunday	" 19	56.68
"	7	" 26	57.14
"	8	Feb. 2	57.02
"	9	" 9	56.79

June	56.43	49.03	....	Dec.	49.27	55.34	....

Business has been less active in London, but the Mint and Continent have bought steadily. There have been Indian bear sales. America is rather a hesitant seller. There is about 5,500,000 oz. in London. The general undertone is good.

On February 5, silver worth $567,483 left San Francisco for China. Last week the Nipissing, Ontario, sent 157,607 oz. to London.

Pixley and Abell have issued their annual chart, covering 83 years, showing the important phases of the silver market.

COPPER

Prices of electrolytic in New York, in cents per pound.

Owing to bad weather the Michigan output in January was only about 75% of normal. Anaconda produced 23,200,000 lb. in January, a decrease of 2,400,000 lb. Old Dominion yielded 3,095,000 pounds.

December outputs were 6,302,045 lb. from Chino, 6,201,247 lb. from Nevada Con., 6,912,360 lb. from Ray, 14,497,485 lb. from Utah, 3,900,000 lb. from Miami, and 4,000,000 lb. from Cananea.

Phelps, Dodge & Co.'s mines produced 139,432,879 lb. in 1915, a decrease of 700,000 lb., accounted for by trouble at the Detroit and Moctezuma mines. The Copper Queen's increase was 10,000,000 pounds.

Formerly the American Brass Co. consumed 100,000,000 lb. copper in 12 months; now it uses this quantity in two months.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

The quicksilver market is rather quiet, though steady. The product of many outlying mines is held up on account of bad weather.

Imports into England last year were 40,579 flasks, an increase of 3011; exports were 13,020, a decrease of 9955 flasks.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Tin is steady at 41.25 cents.

Eastern Metal Market

New York, February 4.

Copper is at present held at 26 to 27c., producers are sold up for months to come; and it seems probable that 30c. may yet be reached, despite the fact that a part of the trade deplores what really are famine prices. Foreign stocks are diminishing, and the demand from abroad is heavy. Zinc has had a quiet, uneventful week, but after an easier trend in prices, is taking on more strength in sympathy with copper. The lead market is strong, largely because of the heavy demand from abroad. Tin is easier in price, and the large deliveries into consumption indicate the extent to which consumers bought for their future needs. Antimony is scarce and firm at higher levels. Aluminum has continued quiet and unchanged as to price.

The iron and steel industry continues to break records both in production and prices. Some eastern Pennsylvania mills are asking and getting 3c. for steel-plates, and are so busy that they declined to consider an order for 7000 tons from the Pacific Coast, despite the fact that plates of but one size were called for, and that such an order would ordinarily be considered most desirable. In January, 3,188,344 tons of pig iron (102,850 tons per day) was made. The number of furnaces in blast is being increased. In some steel products certain of the mills are sold up for the year. Prompt 80% ferro-manganese (used in the manufacture of steel) commands about $200 per ton, and material running less in manganese has been sold at $2.50 per unit of manganese.

COPPER

With the producers of electrolytic sold up until April, and deliveries in that month becoming more scarce; with the Lake producers sold up to June, 30c. copper seems not far off. Practically no re-sale lots are offered, at the market or under it, and it can be repeated that the producers have things in their own hands. Late last week, and up to February 2, the market was quiet, but nevertheless steadily growing firmer, and on that date a flurry of activity sent the price of nearby deliveries to 26c., 30 days, delivered, or 25.87½c., cash, New York. Since then May copper has reached 26.50c. full terms. Most of the inquiry was for February and March positions. Buying for export has been active, and some particularly heavy inquiries have come from Italy. One producer was forced to turn down an inquiry for 9,000,000 lb. of electrolytic, inasmuch as immediate delivery was wanted. The London market has advanced almost from day to day, despite the effort of the British Minister of Munitions to keep electrolytic down to £100. To this end circulars were issued to the consuming trades requesting them to refrain from making purchases of electrolytic amounting to anything over 50 tons, and at not above £100, without reference to the Ministry. The effort has been futile, however, probably because of the great need of the metal for munitions work, and the fact that stocks abroad continue to dwindle. The New York Metal Exchange cables reported the total stock of fine copper in Great Britain and France, on February 1 to be 17,523 tons, a decrease of 1833 tons as compared with January 15. Electrolytic was quoted at London on February 4 at £128. Exports in January totaled 21,863 tons. The railroad-freight embargoes continue to make it difficult to ship into New England where immense quantities of copper are used. When the embargo was raised a few days ago there was such a rush on the part of shippers that the railroads were forced to again stop acceptances of freight. It now looks as if the embargoes will be alternately lifted and lowered for some time to come. One wire-mill in the Naugatuck valley was compelled to shut-down for a few days, and other mills were near the danger-line because of low stocks. Reverting to domestic prices again, it can be said that not all of the trade is pleased with the way prices are soaring. They realize that the higher prices go, the greater will be the drop when the slump comes, and they remember the year 1907 when copper exceeded 25c., but dropped in the course of a few weeks to about 13c. Such declines are demoralizing.

ZINC

While some interest has been shown in nearby deliveries the market has been quiet for the past week. Until February 2 quotations eased off until 18.50c., New York, could have been done on that day. With the greater strength in copper, however, the spelter market showed more strength, and prompt was quoted on the 3rd at about 18.75c., New York. February was obtainable at about 18.50c., March at about 18c., and second quarter at 17.75 to 17.87½c. Prime Western is to be had easily enough at the ruling prices, but brass-mill special and the higher grades are scarce. January exports totaled 4812 tons.

Sheet-zinc is quoted at 24c., base, carload lots, f.o.b. mill, 8% off for cash.

LEAD

The lead market has been ruled by the strong foreign demand. While the New York price stood at 6.10c., New York, on February 3, sales for export were made at over this figure, and the trade was expecting an advance by the leading producer. Shipments against contracts are heavy, both foreign and domestic munition makers taking all they can get. The British munitions' authorities have tried to curb speculation in the metal and a slightly easier feeling has been created in London, where the spot quotation on February 3 was £31. All the producers are well sold ahead. January exports totaled 4210 tons.

TIN

Except for fair activity on one or two days the tin market has been quiet, and the trend of quotations has been downward. For spot tin 41.25c. was quoted on the 3rd. The situation is one where consumers' needs are covered. January deliveries totaled 4452 tons, and there was in stock and landing on the 31st 2401 tons; deliveries in January, 1915, amounted to 2480 tons. Of the January, 1916, arrivals, 1052 tons came *via* Pacific ports. On February 3 there was afloat 7670 tons. The British trade is quiet, and while there is a good demand in Europe, shipments to French and Italian ports is difficult because of the lack of ocean-freight room.

ANTIMONY

The market has gained considerably in strength because of the scarcity of prompt-delivery metal and occasional activity. At the beginning of February quotations were advanced to 43.50 to 44c., duty paid, for Chinese and Japanese grades.

ALUMINUM

In a quiet market, quotations are unchanged at 53 to 55c. for No. 1 virgin aluminum, 98 to 99% pure.

ZINC AND LEAD ORE PRICES

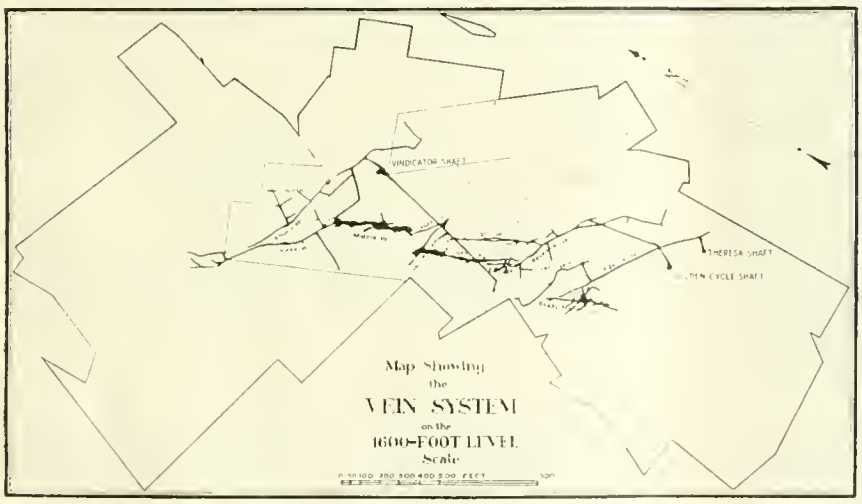
Prices for zinc-blende at Joplin last week were stronger, sales being up to $118.50, basis 60% metal. Production of the Missouri-Kansas-Oklahoma region was 6650 tons blende, 196 tons calamine, and 918 tons lead, averaging $110, $61, and $78 per ton, respectively. The total value was $819,062. For the first five weeks of 1915 the value is $3,802,045. A total of over $38,000,000 is expected for the current year, against $26,000,000 in 1915.

COMPANY REPORTS

VINDICATOR CONSOLIDATED GOLD MINING CO.

The report of this Cripple Creek company for 1915 is of considerable interest, which is increased by the plans and photographs. An important transaction was completed in March whereby the company purchased the mining property of the Golden Cycle Mining Co., of 43.5 acres, adjoining Vindicator ground, which now totals 130 acres, for $1,300,000. The assay, mine office, and engineering staffs were consolidated, also the air-compressing plants, while the machine-shops, boiler-plants, etc., will be, resulting in reduction of charges. Improvements at the ore-house enabled an average of 10,527 tons of ore to be handled monthly against 6358 tons before. Early in 1915 the new concentrating-plant, to handle reject from the ore-house and make a shipping product, was at full capacity; it is a complete success, treating 250 tons per 8-hour shift. Concentration is 11 to 1; the recovery from $2 ore was 55%. Profits from this plant are double what was expected from tests. Costs are 20c. per ton according to the report of Irving T. Snyder, vice-president and general manager.

The usual development and stoping operations were continued, with uniformly satisfactory results. Stoping on the large orebodies at 1600 ft. was vigorously prosecuted. The middle vein at this depth is 400 ft. long and 35 ft. wide. It is in ground previously regarded as barren. Its position is shown in the accompanying plan. So far at 1500 ft. this lode is 225 ft. long of good value.



The Golden Cycle shaft was sunk from No. 18 to 20 level, a depth of 2210 ft. The principal orebody, the Ready Money, was cut on No. 18 in April. On this level it is larger than on No. 17, but not so wide or high in grade. Since acquiring this mine the company has done a great deal of exploratory work. Lessees in both mines have done several thousand feet of development. The extension of the Roosevelt drainage-tunnel will cut the Golden Cycle shaft 65 ft. below No. 18 level. This will relieve the pumps at No. 18 and 20. A heading will be started from No. 20 to meet the drainage-tunnel. Pumping cost $41,273 last year.

Twelve months at the Vindicator and ten months at the Golden Cycle resulted as follows:

Crude ore extracted, tons	218,487
Shipping ore from above, tons	125,397
Average gold-content, per ton	$23.73
Company's share (76,209 tons)	$2,164,669
Lessees' share (49,188 tons)	815,183
Total	$2,979,852
Freight and treatment (company)	446,647
Gross proceeds for company	1,718,022
Net royalties from leasing	251,624
Total revenue at mine	$1,969,646
Mining, development, mill, etc	703,784
Profit from mining	$1,265,862
Sundry receipts	84,302
Total profit	$1,350,164
Paid on account of Golden Cycle purchase ($960,000) and other charges	1,046,939
Balance	$303,225
Cash on January 1, 1915	208,270
Total available	511,495
Dividends paid	225,000
Cash on January 1, 1916	$286,495

Liabilities include $340,000 Golden Cycle purchase notes outstanding.

Not less than 2,000,000 tons of $2 ore remains on the dumps, also large blocks of low-grade material in the mine, all profitable if a process for treatment can be devised. Since July two metallurgists have been experimenting with flotation and cyanidation. A 10-ton flotation plant is in operation. The tests resulted in the recommendation that the old Golden Cycle plant at the mine be re-modeled into a 300-ton flotation plant, sufficient to treat all the reject material from the Golden Cycle ore-house, as well as to experiment on all grades of ores. A recovery of 90% at a cost of less than $1 per ton is expected. Later a 1000-ton mill will be erected.

Workmen's compensation, a new law, has been carefully studied, and additional benefits were offered and accepted by the employees.

SHATTUCK ARIZONA COPPER CO.

This company operates at Bisbee, Arizona, and the report covers 1915. Development aggregated 14,978 ft. The orebody opened in the Southwest claim was the most important work; the shoot is 400 ft. long, 12 ft. wide, assaying 6% copper. The silicious gold-silver ore, with a small value in copper, is of importance, and is required at the Calumet & Arizona smelter. Large bodies of lead ore, distinct from the copper, have been opened also. Tests on the lead-copper-vanadium ores show good results.

The output was 11,154,211 lb. copper, 3151 oz. gold, and 201,869 oz. silver, a little higher than in 1914. The cost of copper was 8.45c., and average price 17.31c. per pound. The revenue was $2,368,548; profit, $1,174,028; dividends $875,000; and surplus, $267,664, compared with $1,660,573, $587,497, $525,000, and $31,865, respectively, in 1914.

The present monthly yield is 1,500,000 pounds.

PREMIER (TRANSVAAL) DIAMOND MINING CO.

Owing to the War this great diamond producer remained closed during 1915. An improved but limited demand set in early in the year, and some stones on hand were disposed of. It has been decided to resume washing operations on a small scale. During the year ended October 31, 1913, a normal year, there was 10,434,680 loads (1600 lb.) of ground washed, yielding diamonds worth 78 cents, at a cost of 60 cents per load.

BOOK REVIEWS

THE CORROSION OF IRON. By L. C. Wilson. P. 178. Index. The Engineering Magazine Co., New York, 1915. For sale by MINING AND SCIENTIFIC PRESS. Price, $2.

In recent years considerable investigation has been directed to trouble from corrosion, involving chemical research of no simple character. Results of these tests have been published by technical journals and societies, and are therefore difficult to obtain. This book contains a collection of the more important facts connected with the corrosion of iron and steel, and their protection from it. The rust problem is of great importance to constructing engineers and others. The three principal theories of corrosion are the hydrogen peroxide, carbonic acid, and electrolytic, these are well discussed. Various elements added to iron help to prevent corrosion, so do the many processes of coating with metals and paints. Engineers of all professions will find this volume of practical value.

INDUSTRIAL USES OF FUEL OIL. By F. B. Dunn. P. 232. Ill., index. Technical Publishing Co., San Francisco. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, $3.

The use of petroleum as a commercial fuel is still a comparatively new thing and there is but little technical literature upon the subject. The first chapter of the present volume discusses the heating value and other physical properties of fuel oil, comparing it especially with coal. The next chapters consider general arrangements and devices for oil burning, including pumping and storage systems, arrangement of furnaces, oil burners, strainers, and heaters. The use of oil in particular industries is then discussed, the clay, lime, cement, sugar, gas, rubber, and steel industries are taken up in turn, besides the use of oil in smelting and other metallurgical work, for locomotives, steamships, and for domestic purposes. The use of crude oil in Diesel engines is not considered. Considerable data are given regarding comparative costs of the use of oil and other fuels, and there are directions given for tests and reports on fuels.

ENGINEERING AS A CAREER. Edited by F. H. Newell and C. E. Drayer. P. 214. D. Van Nostrand Co, New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, $1.

This is a symposium on a much discussed subject, the contributors being A. J. Hines, Franklin De R. Furman, Worcester R. Warner, A. W. Johnston, Chester W. Larner, J. H. Herron, W. H. Abbott, M. C. Whitaker, S. T. Wellman, J. C. Workman, R. Winthrop Pratt, Robert Hoffmann, Rudolph Blankenburg, Frank C. Osburn, Benjamin S. Hubbell, F. B. Richards, Henry S. Munroe, Ernest McCullough, James F. Barker, Waldemar Kaempffert, David Edgar Rice, and John Ritchie, Jr., who discuss the engineer, boys becoming engineers, mechanical, railway, hydraulic, metallurgical, electrical, chemical, marine, sanitary, municipal, bridge, architectural, and mining engineering, also iron and steel opportunities for mining engineers, the lure of private practice, vocational guidance, income of technically trained men, and the technical man in business. Most of these articles were published in the Cleveland *Plain Dealer* and *Scientific American*. The inspiration for the book came in response to numerous inquiries from high school teachers and others who are frequently called upon to advise young men in their choice and preparation for a professional life. It was found from experience that many youths who planned to study engineering had only the most hazy ideas of what is involved, nor were their teachers and parents much better informed. The book should prove of special value to professional advisers in vocational guidance work and to parents who have the opportunity of continued observation and intimate acquaintance from which may be learned the aptitudes of their sons.

INDUSTRIAL NOTES

The AMERICAN MANGANESE STEEL CO., of Chicago, has opened an office at 202 Oliver building, Pittsburg.

The TERRY STEAM TURBINE CO., of Hartford, Connecticut, announces that Maynard D. Church has been appointed chief engineer.

Bulletin No. 49,200, from the Sprague electric works of the GENERAL ELECTRIC CO., discusses electrical theatrical devices, equipment, and accessories.

Catalog D, 1916, of the BROWN HOISTING MACHINERY CO., Cleveland, Ohio, describes tram-rail systems, trolleys, and electric hoists, made by the firm. In the 64 pages of illustrated matter there is a lot of useful information.

A 200-ft. thickener for the Inspiration mill, Arizona, some 50-ft. acid-proof thickeners for the Anaconda company, Montana; and six 40-ft. thickeners for the New Modderfontein mill, Transvaal, are being made by the DORR CYANIDE MACHINERY CO., Denver.

In Bulletin No. 60, the DENVER ROCK DRILL MANUFACTURING CO. describes its model No. 60, Denver 'Dreadnaught' driving drill. This is a machine weighing 83 lb. unmounted, and 140 lb. mounted, and suitable for one-man operation. It has a number of interesting devices to ensure good work. A few notes are given on the Waugh valveless stoper.

At the Wheeler copper mine of the Queen Regent Mines Merger Corporation, two miles north of Spenceville, Nevada county, California, Allen R. Partridge and M. M. Johnson are erecting a 11 by 18-in. new Partridge smelting furnace made by the PACIFIC FOUNDRY CO., of San Francisco. The daily capacity is 12 tons of ore, to yield 1.5 tons high-grade matte.

At Apollo, Pennsylvania, the Apollo Electric Steel Co. has been organized with a capital of $500,000 to make steel. Two SNYDER ELECTRIC FURNACE CO.'s Chicago furnaces are to be installed, each of 12 tons holding capacity, and with a daily output of 100 net tons each per full day. They will be basic lined. The Snyder company has opened a branch in England.

The New Cornelia Copper Co., at Ajo, Arizona, has recently placed an order with CHALMERS & WILLIAMS, of Chicago, for twelve 48-in. Symons fine-reduction disc-crushers, which will be the only crushers used in its plant to reduce 4000 tons per day from 4 to ¼ in. The firm also has on order one of the same kind of crushers for each of the following concerns: Chile Exploration Co.; Hollinger Gold Mines, Timmins, Ontario; and C. S. Christensen, Kristiania, Norway.

The Veteran Employees' Association of the WESTINGHOUSE ELECTRIC & MFG. CO., at its third annual banquet, held on January 29, at Pittsburg, presented to the company a handsome bronze memorial tablet of the late George Westinghouse, founder of the numerous industries bearing his name. Though only three years old, this organization, composed of those who have been in the employ of the company for 20 years or more, is one of the most active of the numerous Westinghouse organizations. About 450 veterans were present, and officers and men from the shop mingled freely with each other and discussed old times when the electrical industry was in its infancy. The tablet is 3 by 4 ft., of solid cast bronze, weighing 300 lb., showing in true bas-relief a likeness of the late master workman, inventor, founder, and organizer, from 1846 to 1914.

EDITORIAL

T. A. RICKARD, Editor

NOW that tungsten is in such demand, the scheelite that used to annoy the gold diggers on Snow and Glacier creeks, in the hills behind Nome, ought to be exploited to advantage.

COST of producing copper in the mines of North America may be taken at about 11 cents per pound of refined metal, including the expense of development. The cost ranges from 7 to 20 cents.

CARRANZA'S *de facto* government is being flouted every day that Villa remains on the rampage. Mining in Chihuahua continues to be menaced by Villa and his band. It would seem proper for Secretary Lansing to remind Señor Don Venustiano of his duty in the matter.

AT Cripple Creek the Vindicator Consolidated Company is to erect a flotation plant of 300 tons daily capacity, to be increased later to 1000 tons, for the treatment of the reject from the Golden Cycle ore-house. It is worth noting that the cost of this larger plant will be $200,000, as against $750,000 for a cyanide mill of equal capacity.

OUR friend *The Mining Magazine* has made the mistake—so it seems to us—of changing the name of its Précis of Technology to 'Mining Digest.' Of the latter there are many, and most of them furnish indigestible scraps of technical information highly provocative of mental dyspepsia, while the Précis of Technology prepared by Mr. Edward Walker for the pages of our London contemporary always seemed to us to be so peptonized as to permit of easy mental assimilation. Indeed, as we have said before, it represents an effort of good and sincere journalism, which it is a pity to label with a name so little distinctive as that which has now been substituted.

QUICKSILVER is a metal much in demand just now and the search for it is being stimulated in California by the abnormal price. We take pleasure in publishing a timely article by Mr. W. H. Landers, resident manager for the New Almaden Company, which is operating the famous old group of mines in Santa Clara county. He lays stress on the backwardness of mercury metallurgy and the lack of interest in the technique of the subject. Undoubtedly the stimulus given lately to the production of the metal will induce greater interest in the matter, for many deposits hitherto too low-grade to be mined will now attract exploitation. In this connection we may mention that cinnabar is one of the non-lustrous minerals that are amenable to flotation, so that we shall expect to hear of notable results. Our news columns this week make several references to the reopening of quicksilver mines.

ANOTHER uncommon mineral that has come into prominence by reason of the War is ozokerite or 'mineral wax.' As noted by Mr. L. O. Howard, in his Utah correspondence, the only two districts where ozokerite is mined in noteworthy quantity are Boryslaw in Galicia and Utah county in Utah. The devastation of Galicia, and the absence of exports from that province, has caused the price of the mineral to rise to 45 cents per pound. A mill for treating the Utah ore is to be erected at the Soldier Summit mine. In 1913 the quantity imported was 7,141,540 pounds valued at $549,990, or slightly over 7 cents per pound. Ozokerite is used largely for the manufacture of phonographic records.

METAL MARKETS continue to rise. Our correspondent at New York emphasizes the intensified demand for copper, and the reckless buying of this metal. A price of 30 cents is likely soon. Zinc also is soaring to new records. Lead is higher. Antimony is scarce. The tin smelter of the American Smelting & Refining Company at Perth Amboy has started to work, but operations are crippled by the interruption to shipments from Bolivia owing to the blocking of the Panama Canal. As we have said before, any mining company selling metals on the quotations of our New York contemporary should, at least, protect himself by taking heed to the prices we quote. Our source of information is wholly independent of the metal-selling agencies at New York.

LEGISLATION likely to injure the Bureau of Mines is threatened by the bill H. R. 153, which seeks to create a Bureau of Labor Safety in the Department of Labor, and by H. R. 9420, which aims to transfer the Bureau of Mines bodily from the Department of the Interior to the Department of Labor. We urge the friends of the U. S. Bureau of Mines not to overlook the danger of a hasty change that will end or cripple all the good work now under way. Important legislative measures do occasionally slip through owing to mere oversight on the part of those having real interest in the subject. The Mann bill, H. R. 153, passed the House on January 19, after it had been amended by a provision stating that "nothing in this act shall be held to repeal, modify, or affect any other Act of Congress" already in force. This proviso is supposed to save to the Bureau of Mines its labor-safety work, but it would not prevent the Bureau of Labor Safety from duplicating a great deal of

the work being done by the Bureau of Mines, and thereby undermining its status. In the bill making appropriations for the Bureau of Mines this year it was provided that no part of the $100,000 appropriated for metal mining work should be used "for work authorized or required by law to be done by any other branch of the public service." It is obvious, therefore, that there are influences at work inimical to the Bureau of Mines, which has won the cordial esteem of the mining public and deserves to be upheld in every way possible. Write to your Senators and Congressmen and tell them what you think about it.

AMONG the ailments to which the miner is subject is hookworm. In bringing about an investigation of this disease in Californian mines the Industrial Accident Commission is giving further proof of its great usefulness. Thanks to the Commission, the State Board of Health and the Federal Government have been prevailed upon to join hands in an effort to stamp out this disease in the mining camps of this State. The Board of Health has assigned Dr. J. G. Cumming, of the Bureau of Communicable Diseases. He will have charge of the medical part of the work, which will consist largely of making diagnoses and working out the system of treatment. The U. S. Bureau of Mines has assigned Mr. Joseph H. White, sanitary engineer, whose work will be chiefly that of examining mines with a view to devising means for combating insanitary evils. Mr. White arrived in San Francisco some days ago and is now at work in the Mother Lode region. Dr. Cumming recently made a short trip through several of the larger Mother Lode mines for the purpose of determining if hookworm infection existed. While the report on this preliminary investigation has not been published, it appears that at one large mine 40% of the miners were found to be infected. Should this percentage hold elsewhere, obviously it will be a most serious matter. The cause, effect, and cure of the hookworm disease are no longer obscure or hidden from the scientific eye. During recent years the subject has received a great deal of attention from various sources, the Rockefeller Institute having spent in the neighborhood of a million dollars in its work of investigating and eradicating the disease. The cure is well known and is quite inexpensive.

STANDARDIZATION of screens has not been accomplished as yet, apparently. Among the reforms brought forward for discussion by the Mining and Metallurgical Society of America by its committee on standardization is that of a scale for measuring screen-openings. At the recent meeting of the local section of that small but energetic society, it was voted to adopt the suggestion brought forward by Professor E. A. Hersam, of the University of California. We publish a letter from him on the subject, so that it may be properly ventilated. Hasty action is to be deprecated, for the adoption of any new standard means the upsetting of the good work done by the Institution of Mining and Metallurgy. Not that the decisions of the latter are to be accepted as beyond cavil, but it is well in these matters of international usage to take pains to obtain a consensus of responsible opinion. In the December issue of *The Mining Magazine*, Mr. Walter McDermott writes suggesting that the Mining and Metallurgical Society consult with the Institution before committing itself to the adoption of a new scale of wire-cloth screening. The choice of a standard by the Institution followed a ballot of its membership after consultation with the representatives of other societies abroad, and it has been found most useful in practice. In short, if any change is to be made, it should be made deliberately and considerately, with the view to general adoption in all the English-speaking mining regions. We venture to express dissent from a suggestion appearing in the Canadian Mining Institute bulletin, that the two engineering organizations mentioned above are "the two representative societies of the mining profession in the English-speaking world." This is a pardonable error. The 250 members of the M. & M. Society are gentlemen of unusual intelligence and distinction, but to assume that any group of 250 men represents or expresses the activities of the mining and metallurgical profession in the United States, let alone the not inconsiderable remainder of this continent, is a gasconade. The American Institute with its membership of 5000 may be too inclusive to be select; certainly the M. & M. Society with its 250 is too exclusive to be representative.

Physics of Flotation

A notable turn of interest has been manifested during the last six months in regard to this subject. It remains a remarkable omission on the part of the International Engineering Congress and the American Institute of Mining Engineers that the meetings of these organizations in San Francisco last August should have passed without the presentation of any paper on the particular metallurgical process that then, as now, commanded the attention of wide-awake technicians. However, that curious omission has been remedied since then. We have done a little ourselves, but the more important fact is that the local sections of the American Institute have shown commendable initiative in bringing the subject forward. Our friends at Salt Lake City did something worth while in December, the Arizona section is to follow suit, while the San Francisco division has devoted three meetings to discussions and demonstrations on the same topic. On the evening of the 15th instant, Dr. Joel H. Hildebrand, of the University of California, gave us a lecture on the 'Physical Phenomena Underlying Flotation,' accompanying his speaking by lantern exhibits. This was followed by a general discussion, in the course of which many interesting questions were asked and answered. The latter method of eliciting information is most to be commended, especially when it relates to a scientific study that is so far from being crystallized.

This meeting was also noteworthy in being a joint session of the 'miners' and the 'chemicals,' the local sec-

tion of the American Chemical Society having joined with the American Institute membership for the occasion. It is well for those who exploit one branch of science to go for help to the specialists in another department of knowledge. Just now the metallurgist happens to be in trouble; he has been called upon suddenly to face problems outside his ken. Hitherto his work has been based mainly on a knowledge of chemistry, but in flotation he faces phenomena the understanding of which involves such a familiarity with physics as he does not possess. Here we suggest that in the schools of mining, it will be well if the students make use of the instruction and laboratory facilities afforded by the physics department, and do not attempt to study flotation problems under the direction of professors of geology, mining, or metallurgy alone. We also commend to them, and to their seniors, a serious attempt to understand the terminology of the subject. The first step in any intelligent grasp of a scientific problem is the definition of terms. A phenomenon is an unusual appearance, and inferentially one hard to explain. When we don't know what a thing is, we are too apt to call it a 'phenomenon' and think that in so doing we have settled the matter. These Greeco-Latin terms are the mere smoke of intellectual exchange. We need, for instance, to understand clearly what is surface-tension, what is emulsification, even what is oil. The test of our knowledge will be the ability to explain any of these in Anglo-Saxon words of not more than two syllables.

Stoping Methods

No part of technical literature is so incomplete and unsatisfactory as that relating to the actual mining of ore underground. Such work is usually done by men not given to writing and it involves procedures not lending themselves easily to description. Moreover, it is a part of the operations that is apt to escape criticism because so few are equipped by knowledge or experience to pass judgment. The average director and mine-owner can see for himself if the books are kept properly, if the assay-office is clean, and if the mill is running smoothly, but when he goes underground he becomes merely a passenger. On the other hand, the actual conditions modifying the extraction of ore vary so much, both as regards lode-structure and metal-contents, as to check a hasty opinion on the part of any intelligent visitor, no matter how experienced he may be. While the simpler methods of attacking a plain problem in mining are well understood, it is recognized by the initiated that the larger and more complicated systems of excavation involve a variety of considerations far beyond the scope of any text-book knowledge or even conventional practice. It is difficult to depict or describe an elaborate scheme of stoping because all the phases of it cannot be seen at any given date in any single mine. The element of time is involved. Thus the technology of the subject is unavoidably incomplete. Yet it is one that should be brought forward for discussion at intervals. We are glad therefore to be able to publish an article by Mr. F. W. Sperr, Professor of Mining in the Michigan College of Mines. As will be seen, we give the information in the form of question and answer, believing that thereby it is possible to get more quickly at the root of the matter. It is proper that this article should emanate from Michigan, for in the iron and copper regions of that State have been evolved most of the methods of big-scale stoping that are now in vogue. The Professor divides stoping methods into three classes, according as whether (1) the stope is kept open, (2) filled with broken material on which the miner can stand, or (3) caused to cave. This is a logical classification. It is true also, as he contends, that several variations of open-stope methods are assumed incorrectly to belong to the much-abused 'caving' type. Such an idea frequently prevails in regard to sub-level stoping. Other points made clear in the article are the real significance of the term 'shrinkage' and the essentials of block-caving. This last system of stoping has the excellent characteristic of grinding a big orebody of medium-hard ore into small fragments and so entailing the consumption of a minimum amount of explosive, because, when it is under-cut, on the bottom and one or more sides, a block of ore several hundred feet square will crush itself by force of its own weight so as to be ready for shoveling. This process of grinding into small fragments requires an interval of several months after the under-cutting has been done, during which time this part of the orebody is let alone, while operations are being pushed in some other part of the mine. Incidentally, these big-scale methods demand enormous orebodies for their effective application, as the units of space and time are large. Just how the self-reduction of a block of caving ground is accomplished automatically is not entirely understood, for it is dangerous for the inquisitive to watch Nature in the art of mining. It is only known that in the sequel, when the ore is drawn, the crushed material settles down fairly uniformly.

The square-set system was introduced in the Ophir mine, on the Comstock lode, by Philip Deidesheimer in 1860, but this method of holding ground, like many other extravagances adopted at Virginia City in the boom days of an early decade in Western mining, has been superseded by the better methods evolved out of Lake Superior practice in the big iron and copper mines of Michigan and Minnesota. From the Lake country they have been borrowed by those exploiting the disseminated copper type of ore deposit in Utah, Arizona, and New Mexico. What the German or the Cornish miners gave to the American superintendent has been covered long ago by later accretions of knowledge. Big-scale mining methods are now truly American. They represent a scientific effort to exploit huge orebodies of irregular shape but relatively uniform composition so as to avoid the use of timber and shovel. No finality of procedure has been reached and every new problem has to be tackled on its merits, so that the subject continues to be one well worthy of frank discussion. We hope that some of our readers will contribute comment and criticism.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Designation of Screen Sizes

The Editor:

Sir—The action that is being taken by the Mining and Metallurgical Society of America for the betterment of practice, and the adoption of standards, is deservedly drawing attention to the proper use of screens for sizing. The activity of this Society will be welcomed by many who have undertaken to use screens for exact purposes. All those who have attempted to compare and check their own results upon sized products with like results obtained by other men, will find the appeal of the Society a timely one. The outcome of the movement should be a clearer understanding and better agreement in everything that relates to the sizing of products.

To disturb present fixed practices, however, is unwarranted, if there cannot be seen a way clear to an end that will be satisfactory and permanent when attained. The inconveniences which people are now experiencing in the use of screens are not restricted to a single item, but are general and varied. There is doubt if many are aware of the benefits, in detail, to be secured by a movement in which many men are to take a part. When all is done, much will still be left to common-sense in the use and selection of screens, and much left to personal preference.

The method of manipulating screens in sizing, the choice of the metal composing them, the preference for type and make, and many minor matters in selection and operation that a locality might require or an individual prefer are not details to be prescribed off-hand. The understanding of terms, however, and the general use of such designations as can be understood are advantages to be secured by public interest at this time, and these alone will justify the movement.

We are at present using specifications and terms that are indefinite. Many of us are unaware of the inaccuracy of the screens that we employ. Some of us have never properly taken into account the diversity there is in the size of particles when separated by the best of screens in the best possible way. Some of us would consider inaccurate the results of tests properly qualified by the percentage of error that work with screens actually demands. Our attention to the arrangement of a graded series, in great detail, must not lead us to forget that a limited degree, only, of accuracy is possible in the use of screens, nor lead us to suppose that we have fulfilled all that requires to be done in perfecting and designating screens when we have adopted a standard. In order to know of the degrees of accuracy, and to have methods of gradation and comparison capable of adaptation and improvement, we need results, not in the empirical numbers of screens, but in terms of the dimensions of orifices. In such terms as give results in actual orifice dimensions, and only in such terms, can a tangible and comprehensible expression of the coarseness of a sized product be obtained.

We describe loosely, at present, a material as being, for example, of the coarseness of 80-mesh. The statement is simple: It carries to most people a definite idea. The idea, however, is not definite in any material result it represents. It is true that '80 mesh' suggests a screen in which there are 80 openings per linear inch. No one now grades his screens by the openings numbered in a square area. General usage, moreover, would prompt one to interpret the statement as implying that there are 80 openings to the linear inch measured in a direction parallel with the wires.

Whether the material understood as sized by this so-called 80-mesh screen would barely pass the screen, or whether this screen on the other hand would obstruct the material after it had passed the next coarser size, we are not so certain. We generally infer that the material could pass an '80-mesh screen,' but that by the 90-mesh it would be retained. There is, however, always the possibility of misunderstanding in designating sizes in this way.

While we are sure that the openings of the screen are not larger than one-eightieth of an inch, since there are 80 of these openings to the linear inch, we do not know how much smaller than one-eightieth of an inch such openings may be. The space for the wire must be deducted to show this dimension. The size of the wire thus becomes a factor in designating the coarseness of a sized product or of a crushed ore.

Wire must be large for strong screens, for rough service, or for the weaker metals. Thus it is not suitable to adopt one size of wire for screens universally, nor for screens of one mesh or coarseness. Knowing the number of meshes to the inch and the size of the wire, it is possible to divide and subtract, and finally to arrive at the real dimension of the openings. The operation necessary in order to find the dimensions of the openings, of a screen one is contemplating, becomes a distraction from the real purpose. It is a troublesome and needless detail, and should be so dealt with as to be avoided. It is the opening, and not the wire, that is the real and important feature of the screen. The effect of the size of the wire

throws the critical and essential feature of the screen into a secondary consideration. The apertures of the screen become repositories for errors; and the essential dimensions become distorted to suit the possibility in combinations.

Knowing the size of the openings of the screens that are used for sizing, and designating the coarseness of sized products by these sizes is, without question, the most exact, adaptable, and direct means of expressing sizes. An attempt to measure particles under the microscope, or to weigh numbers of separate particles, and to average the weights, leads to error in corresponding ways as great as is met by sizing with good screens.

Angular pieces of crushed material are generally considerably smaller than a theoretical cube would be of a given dimension. The variation of the actual mass from the size of this cube depends upon many conditions into which the establishment of standards can never enter. Among many of the conditions influencing these sizes will be the dampness of the material, the cohesion, and the angularity; and when results come from questionable sources allowance must be made for the possible incompleteness of manipulation upon the screen, for the spread of wires, and for the imperfect condition of the screen.

The universal expression of the coarseness of material, as time goes on, will come to be in terms of the coarseness of the screens that were used in sizing it. To number such screens in any way other than in the dimensions of their openings will therefore be found needlessly indirect. Numbers arranged for any special series or limited to any special trade interpretation will be found without convenience or justification. The expression of screen sizes by the dimensions of the aperture is simple, direct, and sufficient, and the establishment of a general custom of so representing screens should be the prime object in the present movement.

Our present standards are under the English system, and common agreement appears to have adopted the units of this system for trade and common measurements. The unit of the thousandth of the inch is convenient in magnitude for the measurement of fine screen-openings. Upon this basis, all results of work with screens, all tabulations of their sizes, all designations of any series of screens, and all specifications of screen sizes should be expressed in whole numbers representing the thousandth of the inch, adding, if desired, or if necessary, any needed fraction of the thousandth thereto in the same manner in which use is made of inches and quarter-inches in larger measurement. It is desirable, permanently, to discontinue allusion to the number of openings to the inch as an expression of the coarseness of the screen. Allusion to the size of the wire properly should be for reference to the strength, or the wear, or the metal, or the ratio of discharge-area to structural substance, but not to the coarseness. A screen having openings 0.050 inch in dimensions, as thus considered, would be one designated by the number 50. This number being the dimension of the opening in standard units commensurate with the magnitude of the openings to be considered. With these numbers, and with the variety of screens the trade now supplies, we can secure such a series of screens as may be desired. Our idea of the coarseness of products will then rapidly take form in terms of these dimensions.

ERNEST A. HERSAM.

Berkeley, January 10.

Simple Problems in Flotation

The Reader:

Sir—On another page Mr. Durell objects to a statement of mine in regard to the floating of an ungreased needle on water. He is measurably right. An ungreased needle will float, but not nearly so easily as the greased one. The latter will float if placed on the water without special care, but if the former is handled in the same way it will sink. My reference to the matter was quoted from the 'prior art,' which in this regard, as in many others, I know now to be a dangerous guide. Some time ago, but since my first writing on flotation, last summer, I made several experiments to find out for myself what happens. To be certain that the needle was free from grease, I dipped it in a hot solution of washing-soda and then dried it, taking care to use a clean cloth and to not touch it with my fingers. Then I placed a piece of tissue-paper on the water in a cup and laid the needle upon it by aid of a pair of pincers. The tissue-paper was depressed into the water, becoming wetted gradually, until it was all soggy and finally sank, leaving the needle floating. Without such care I could not make the needle float.

Next I used the camphor test to ascertain if the water had been contaminated by grease. If camphor is whittled with a knife above the water, the shavings will dance on the water in a life-like manner suggesting insects in a fit. This phenomenon, as shown by Marangoni, is due to the dissolving of the camphor, preferably at its pointed end, where a maximum surface is presented to the water. The solution decreases the surface tension of the water in contact and thereby causes the uncontaminated water, with its stronger tension, to pull away from the spot affected by the camphor. In order to produce this activity of the camphor, the surface tension of the liquid must be greater than that of the camphor solution. Hence if grease be introduced into the water, thereby lowering its surface tension, the camphor becomes inert. If, while the camphor particles are active, the water is touched by a greasy finger (all fingers are a little greasy) the camphor becomes quiet immediately. This furnishes a good test for the presence of even a trace of grease. No ordinary 'clean' cooking utensil is sufficiently free from grease to allow an exhibition of the camphor dance.

To return to the floating ungreased needle. I introduced some camphor shavings, and they were lively. Then I repeated the experiment with a needle that was slightly greased, and the camphor seemed to be unaffected thereby. Finally, I smeared the needle with olive oil: an iridescence on the surface of the water

indicated diffusion of the oil. This time the camphor chips fell dead on the water, and remained wholly inert. Apparently therefore the needle will hold to itself a limited amount of oil or grease, which adheres so selectively as not to contaminate the water. But any excess of oil, more than the needle can hold, will be set free to modify the water and lower its surface tension.

Of course, there is a limit to the size of needle that can be floated. When the needle is floating it lies in a dimple or depression; if the needle is so heavy as to overcome the surface cohesion, the sides of the depression meet, and the needle is engulfed in the water. Bubbles of air can be seen attached to the needle when floating. The film of air is not continuous. Apparently the flotation is due to the resistance of the water surface to rupture, this resistance being caused by an elastic force that permits the water to yield in the form of a dimple. Moreover the air bubbles add to the buoyancy, both by their less specific gravity and by preventing the curved walls of the dimple from meeting overhead, that is, by widening the angle of contact. As the proverb says, "oil and water will not mix"; the adhesion of air to a metallic surface is matched by the molecular repulsion between the oil and the water.

As Mr. Durell suggests, the fact that grease is not essential to the floating of the needle is symptomatic of the trend of the flotation process. The oil is important chiefly as a means of lessening the surface tension of the water and so yielding air bubbles that will last long enough for the work of buoying the mineral particles.

In regard to the experiment described and discussed by Messrs. Durell and Norris, I have tried it and I recommend every student of flotation to try it, watch it, and cogitate on it. If kerosene oil is poured over colored water and air is blown into the lower liquid, a number of interesting phenomena can be observed. Mr. Durell sees bubbles enclosed in a film of the colored water rising through the oil and breaking at the surface, while the colored water of the bubble-film drops back through the oil exactly as a balloon on bursting drops to the earth. Mr. Norris conducts the experiment in two stages: in the first, he blows air gently and sees colorless bubbles rising through the colored water to the surface of the overlying oil; he says that these bubbles show no trace of color, and they are unaccompanied by a return passenger of colored water. He concludes that the bubbles have no film, but are simply holes in the water and oil successively. In the second stage of his experiment, he injects air with greater pressure, making larger bubbles, which pull the colored water to the surface of the oil. The bubbles are not colored, but they take with them flat portions of the colored water, which fall back when the bubble reaches the surface of the oil.

I have conducted the experiment many times, and my report is as follows: when the air is injected into the oil, the bubbles are short-lived, but they last long enough to prove, as we know already, that the oil is not a pure and perfectly homogeneous liquid. In such a liquid bubbles would not survive. The fact that two bubbles can touch without coalescing proves that there is a film or membrane separating and surrounding them. When I blow air gently into the colored water, the rising bubbles are colorless. They accumulate at the surface of the oil, and show an attraction for each other, and for the sides of the glass vessel. These bubbles appear to last longer than those blown in the oil. Next, when I inject air more rapidly into the water, a bubble appears at the point of a cone or mound, as if it were dragging the water-surface with it. This bubble will remain poised for awhile at the peak of the mound of water before breaking away, and rising, while the water falls back. If the air be injected still more rapidly, the bubble breaks through the water-surface, appearing to tear it, and takes with it a portion of water. This is attached to the south pole of the bubble and may accompany it to the surface, where, on arrival, it drops away in a curious crescent form. If I introduce air still more rapidly, the water-surface is torn into pieces of odd shape.

The bubbles in oil are round or spherical; those generated in the water, as seen in their passage upward through the oil, are flattened; they are oblately spheroidal. The colored-water drop that leaves the south pole of the bubble, on its arrival at the surface, is also flattened; if small, it is crescent-shaped; if larger, it is oblately spheroidal.

It will be noted that I have said that this and that "appears" to take place. The difference in description by various observers indicates how difficult it is to see correctly. These are truly 'phenomena,' or appearances that are unusual and hard to explain.

As to Mr. Norris's idea that the bubble is simply a hole in the liquid, I would suggest that a globule of air takes to itself a film when in an impure liquid, that film consisting of some impurity or contaminant in concentratable form. Thus the hole becomes a sac. As the colored water and the kerosene are both impure liquids, we may infer the existence of a film on the globule of air, as indeed is proved on its arrival at the surface, where bubbles remain in contact without coalescing. The next question arising is as to what change the film of the bubble undergoes in the passage of the bubble from one liquid into the other. The watery film would, I suppose, be affected by coming in contact with the oil, and it would seem to me *a priori* that the bubble would arrive with a film of the liquid having the lower surface tension. This is a point I would like to refer to our friends, Messrs. Ralston, Durell, Norris, and Coghill, all of whom have contributed so generously and so usefully on the theory of the subject. That theory is no mere academic exercise: it is at the very base of any reasoned understanding of the flotation process.

T. A. Rickard.

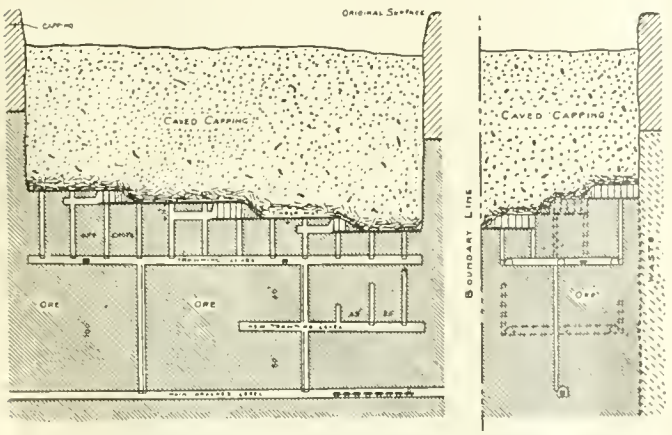
San Francisco, February 11.

Rutile (titanium dioxide) production of the American Rutile Co., the only producer in the United States, was 250 tons in 1915, worth between $25,000 and $30,000. It is mined in Virginia.

Stoping Methods

By F. W. Sperr

[Descriptions of methods of stoping are usually dry and involved; it is frequently the case that a reader starting to read such an article abandons his good intention and decides to leave the perusal of the weighty treatise until he has more time—which never comes. Yet stoping methods are a matter of great importance. More than one mine manager has casually assumed that such-and-such a system of ore extraction would work out satisfactorily (perhaps the only method with which he was acquainted) only to face the fact later that the method is not practicable to the conditions, and that perhaps large blocks of ore have been lost through getting irremediably mixed with sand or waste. Then it is necessary to adapt another method of stoping to an underground development that was intended for some other system; the changing of stoping methods at an operating mine resembles "swapping horses while crossing a stream." The difficulty in disseminating knowledge about stoping methods lies in putting it in shape so that someone will read it. To bring out a few essential points about methods of stoping, we invited Mr. F. W. Sperr, the Professor of Mining in the Michigan College of Mines and an acknowledged authority on the subject, to answer several questions. The questions with the answers are as follows.—EDITOR.]



Longitudinal Section. End Section

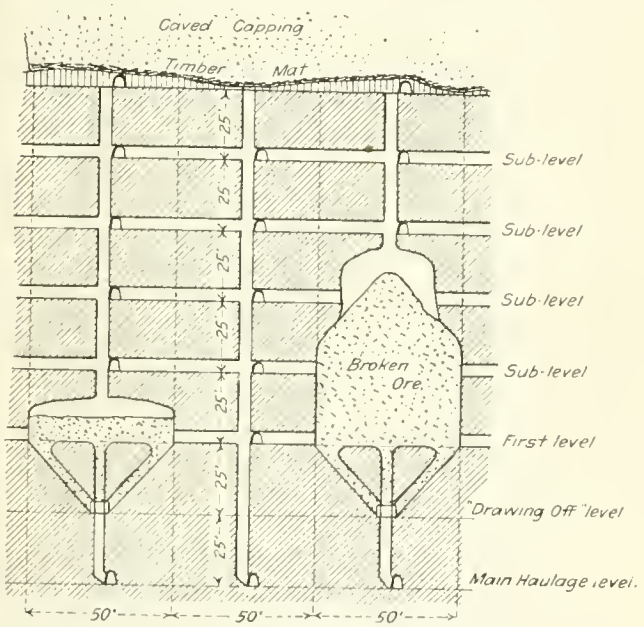
TOP-SLICING IN THE HUMBOLDT MINE, ARIZONA.
(From P. B. Scotland's paper, Bulletin A. I. M. E., Feb. 1915.)

To what kind of an ore deposit is mining on square-sets most applicable?

Square-sets are competent to form a skeleton-work in an open stope for the purpose of preventing fragments of rock falling out of the walls and back; and also to serve as an index in case any heavy movement of rock is likely to set in. As to what kind of an ore deposit mining on square-sets is most applicable, I would say a deposit which can best be mined in open stope, except for danger of falling fragments, and which is too wide for the use of props or stulls; or a wide deposit under a strong and clean hanging-wall or capping, which becomes dangerous soon after it begins to 'take weight,' when the timber merely indicates what is coming. Sometimes such walls or cappings settle gradually without danger and no timber is used under them.

Do you consider that the square-set system or method of mining is being used more than is warranted; that is, where some less expensive method would seem to be better adapted?

The square-set system has been crowded out of many mines by better systems, and undoubtedly needs to be crowded out of many more. But a change of any system usually means a change of supervision, because the underground foreman knows what to expect from the method in use, and very naturally dislikes to try a new method with the behavior of which he is unfamiliar, unless the new method is one which he has thoroughly worked out for his own.



AN EARLY STOPE AT THE MIAMI.

Should a distinction be made between the terms, 'stoping method' and 'mining method'?

Yes, properly speaking. For example, we have the block-caving method of mining by cave-stoping; the top-slicing method of mining by cave-stoping; the top-slicing method of mining by open-stope; the sub-stoping method of mining by open-stope; the sub-stoping or sub-slicing method of mining by cave-stoping; the square-set method of mining by open-stope or filled-stope; the

room and pillar method of mining by any of the methods of stoping, etc.

It would appear that the use of the term 'caving' applied to mining is much overdone. What is the proper meaning of caving as used in mining?

The term 'caving' is about as distinctive as the term 'stoping,' and perhaps it may as well remain so. It is comparatively new, to be sure; but people will soon learn that when they say "the mine is worked by the caving method" they have not expressed themselves definitely. The term now covers every method by which the overburden, or the ore, or even the filling in the stopes, is made to move downward by means of cutting the support from underneath. In 'top-slicing' we have the caving of the overburden; in 'sub-slicing' we have the caving of the ore and overburden; in 'block-caving' we have the caving of the ore with or without caving the over-burden; and in 'back-filling on floor-pillars' we have caving the filling when the floor-pillars are being mined out. Room-and-pillar stoping, followed by caving the pillars and overburden, is recognized as caving.

Does that mean that you divide underground methods of stoping into three classes based on whether: (1) the stope is open; (2) partly filled with broken ore or rock on which the miners stand to reach the back; (3) filled by rock or ore that follows or caves as extraction proceeds?

In that case we would have the 'open stope,' 'full stope,' and 'caving' as the primary subdivisions of stoping methods. But what shall we do with the 'full-stope-and-caving-the-filling' method? There always will be hybrid methods that cannot be distinctively classified. Perhaps, however, you should add a fourth class, depending on whether the stope is divided into chambers by pillars of ore; and let it go under the designation of the 'room-and-pillar' method. This should include the method of mining the Treadwell lode, as described by T. A. Rickard;[1] the methods of mining at Miami, described by R. L. Herrick;[2] the method of mining at Ray, as described by Lester A. Blackner;[3] and many other methods. Properly speaking, however, the 'room-and-pillar' system is a 'method of mining' in which any or all of the methods of stoping may be employed. In reality there are but three methods of stoping (1) the open stope (2) the filled stope and (3) the caved stope.

What is the significance of the term 'shrinkage' as applied to stoping methods and to what variety of ore-body do you consider a shrinkage system best adapted?

The term 'shrinkage' has been invented to signify what was long known as 'overhand stoping on broken ore' or simply as 'back-stoping on ore.' I prefer the older expression, because its significance is at once obvious to mining men. The newer term has led to such expressions as "we are mining the ore by shrinking it," and "we are shrinking the stopes," which, I think, are absolutely indefensible. What could be more lucidly expressive than "we are back stoping on ore?" (The evolution of terms is often interesting; and right here I would like to record one which is just now in the making: the use of the term 'hanging wall' has been well established, but it is in danger of being displaced by a new term. For short, it is called the 'hanging;' the Cornish miner calls it the 'angin';' our Italian miners, not quite catching the full enunciation of their English speaking fellow-workmen call it the 'angle-wall,' and already now and then, one will hear a Cornish miner call it the 'hangle.') The method of back-stoping on ore is best adapted to ore-bodies with strong walls, tough backs, and enough dip to allow the broken ore to follow down freely when drawn off at the bottom. The term 'shrinkage' to designate overhand stoping, or back-stoping, on broken ore, I believe, was first used by F. Percy Rolfe in a paper presented to the Institution of Mining and Metallurgy and published in Bulletin 55, February 11, 1909. It may have been suggested by the miners' explanation that they 'shrunk' the pile of ore when it got too high in the stopes for their convenience. In the discussion of the paper Edward Hooper regrets that the subject has not been dealt with by some one with more intimate knowledge of methods, but admits that the paper is a most creditable one to have been written by a student; and proceeds to apply the term 'shrinkage' to the method in use at the Alaska-Treadwell mine as described by Robert A. Kinzie in a paper presented to the New York meeting of the American Institute of Mining Engineers in October, 1903. But we note that Mr. Kinzie had not yet learned that he was describing the 'shrinkage' method. In all the discussion there appears one protest against the use of the term; Henry Louis points out that the method differs but slightly from the one he has described as 'magazine mining.' It is truly wonderful how generally the old hands fell in with ('fell for' to be more modern) the use of Mr. Rolfe's term. It is a pleasure to see a student get his dues. Le Neve Foster, in his excellent book, 'Ore and Stone Mining,' 1894, page 330, and in subsequent editions, refers briefly to the method as the obvious thing to do in overhand stoping when there is nothing except broken ore conveniently at hand to stand on. But it was left for a student to whom it was new (and no doubt wonderful) to make an elaborate description and give it a name in literature. Of course, 'magazine mining' could hardly hope to meet with popular favor; but every English-speaking miner catches the idea when he hears such an expression as, for instance, "we b'long to shrink the pile." In the Lake Superior region, the term 'shrinkage' has come a little into use among practical mining men, but apparently it has come in 'from the surface' through some of the men who read technical mining literature.

What common systems of mining would you classify under the open-stope method?

Back-stoping on timbers, and without timber where the dip is not too great to allow the miners to work up-

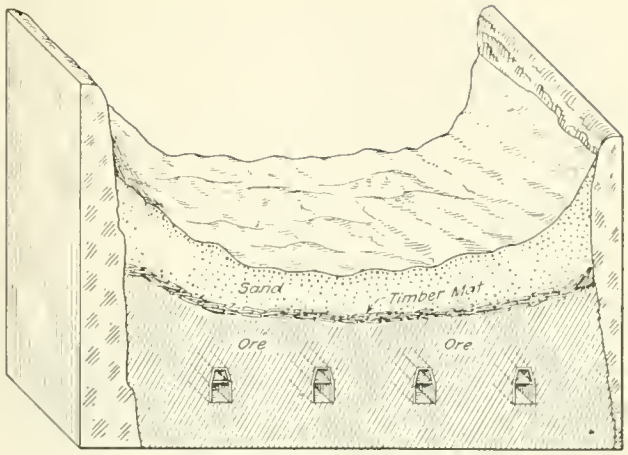

FIG. 2. BLOCK-CAVING CORRECTLY DONE.

ward on the foot-wall, which is commonly called 'back-stoping on the foot;' underhand stoping; sub-stoping; top-slicing and sub-slicing without caving the overburden.

Although it is impossible to generalize rigidly for hypothetical orebodies, what would be probably the most satisfactory method of stoping for a vertical orebody 100 ft. wide with firm walls considering that the ore is firm and homogeneous with no 'horses' of rock and that no underground sorting is necessary?

Either room-and-pillar or block-caving, or possibly sub-stoping, depending upon the texture of the ore. Block-caving would be given the preference if the ore would break fine enough in the process of caving and settling in the time that could be allowed between cutting-off and drawing-off. The sub-stoping method would be preferred if the ore is free from slips, rather tough, not so hard as to make the sub-drifts too expensive, and if the walls and capping are strong enough to allow large panels to be stoped. The room-and-pillar method permits of going through the orebody and breaking it up as fine as may be desired with drill and powder, provided that the backs are safe. The Miami system as originally laid out, was an elaborate room-and-pillar system where block-caving would probably have served to better advantage, see sketch. The Zimmerman mine in the Iron River district of Michigan, attempted block-caving without proper preparation, with the result something as illustrated in Fig. 1. The Ray system is room-and-pillar stoping, followed by caving pillars, broken ore and overburden.

CAVING OF THE SURFACE AT RAY, ARIZONA.

where the block-caving system might have found most excellent adaptation without any preparation of timber mat under the capping.

With the same reservation as to generalization, what would be probably the best method for a similar orebody to fit, wide?

Back stoping on ore. Either on arches or on stulls and lagging.

If the 100-ft. orebody were composed of soft wet ore of no firmness at all and the walls were not much better, what would be probably the best system?

Block-caving, preceded by drainage and proper preparation, and accompanied by skillful supervision; see Fig. 1 and Fig. 2.

What are the significant features of block-caving which is generally understood to be a comparatively new method?

The block-caving method of mining was introduced about twenty years ago in the Pewabic iron-ore mine at Iron Mountain, Michigan. The method was described by E. F. Brown at the meeting of the Lake Superior Mining Institute at Iron Mountain in 1898, under the title of "A System of Mining Orebodies of Uniform Grade." It may be said, however, that uniform grade of ore is not essential, but rather that a close selection of grades is impossible. The method soon became known as block-caving. It is distinguished from other caving methods by the depth of ore caved to the undercut. This depth of ore caved grades from zero in top-slicing, through sub-slicing, to the full depth from level to level in block-caving.

Block-caving methods may again be distinguished from each other by the different methods of making the undercut. In the Pewabic mine the conditions were favorable for making the undercut on the sill floor without timber; but timbered drifts through the caved material were used for the drawing-off. The capping was a strong, hard sand-rock that gave no trouble in becoming mixed with the ore. Under a different type of capping with a similar texture of ore, it has been found better to make the undercut on an arch above the haulage level in much the same manner as it is made in the other case on the sill floor.[4] The caved material is then drawn uniformly from all parts of the block through chutes closely spaced in the arch over the drifts and cross-cuts on the level. If the capping is of a certain texture like hardpan, it may follow downward without mixing with the ore; but if it is loose material like sand or gravel, a top slice of ore is removed and the space filled with timber to form a mat between the ore and the capping.

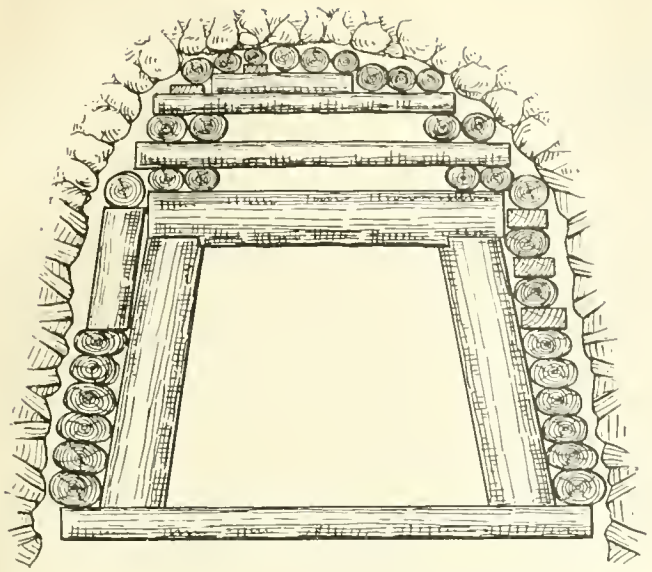
The difficult part of the operation, when the undercut is made on the sill floor, comes in the opening and maintenance of the timbered drifts through the caved material, for drawing off the ore. The chief difficulties in the operation when the undercut is made on a sub-level, come in maintaining the haulage ways and in breaking the large pieces that block the chutes. For removing a block of ore that has been caved to the sill floor, nothing better has been devised to take the place of the timbered drifts that have been used in the Pewabic mine from the beginning of block caving. But for removing the caved ore through chutes, some modifications have been made, both for breaking the large pieces of ore and for maintaining the haulage ways. At first it was the custom to break the chunks in the chutes by attacking them through the gates. This process has been facilitated in some of the mines by means of the double-deck timbered drift, and in others by means of sub-drifts between the haulage level and the under cut, thus giving access to the sides of the mills and allowing much of the breaking to be done with hammers which would otherwise have to be done with drill and powder at greater expense, loss of time, and often danger to the miner as well as to the chute.

The ordinary rigid method of timbering by means of legs, caps and studdles, requires a great deal of repair work in heavy ground. To alleviate this difficulty, a system of timbering has been devised on the theory of yielding supports. Instead of legs with the weight coming on the end-timber, blocking is used with the weight coming on the side-timber, with the result that a considerable downward movement can take place without destroying the drift. Instead of supporting caps and chute-gates by the same set of legs, the thrust on the caps is transmitted to the floor through independent sets of compressible blocking, preventing the lip of the chute being pressed below the top of the tram-car.

Furthermore, the method of timbering the drawing-off drifts on the yielding principle, not only reduces the cost of repairs, but also makes possible the maintenance of the drifts in heavier ground. Thereby a wider field is opened for the block-caving of orebodies that are too soft to stand undercutting without timber and are covered by a capping that does not permit the use of the Pewabic method of drawing the ore. Under an unfavorable capping that requires the ore to be drawn uniformly from all parts of the block, this method of timbering makes it possible to provide and maintain chutes in sufficiently close proximity to each other under the whole block, provided that excavations in the soft ore in its original, undisturbed position, will stand open in sufficient dimensions for a length of time to permit placing the timber. The existence of such a condition will be indicated by the manner in which the drifts stand without support when a level is first opened. Before movement sets in, an excavation in many soft-ore bodies will stand open for a long time without artificial support.

On first impression it appears that an excessive amount of timber is required for the yielding supports, but in fact the repair work is so little that the total consumption of timber is ultimately less by this method than by any other. The method of timbering described makes it possible to provide and maintain chutes in sufficiently close proximity to each other. It then becomes only a

[4]Described by F. C. Roberts at the meeting of the Lake Superior Mining Institute in 1911.



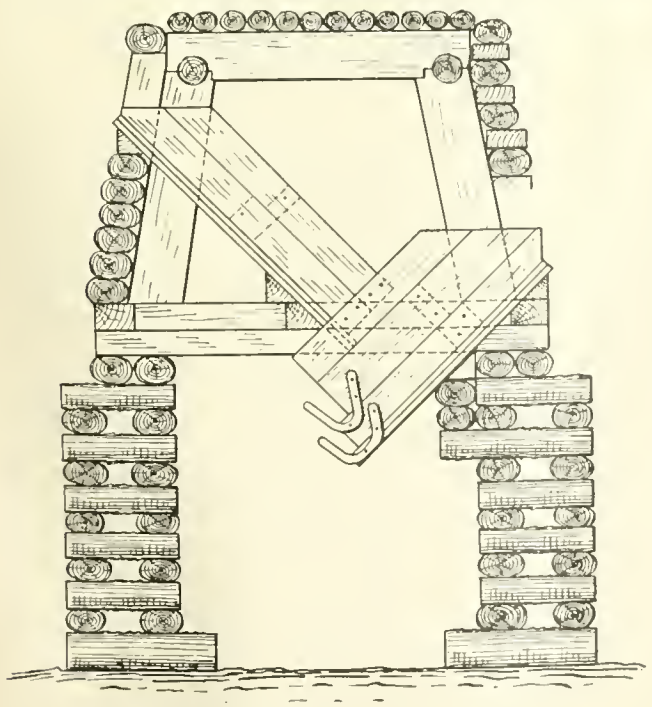
THE UPPER BENT IN TIMBERING FOR BLOCK-CAVING.

matter of finishing the undercut near the top of the timbers by barring operations through holes provided for the purpose; after caving begins, the ore must be drawn off fast enough to keep excessive weight off the timbers. Soft orebodies in their natural position are often able to hold in place without movement until they are almost completely undercut. By the block-caving method there is greater safety, greater production per man per day, a higher possible percentage of extraction, and the ventilation is better, beyond all comparison, than with any of the slicing methods.

What would be the probable best method for a similar orebody 10 ft. wide?

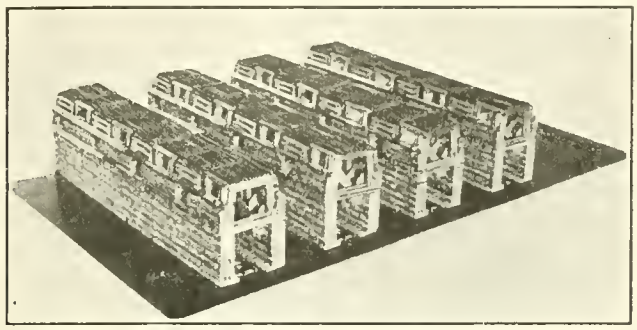
Top-slicing.

To what variety of orebody do you consider the dry-wall method as practised on the South Range of the Copper Country best adapted?



THE NEW TIMBERING FOR BLOCK-CAVING.

In the first place, there must be available suitable waste-rock for building dry walls. Then the orebody should be 15 ft. or more wide and steep enough to allow the selected ore to run readily through the chutes that are built upward from the dry-wall and surrounded with



A MODEL OF THE NEW TIMBERING.

filling material. The backs should be tough and strong, although protection against falling fragments can be provided by means of cribs and props.

Safety-First Exhibit

There will be held in Washington, D. C., during the week of February 21-26 inclusive, a safety-first exhibit in which all of the Government departments are taking an active part. This exhibit will take on a National aspect, as manufacturers and operators from all over the country are invited to be present, in order that they may see what the Government of the United States is doing in safety-first work. Franklin K. Lane, Secretary of the Interior, has sent a letter to the governor of each State inviting him to send a delegate, and asking that the chief mine inspector, a representative of the industrial commission, or of other agencies engaged in compiling statistics relating to the various mineral industries, also attend this exhibition. It is hoped that all interested persons will visit the safety-first exhibit, and will attend the conference of State mine inspectors, which will be held at the office of the U. S. Bureau of Mines, on February 24.

THE TAVOY DISTRICT, lower Burma, India, exported 1631 tons of wolframite concentrate in 1914. The ore occurs in arenaceous and argillaceous schists, pierced by granite, forming domes, which contain the richest deposits. Oxidation or decomposition, due to heavy rain, is extensive. Cassiterite occurs in the lodes, also molybdenite. The yield of over 18 months was 2.4%. The best product averaged 72.8% WO_3. Chinamen do most of the mining. In 1913 there were 2368 laborers. Machine-drills are not used yet. Selection of ore is done in the mine. Hammers and cradle concentrators are used to dress the ore, with much loss. Some alluvial wolframite is found. A royalty is paid to the Government.

Refining Cupriferous Precipitate

By Jackson A. Pearce

THE Argo mill, Idaho Springs, Colorado, is a custom mill treating ores assaying from a trace to as high as 3 or 4% copper. In the cyanidation of these ores much copper is taken into solution, and later precipitated along with the gold and silver in the zinc-boxes. While the copper has been no obstacle to satisfactory precipitation, it has greatly interfered with the refining of the precipitate.

In the ordinary method of refining, namely by treating with acid, drying, and melting, the bullion is never better than 750 fine in gold and silver, and frequently as low as 550, copper constituting the greater part of the 450 of base metals. The accompanying analysis of a sample of the untreated precipitate shows the high percentage of copper, and the normal ratio of the silver to the gold; the percentage of copper is not uniform, varying from 15 to 30%.

	%
Gold	4.3
Silver	13.8
Copper	21.6

This high proportion of silver precludes the application of the usual methods for the removal of the copper. The process of roasting with subsequent leaching of the oxidized copper is not only a tedious operation, but one in which the loss by dusting and by volatilization is high. The use of oxidizing agents, for example, manganese dioxide or nitre, for the purpose of slagging the copper is not applicable, since an appreciable amount of the silver is likewise oxidized and dissolved by the slag. Copper can be, and frequently is, removed as a matte, but as copper matte is an excellent solvent for gold and silver, the formation of sufficient matte to remove the 15 to 30% copper of the precipitate would remove a prohibitive amount of the gold and silver. Occasionally matte is formed in spite of efforts to prevent it, and the prevalent practice of converting it to an iron matte by the addition of scrap-iron would remove a large proportion of not only the gold and silver, but of the copper as well.

For 18 months I have been using successfully a wet method for the elimination of the copper. It consists essentially of the oxidation of the copper with the subsequent dissolution of the copper oxide by sulphuric acid. For oxidation I am at present making use of the time-honored action of sulphuric acid on manganese dioxide. Commercial manganese dioxide (pyrolusite) is used on account of its convenience and cheapness, although several of the higher oxides, including hydrogen peroxide, have given good results on an experimental scale.

The equipment necessary for the operation of the process is common to nearly all the refineries, namely, vats, filter, and furnace. The sludge from the zinc-boxes is treated with an excess of acid until action ceases. Pulverized pyrolusite then is added, in proportion to the amount of copper to be removed. I find that with this precipitate, 4 to 6 pounds of pyrolusite removes one pound of copper. A rough estimate is made of the amount of copper to be removed, and a quantity of pyrolusite considerably less than the estimated amount required is added to the charge. The charge is kept distinctly acid and in agitation. Evolution of oxygen proceeds immediately upon the addition of the dioxide to the acid. The nascent oxygen at once oxidizes the finely-divided copper, which, being oxidized, is immediately dissolved by the excess of sulphuric acid. Equations representing these reactions may be written as follows:

$$H_2SO_4 + MnO_2 = MnSO_4 + H_2O + O$$
$$Cu + O = CuO$$
$$CuO + H_2SO_4 = CuSO_4 + H_2O$$

Inasmuch as silver is analogous to copper, in that it is easily oxidized and the oxide is readily soluble in sulphuric acid, we should expect to have an appreciable amount of the silver oxidized and subsequently dissolved. Doubtless the oxidation and dissolution of the silver are among the many chemical changes taking place in the vat, but, owing to the presence in suspension of the finely-divided electro-positive copper, the silver at once is re-precipitated as metallic silver. The cycle of the silver may be expressed in this way:

$$2Ag + O = Ag_2O$$
$$Ag_2O + H_2SO_4 = Ag_2SO_4 + H_2O$$
$$Ag_2SO_4 + Cu = CuSO_4 + 2Ag$$

Accompanying a continuous evolution of oxygen there is a constant oxidation and dissolution of both copper and silver with a continuous replacement of the dissolved silver by the copper, until the metallic copper has been removed from the sphere of action. With the removal of the copper, the silver makes its permanent appearance in the solution and constitutes an end-point, so to speak, of the process.

Usually the first addition of manganese di-oxide is not sufficient to oxidize all the copper. If the manganese di-oxide is finely powdered and the solution hot and distinctly acid, the reactions are complete within a few minutes. When all action has ceased, the solution is tested for silver, using bromine water. With a precipitate containing as much as 20% copper the solution should be strongly colored with copper sulphate. If there is no indication of silver in solution, another, but smaller, portion of manganese di-oxide is added together with sufficient acid to maintain the acidity of the solution. A few applications of the chemicals in this manner

are usually sufficient to bring the silver into solution. All the copper now, except the few coarse massive particles that are generally found in the sludge, together with some of the silver, is in solution. Gold will not dissolve under these circumstances, notwithstanding the ease with which the silver dissolves. A solution assaying as high as 64 oz. silver per ton shows only a trace of gold. It is now a matter of importance to remove this silver from the solution before removing the solution from the sludge. Continued agitation of the charge would bring the coarse particles of copper to react with the silver sulphate, and in due time would precipitate the silver. But time is an object in refining, and, as this action requires more time than can be spared conveniently, it is better to use some other method for the precipitation of the silver. A small amount of hydrochloric acid, salt, or other soluble chloride may be added to precipitate the silver as a chloride, or a small amount of zinc-dust may be used. A portion of the original cupriferous sludge may be employed. Usually I set aside a small portion of the sludge, taken before the addition of the oxidizing agent, to be used as a silver precipitant.

The use of chlorides to effect the precipitation of the silver is open to the objection that a chloride, sulphuric acid, and manganese di-oxide generate chlorine, and that chlorine speedily attacks the gold. This is true except when the oxygen generated is in large excess of the chlorine, or when there are sufficient silver ions present to remove the chlorine ions thus formed. As a matter of interest it may be noted that a mixture of salt with a large excess of manganese di-oxide and sulphuric acid does not dissolve gold, but, on the contrary, is an active gold precipitant. The explanation of this apparent anomaly lies in the mutual or auto-reduction of two oxidizing agents, gold chloride on the one hand, and hydrogen peroxide or nascent oxygen on the other. Equations representing these reductions probably would be as given here. With gold chloride and hydrogen peroxide:

$$2AuCl_3 + 3H_2O_2 = 2Au + 6HCl + 3O_2$$

And in the case of atomic or nascent oxygen:

$$2AuCl_3 + 3H_2O + 3O = 2Au + 6HCl + 3O_2$$

As the object in adding the chloride is to remove the silver, and as the generous evolution of oxygen has ceased, the two safeguards against the dissolution of the gold are absent, so that extreme care should be exercised in the use of the chloride as a precipitant. It is safer practice to use a small amount of zinc-dust, or, even better, a small quantity of the cupriferous sludge.

Having precipitated the silver by some convenient method, the charge is drawn into the filter, washed, dried, and melted. Some precaution should be taken against the solution coming in contact with the iron of the press, pumps, etc., as the iron precipitates the copper, and in the course of a short time the machinery will be destroyed. Triplex pump-cylinders quickly deteriorate, and any iron parts of the stirring mechanism are soon destroyed. Lead-lined or wooden tanks should be used, and where necessary to pump the solution, lead-lined centrifugal pumps with brass runners should be used; also lead-lined pipes. For a filter we are employing a rectangular wooden vacuum-pan, 3 ft. wide by 6 ft. long, with a sludge compartment 15 inches deep and a filtrate compartment 20 in. deep. A 4 by 6-in. triplex pump serves as a vacuum-pump. This pump is attached to the filtrate compartment immediately below the filter-bed, by which arrangement it is possible to filter the sludge without drawing the filtrate into the pump. To maintain a wet vacuum the pump is allowed to draw a small amount of water from an independent source.

The filtrate assaying 0.005 oz. gold, 0.03 oz. silver per ton, and from 3 to 4% copper is treated with scrap-iron for the removal of the copper, and is discharged to waste. The filtrate compartment of the vacuum-pan contains scrap-iron upon which the copper is precipitated. The solution being hot, precipitation proceeds rapidly.

Formerly I removed the zinc sulphate solution by decantation, filtration, and washing previous to applying the copper treatment, but as the results are equally as good by treating for copper without removing the zinc sulphate, and as considerable time is saved thereby, treatment for copper follows immediately upon the acid treatment. The time consumed by this extra refining operation is from one to two hours.

A 20–30% copper sludge is reduced to 2–4% copper within a couple of hours. The bullion that formerly assayed 550–750 fine now assays better than 900. The saving in fluxes, crucibles, and time of melting is appreciable, but the greatest saving is in transportation and mint charges. Whereas formerly the mint charge on bullion containing 1000 oz. gold and silver was from $75 to 85, it is now less than $25.

To show the effect of this oxidation process on the quality of the bullion, I am here giving the assays of two bars, bar No. 25 refined in the ordinary way, and bar No. 31 refined with the aid of oxidation:

Bar No. 25		Bar No. 31	
Gold	207.35 fine	Gold	298.5 fine
Silver	561.84 "	Silver	624.5 "
Copper	22.1%	Copper	0.6%

The particular method of applying the oxidizing agent is of small consequence, since the copper is attacked with avidity. Results obtained by adding the powdered manganese di-oxide to the sludge with an excess of dilute acid are as good as when it is added to the thickened sludge from which the excess solution has been decanted, provided only that sufficient water is present to dissolve the copper sulphate formed. Good results may also be obtained by incorporating the oxidizing agent with the sludge-cake from the press and leaching it with an acid solution. The temperature should be high to accelerate the action, otherwise it works well in a cold solution. It should be borne in mind that the rapidity of the action depends also upon the fineness of the manganese di-oxide. The mineral pyrolusite is ground for commerce and sometimes contains an appreciable amount of coarse material. The dissolution of this coarse material by sulphuric acid may not take place within 24 hours. All

that is not dissolved within the time of treatment must be slagged off in the melt. If it is not decomposed in the process of drying it is available in the melt to oxidize some of the remaining copper, also some of the silver. This residual manganese di oxide makes dangerous the use of chloride for the precipitation of the silver as has been noted elsewhere. It is more quickly acted upon by hydrochloric acid than by sulphuric acid. Were there no residual oxidizing agent the chlorides could be used with impunity.

An interesting point in the process is the amount of zinc dissolved aside from that dissolved by the acid treatment. Four separate laboratory-tests showed that almost twice as much zinc was removed as copper. Some of the sludge direct from the zinc-boxes was treated for three days with several changes of acid both hot and cold, of varying concentration, and the residue washed until the wash-water showed no zinc by the ferro-cyanide test. The treatment for copper was then applied and the filtrates assayed for copper and zinc. The results are shown in the table.

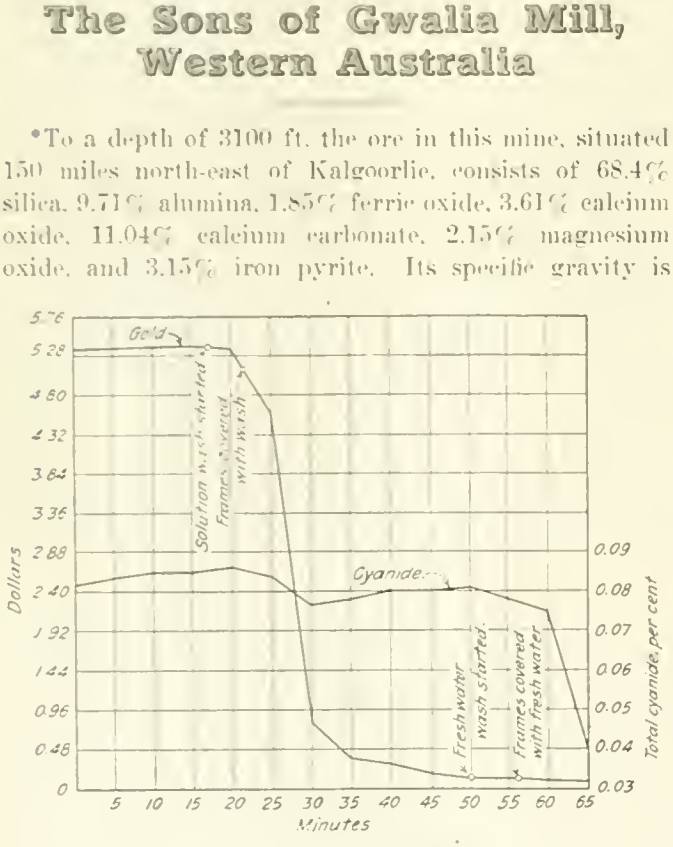
	Copper, %	Zinc, %
Test No. 1	0.86	1.15
" " 2	0.56	1.21
" " 3	1.54	3.85
" " 4	1.00	0.60

In explanation of this it might be recalled that precipitation is due to a large extent to electrolytic action and it might be that small particles of zinc are entirely coated with copper, sufficiently to prevent the contact with acid until the copper has been removed by oxidation and dissolution.

In this process the lead is not removed; the finely-divided lead is probably oxidized and then transposed to the sulphate, but the sulphate is not dissolved appreciably in the dilute acid. At the present time about 95% of the base metals in the bullion is lead.

The Sons of Gwalia Mill, Western Australia

*To a depth of 3100 ft. the ore in this mine, situated 150 miles north-east of Kalgoorlie, consists of 68.4% silica, 9.71% alumina, 1.85% ferric oxide, 3.61% calcium oxide, 11.04% calcium carbonate, 2.15% magnesium oxide, and 3.15% iron pyrite. Its specific gravity is 2.69. The gold value is $7.20 per ton, this metal being very fine, alloyed with 1/12 its weight of silver. Pyrite in schist is the richest part of the ore. Fine-grinding and amalgamation extract 85% of the gold, according to Thos. B. Stevens. When this ore is crushed a concentration of both mineral and gold takes place in the fine sandy portion. For successful cyanidation, fine crushing is essential. Sand-leaching gives a low recovery. The economical limit of grinding is 150 mesh; on the Rand, with a similar ore, this point is 90. All the Gwalia ore requires sliming, including the pyrite. The reduction plant consists of a No. 6 Gates K crusher; fifty 1150-lb. stamps with 108 drops of 7½-in. per min.; screens, with an aperture of 0.097 sq. in.; ten 5-ft. diameter grinding-pans making 60 r.p.m., fitted with Freeman pipe-classifiers, and three 4½ by 18-ft. tube-mills, working at 27 r.p.m. The intermediate accessories are a 53-ft. tailing-wheel, diaphragm-cones, and spitzkasten.



FILTER-CHART FOR SONS OF GWALIA PLANT.

From three 28 by 10½-ft. mechanical thickeners the slime goes to agitators 28 by 6½ ft., constructed from old leaching-vats, consisting of mechanically-driven arms and a distributing air-lift. Five horse-power is required and 70 cu. ft. of free air per minute. Of the total, 72.5% is extracted by cyanide, only 28.7% is dissolved in the agitators, while 19.4% is dissolved in the pans, 8% in tube-mills, 1.5% in launders, classifiers, etc., and 1.5% in the mortar-boxes.

The pulp is porous, and the vacuum-filter has a high duty. With 27-in. vacuum and 40% solid pulp, a 3-in. cake containing 28% moisture and 20.5 lb. dry slime per sq. ft. can be obtained in 20 min., while an hour is required for washing with barren solution and water. The accompanying chart shows the rate of filtration and value of solution. Cloths last six months.

Solution precipitated amounts to 1.6 tons per ton of ore treated. Zinc-shaving is used for precipitation, aided by 0.3 oz. lead acetate per ton of solution. Clean-up is done twice a month, there being nothing unusual in the method. The bullion contains 799.3 parts gold, 81 silver, 32.5 lead, 64.8 copper, 9.3 iron, and 12.1 zinc.

On an average of 13,534 tons of ore per month for six months, the cost of treatment was $1.39 per ton, divided as follows: crushing and transport 9; stamping 26; tube-mills 19; agitation and filtration 55; precipitation and melting 15 cents per ton.

*Abstract from *Monthly Journal* of the Chamber of Mines of Western Australia.

Flotation Principles

By C. Terry Durell

IN attempting to start a discussion on flotation by setting forth my osmotic hypothesis, the main objects were (1) to firmly establish fundamental laws and definitions and (2) to bring out and classify new phenomena. Flotation terms have been misused and jumbled in the same way that the so-called expert makes a mining report ridiculous by the use of geological terms. Litigation has made the subject more confusing, and it is still an indefinite cloud to most people. Now that first principles and definitions are being agreed upon, concerted effort is starting experimentation along definite lines that will lead to far-reaching results instead of the heretofore duplication of efforts leading to nothing. Before the final solution of a problem can be accomplished, the problem must be stated properly. It is therefore quite gratifying to see that the discussion is fulfilling the two main purposes and that the flotation problem now stands out more clearly.

A man can never learn from one who agrees with him entirely. For this reason I was pleased to see exceptions taken to my article 'Why Is Flotation?' O. C. Ralston thinks I used rather loosely the two words 'nascent' and 'occlusion.' It took me a long time to realize the prime essential for an effective froth. This can only be described clearly by the word 'nascent.' It also required several years of patient effort to convince myself that the whole subject depends on gas 'occlusion.'

Being unable to learn anything more in this country concerning flotation, some four years ago I made a trip to Australia, the home of flotation. There I saw for the first time copper concentrate won by flotation. At the Lake View, in the Kalgoorlie district, I saw one of the old bulk-oil flotation plants.

It was at Broken Hill, however, that I had plenty of time and opportunity to study flotation. Companies using different processes were naturally adverse to entertaining a stranger who might be gathering information to be used against them in one of the various law-suits. As soon as the managers or officials in charge were assured that I was not there for that purpose, they afforded me ample opportunity to learn everything concerning flotation, giving me access to figures and data. In this country, it is seldom that a comparative stranger receives such courteous treatment as was shown me by the cordial company officials there.

At the Proprietary mine, where the Delprat process was in operation, no oil was being used, yet there was practically the same persistent froth as at other plants using the Minerals Separation process. This fact then eliminates the two hypotheses for flotation advanced by Mr. Ralston[1], who says that "The first hypothesis is based on some academic work done by Reinders, who deduced the following inequalities as applying to a case where a powder, or the particles of a colloid, is suspended in a liquid to which is added a second liquid that is immiscible with the first." There at the Proprietary mine, where 500 tons per day was being treated by a single 'cell,' no such liquid was used. Therefore, according to Mr. Ralston's hypothesis, froth-flotation could not take place. Yet the records show that thousands of tons of zinc concentrate have been recovered by froth where no oil was used. I quite agree with Mr. Ralston when he says "It hardly needs to be said that here we find something very close to the conditions obtained in the flotation process." "In fact, the old Elmore bulk-oil flotation method fulfills exactly the conditions that Reinders had in mind." By basing the whole subject of flotation on gas occlusion, as I have done in my article, 'Why Is Flotation?' in Mining and Scientific Press of September 18, 1915, all flotation processes may readily be explained.

On seeing for the first time a single spitzkasten being fed 700 lb. of ore per minute by means of a 'push-feeder' as is done at the Proprietary, one can but marvel at the simplicity and rapidity of action of this froth-flotation process, which makes a marketable zinc concentrate with high recovery without re-treating. As no oil was used, I summed up as follows the essential elements: gas, acid, and heat, in addition to ore and water. There is nothing else essential to this treatment. Studying the conditions there, I soon became convinced that the function of the acid was not only to produce bubbles for froth-formation, but also for the creation of selective action. Since the solution was kept as near the critical temperature of 80° C. as possible, no air from the solution could aid in froth-formation because the solution was under a hydrostatic head and was admitted at the bottom of the spitzkasten instead of by means of a jet above the surface. It was easily seen that the function of gas was for froth-formation and that the persistence of the bubbles was mainly due to the enveloping net of mineral particles. What then was the function of the heat? The cold ore dropping into this hot solution carried some air with it which the heat expelled. This was not the essential factor. The heat expelled enough of the occluded gas from the ore particles to form nuclei for the attachment of nascent gas to form flotation bubbles.

Studying the Elmore vacuum process at the British

[1] 'Why Do Minerals Float?' by O. C. Ralston, *M. & S. P.*, Oct. 23, 1915.

Broken Hill plant at a later date, I summed up the essential elements there as follows: vacuum (to liberate the air), acid, oil, and alkali. At a first glance it was seen that here was another method of making bubbles and froth. This froth was perhaps more persistent, as the envelope for the bubbles seemed tougher. The difference was so slight that it is best described as that between the froth formed during the early stage of the clean up in the acid or 'cutting-down' tank of a cyanide plant and the froth formed during the later stages. It was natural, therefore, to assume that the principle or cause of this Elmore process of flotation was identical with that of the Delprat at the Proprietary. I was told there, and have been repeatedly told since, that the oil was the cause of the selective action. I never will believe this, with all the evidence against it, although on account of adsorption—not occlusion—of gases by the ore particles, they are more easily wetted with oil than with water. The results at these two mines were practically the same. The grade of the concentrate at the British plant was higher, by reason of mechanical refinements, and not the difference in process. Therefore the oil could not be the essential element for selective action, because no oil was used at the Proprietary. The oil was an essential element only in that it toughened the froth. Owing to mechanical means of operation, the froth could not be removed so quickly nor could it be carried in such a deep layer. Therefore oil was added to toughen it. Using Mr. Scott's words[2], "This froth rises and floats much the same as a board would" while the Delprat bubbles "float over, if we get them over before they break"; and "if they do break, the mineral drops and is caught by the bubbles below." Oil, then, can be eliminated in making the following comparison between the essential elements of these two processes. Acid creates the selective action as in the Delprat method; lime is then added to neutralize it, because the vacuum machines are of cast-iron. Acid was found to be necessary in the Delprat process to create the bubbles. It was necessary for these bubbles to form as they "came into being" on mineral particles as nuclei. Nascent bubbles of air are formed in the same way, so that the vacuum of the Elmore process takes the place of the acid in the Delprat.

At the British plant, in making a froth, the solutions were not heated, for the reason that the vacuum which drew the dissolved air from the liquid, in accordance with the law of Henry, also drew a sufficiency of occluded air from the mineral particles to form nuclei for the air "coming into being" from the liquid. The acid had already acted as previously described. The small slow-speed mixer, just ahead of the vacuum machines, used for stirring oil into the thickened pulp, could in no way super-saturate the mass with air as is the case with a Minerals Separation machine, which process will be taken up later.

When I began the study of the De Bavay process at the Amalgamated Zinc plant, I was at a loss, at first, to see how the same principles underlying the other two processes just mentioned could apply there. The following essential elements were separated out: gas (in the form of air), acid, and oil. Mr. Meredith told me the object of the acid was to clean the mineral particles. While it undoubtedly does this, my contention is that it acts as an electrolyte, as I have described, to create the selective action afterward manifest during the oiling and aerating stages of the process.

Oiling of the mineral particles is the next stage and can only take place in liquid pulp, as I have explained, when particles themselves contain gas. It required a careful study of the apparatus at the Amalgamated plant before I was able to understand that the same underlying principles applied here. Air was necessary; yet where and how was it introduced? This is best described in T. J. Hoover's[3] words: "Throughout this manipulation, including the acid-washing, the oiling, the raising with compressed air, and the flowing over the corrugated cone, the sulphide particles are repeatedly aerated, and as a result, especially after the oiling, take up their adhesive air-films and float." They were not using corrugated cones when I was there. Instead, the cones were covered with concentric rows of staggered triangular obstructions. These were made by bending the triangular burrs from holes punched in galvanized sheet-iron cones until they were perpendicular to the surface. These cones were then fitted down tightly over similar cones not punched. A montejus was used to lift the prepared pulp to these cones. As Mr. Hoover says, "The subjecting of the oil pulp to compressed air may be an essential part of the operation." It undoubtedly is, and this method is patented by Dudley H. Norris,[4] although opposed by Minerals Separation Ltd. when application for patent was made in England.

The De Bavay float is caused by air. Why is it not a froth? Norris turns his super-saturated liquid directly into the pulp-mass and a froth is formed. The pulp-mass at the Amalgamated Zinc plant, super-saturated with air, was turned on to the top one of each series of four cones. There was no chance for froth to form while spreading in a thin stream over the surface of a cone. This float, however, is entirely different from the unstable float on the Henry Wood type of machine, which depends on surface tension entirely. It is best described in the words quoted from De Bavay: "When the contents of the receptacle were emptied into a beaker, a thick clean layer of 'black-jack' sprang to the surface of the liquid, while the white clean gangue was precipitated to the bottom."[5]

Upon studying several plants using the Minerals Separation process, the following essential elements of flota-

tion were easily recognizable: air (beat in by stirrers to super-saturation), acid, oil, and heat.

It is to be noted that these are the same as described in the other processes. Practically the only difference is that the froth is more persistent, because there is more slime with which to armor the bubbles. The violent agitation coagulates the exceedingly fine metallic particles in the same way that butter forms in a churn. These coagules are then taken up in the froth the same as larger metallic particles. As Mr. Hoover[6] states, "Large quantities of air are beaten into the pulp. By running the machine for a few minutes on water alone, it will be observed that the quantity of air so beaten into the pulp is enormous, for the clean water will be milk-white." This air, as it "comes into being," uses the mineral particles as nuclei from which to grow into bubbles.

The résumé of these commercial processes is to show that nascent gas is necessary. The only explanation of single selective action for all processes is that gas is held in the solid particles.

A theory that will not explain all of these processes is of no value whatever. Both of Mr. Ralston's hypotheses depend upon the use of oil, which is not an essential element to flotation, as was shown above. Also these hypotheses assume that bubbles, existing as such in a liquid pulp, can then have mineral particles attached to them. If this be so, and it is not necessary to grow, as it were, the bubbles from the nascent gas in the liquid, why is it necessary to beat air into solution beyond the saturation point as is done in all froth-flotation machines using air as an adjunct except in the Callow machine? It would be much simpler to turn in a stream from a compressor or blower. If electrification is then all that is needed to produce attachment of the mineral particles, surely there are plenty of ways to electrify the bubbles. Thomas M. Bains[7] says, "It would seem easier, therefore, to electrify a bubble than to keep it from being electrified." No; something more than electrification is required of the bubble, as all who have tried to produce a float in this manner well know. James A. Block,[12] in his criticism on my article says: "I cannot see how the water in a Callow or other pneumatic machine can become greatly super-saturated." This is best answered by Mr. Callow[8] himself: "The bubbles composing the froth are generated under a hydraulic pressure varying from 15 to 40 in." It matters not whether the water be saturated "with air at a pressure of several atmospheres," as was done by Norris, or under a hydraulic pressure of 15 inches, because, as I pointed out, it is not the air that is held dissolved, but it is the air that comes out, which is available for mineral attachment. A hypothesis based on nascent and occluded gas explains all kinds of flotation as well as all flotation machines.

More flotation experiments have been carried out in Australia than in any other country. No publication of systematic experiments to learn the reasons for flotation is so complete as that in the proceedings of the Royal Society of Victoria, by Kenneth A. Mickle.[9] His experiments (many of which I have verified in the laboratories of the Colorado School of Mines while experimenting in the new testing plant there some three years ago with the Horwood process) showed nascent gas necessary and also that the particles must contain gas. He showed by experiments that (1) heat or reduction of pressure to liberate gas, that (2) generation of gas by means of acid, or that (3) super-saturation of solutions with gas, will cause minerals to float or tend to float without the aid of oil. He showed the effect of gases occluded by minerals to be (1) the particles are not wholly wetted when immersed in water; (2) the particles tend to float when sprinkled on water; (3) the particles when immersed collect bubbles as the solution is heated or exposed to vacuum and float or tend to float; and (4) the particles in gas-saturated solutions collect the bubbles evolved. He says, "In my earlier paper, it was shown that mineral particles absorb gases to an extent not previously suspected and that they retain the gas adsorptions with such persistency that they could neither be easily separated by mechanical means nor much affected by gravity and gas expansion." He also says, "In previous investigations, I found that carbon dioxide was obtained from all sulphides by the aid of heat and exhaustion in the presence of water. It is probable that the gas film can be expanded for removal in appreciable quantities only in the presence of water and that exhaustion in the dry state does not remove all the gas present."

With a view to further investigating the gas held by solids, he conducted the following experiments:

1. Copper and silver foil were cleaned with sodium hydrate and distilled water and dried. These and uncleaned pieces were treated in a vacuum-flask. Few bubbles formed on cleaned foil with distilled and air-free distilled water, but more on the uncleaned. All foil floated in tap-water.

2. Six steel needles were cleaned in the same way as the foil and allowed to stand one half-hour in alcohol and then dried in a desiccator. They would not float on distilled water until it had been exposed for some time to the air. Another set of needles and iron wire were similarly cleaned, but would not float until allowed to stand in a desiccator for two days. The same results were obtained with sulphides cleaned with sulphuric acid.

"These experiments show that perfectly cleaned needles and iron wire will float on the surface under the following conditions: (a) if the water is allowed to stand for some time in contact with the air; (b) if the needles and wire are allowed to remain exposed to the air for sufficient time."

[9] Vol. XXIII and XXIV (N. S.) Part 2, 1911. Abstracted in *Eng. & Min. Jour.*, p. 307, Aug. 12, 1911 (vol. 92), and p. 71, July 13, 1912 (vol. 94).

3. Cleaned and uncleaned pieces of iron wire, on being immersed in a saturated solution of carbon dioxide showed the following results: (a) clean pieces collected very few bubbles, while (b) uncleaned pieces were covered with a frost of bubbles.

I have confirmed these experiments, therefore I am positive of the incorrectness of Mr. Rickard's statement, "If you place an ordinary needle, say, a lace needle suitable for use with No. 80 thread on the surface of a bowl of water, it sinks at once to the bottom, in obedience to the law of gravity. If, however, you pass the needle through your hair, so that it becomes greased, it will float on the water."[10] This is the same old false assumption that oil is a necessity instead of an aid to flotation.

Swinburne and Rudorf[11] say, "A way of demonstrating the presence of gaseous envelopes is to sift some powdered substance which easily sinks, such as sand or ferrous sulphides, upon the surface of hot water, previously freed from gas by boiling. Bubbles of gas rise from the surface of solid particles." "It seems necessary that the gas should be produced at the surface of the particles themselves." "The air-film always plays an important part; and if the ore is thoroughly washed or boiled in water to remove the air-film, it cannot be concentrated with acid."

There are many other references all showing the same thing: that the mineral particles to be floated must contain gas so as to act as nuclei for the gas as it "comes into being" from the liquid. Therefore, in my former article, I did not present this evidence to prove my statement, which seemed a self-evident fact in view of the present knowledge of the subject.

Mickle collected gases from concentrate made from Broken Hill material some of which gas contained:

(1)		(2)	
N	72%	N	82%
O	2	O	2
CO_2	26	CO_2	16

It is seen that these gases obey Henry's law, each existing independent of the others and not displacing the others as Mr. Block[12] says undoubtedly would be the case. An analysis of a sample from the Horwood process gave:

N	95%
O	1
CO_2	4

These three samples of gas became disengaged from three samples of concentrate which were allowed to stand. Afterward a vacuum applied to No. 1 sample (70 gm. sulphide) gave a further amount of 1.7 c.c. gas analyzing:

N	27%
O	14.1
CO_2	58.8

On raising the temperature to the boiling point and subjecting this sample to vacuum, there was then given off 8.9 c.c. of gas, which was found to be practically all carbon dioxide.

From the No. 2 sample he obtained 18.5 c.c. gas of which practically all was CO_2. On subjecting minerals to reduced pressure and heat, he found that he could obtain more gas from calcite and quartz. This was mostly CO_2. He proved in all these cases that the CO_2 obtained was not from the decomposition of carbonates. This shows that minerals in general occlude gas, although Mr. Ralston[1] says that "good cases of occlusion have been found thus far only in amorphous substances." Mr. Block is quite right when he says: "that it would be liberated with sufficient rapidity to float the particles does not seem probable."[12] Also Mr. Ralston[1] is correct in saying "How the tightly-held gas could be liberated fast enough to compare with the exceedingly short time which it takes to accomplish flotation of a sulphide particle is difficult to explain physically." I simply stated that "if this gas be expelled from them, when they are in a liquid, at a time when the gas is expelled from the liquid, they become the nuclei for the formation of gas bubbles." On the other hand, if bubbles are not formed from nascent gas of the liquid in contact with the mineral particle there can be no adhesion because the bubbles are surrounded by liquid films; or, if the particles contain no occluded gas, there can be no adhesion because the particles are surrounded by liquid films.

That these two words 'nascent' and 'occlusion' were objected to shows the necessity of extreme care in the choice of terms, and I am glad that Mr. Ralston brought up this point. 'Nascent' is defined in Webster's New International dictionary (3rd), 1915, as follows: "Being born; coming into existence; beginning to grow; commencing, or in process of, development." The Century dictionary, 5th edition, 1911, gives practically the same definition as follows: "Beginning to exist or to grow; commencing development; coming into being; incipient." The following usage is given: "Wiping away the nascent moisture from my brow: Barham, 'Ingoldsby Legends'." Available gas of any kind for flotation must "come into being" in this way. Mr. Bains[13] excellently describes this, as follows: "If powdered galena ore, with a limestone gangue, be dropped into pure water, most of the powder will immediately sink to the bottom. As the air enclosed by the particles is expelled gradually, one sees the formation of 'armored' bubbles, some of which may last for days. Here is flotation without oil or acid. If nitric acid be added, the gas bubbles formed by the action of the acid on the gangue, will carry up particles of galena." I have placed ½-inch pieces of quartz, galena, and other minerals in a beaker filled with water saturated with air at atmospheric pressure. The purpose was to watch the formation of the

bubbles. More small bubbles formed on the metallic minerals when heat was applied. The bubbles formed on all minerals apparently in the same way that moisture forms on one's brow. I wish to describe this. There is only one single word in the English language that can be used to do it—'nascent.' This is not "the dissolved gas that can be liberated," but it is the dissolved gas at the instant of liberation.

Regarding occlusion, Mr. Ralston has been kind enough to mention three ways by which gases can be held in solids, and I should have used more care in the choice of these terms. I used the word 'occluded' as a general term to denote either surface adsorption or solid solution. As Mr. Ralston says, "this is a term the meaning of which has been much disputed." Trying to show that the gas in the mineral obeys the same laws as the gas in the liquid, as proved by Mickle, I spoke of the gas being dissolved in the solid and thus led up to the term 'occlusion,' having in mind the following: "The amount of gas which dissolves in a given quantity of water is proportional to the pressure, and from this experimental result, Van't Hoff showed mathematically by the principle of thermo-dynamics that, when in solution, this same gas must exert an osmotic pressure";[14] and that "Substances dissolved by solids have an osmotic pressure as shown by Van't Hoff, so we can speak of solid solutions";[15] also that "the greater the pressure to which the gas is subjected, the larger the quantity which will be adsorbed by the solid."[16]

Viscosity is another word that has been incorrectly used in connection with flotation. Mr. Rickard[10] in his article, 'What is Flotation?' states: "The combination of low tension and high viscosity enables a bubble of gas, rising through the liquid, to lift the surface film of the liquid, which the tension of the bubble-film is not strong enough to break, so the bubble endures"; and cites 'A Text Book of the Principles of Physics,' by Alfred Danniell, 1911. Also Mr. Rickard states: "Pure water has great surface tension, it also has no superficial viscosity."

Viscosity as known today is an entirely different property of matter from that which Danniell in 1885 confused with surface tension.

Perhaps the best definition of viscosity is by Harry C. Jones,[17] as follows: "We need simply mention here the works of Poisenille, Pagliani and Battelli, Slotte, Gartenmeister, and Traube" * * * "The monumental works of Thorpe & Rodger merit more careful attention." * * * "They prove conclusively, what has been hinted at before, that * * * viscosity may be taken as the sum of the attractive forces in play between the molecules; * * * It is, therefore, made evident that viscosity or inter-molecular attraction is in reality a property of the atoms of which the molecules are composed." This 'superficial viscosity' is well explained in the Encyclopedia Britannica,[18] as follows: "The varying of contamination to which a water surface is subject are the causes of many curious phenomena. Among these is the 'superficial viscosity' of Plateau." * * * "Plateau attributes these differences to a special quality of the liquids named by him 'superficial viscosity.' It has been proved, however, that the question is one of contamination and that a water surface may be prepared so as to behave in the same manner as alcohol." Mr. Rickard, in his second article, page 517, Mining and Scientific Press, October 2, 1915, says: "To make bubbles, the surface tension of water in the flotation-cell must be decreased by a contaminant and at the same time the viscosity of the liquid must be strengthened." As shown above, it is not the viscosity but the general surface tension effect that must be strengthened. As I pointed out, a soluble or partly soluble oil will decrease the surface tension of water because it dilutes the water, which has the greater surface tension. By reason of this cause alone, the tendency to float is decreased and the bubbles burst more easily. Using a volatile oil in a M. S. machine, I have had the bubbles burst so violently that the cement floor was blackened with zinc sulphide at a distance of several feet from the machine. At the same time I was making a very clean zinc concentrate from Leadville mixed sulphides after a Horwood roast. As no other contaminant was used, this was only made possible by having the mineral particles well oiled with the thinnest possible film to aid cohesion in armoring the bubbles well with the zinc sulphide particles. In this case the surface tension was still further reduced by the sulphuric-acid electrolyte.

Most oils, however, aid modern flotation in three ways, as I tried to point out in my former article, by (1) decreasing the force of adhesion of water for mineral particles by forming films around them, (2) increasing the cohesive force of the mineral particles for each other to aid in the formation of a network of mineral particles around the bubbles to toughen them, and (3) toughening the bubbles by forming films of oil around the bubbles in addition to those of the water. 'Toughen' is not a good word whereby to express the meaning. Mr. Ralston explains this very well and at length on page 624, Mining and Scientific Press of October 23, 1915, under his inter-facial tension hypothesis. He claims, however, "It is doubtful if the air bubbles could be completely mantled by oil." This is contrary to the experience of others. The colors on the bubbles indicate that they are mantled." This shows that Mr. Callow is right when he says "The bubble-mantles in a flotation-machine are undoubtedly composed of oil, or oil emulsion."[19] The sum of these tension effects cause persistent bubbles, even though the surface tension of the water has been reduced. These undoubtedly are ex-

tremely thin films, at least approaching one molecule in thickness.

Therefore molecular forces must be taken into account in dealing with them; as Mr. Ralston says, "The underlying cause of the tensions and of electric charges is the same thing—some strange molecular, atomic, or other force manifested in 'adhesion,' 'cohesion,' or even 'gravitation,' if you please." In dealing with these interfacial tensions, the drop-weight method cited by Mr. Coghill[20] for determining surface tension is of no value to flotation.

The interfacial hypothesis of Mr. Ralston explains very well indeed the persistency of bubbles, but I am not so easily satisfied as is Mr. Block,[12] who says, "T. J. Hoover, for instance, in his book, 'Concentrating Ores by Flotation,' presents a consistent theory." Mr. Hoover (2nd edition, page 72) says: "There has been no satisfactory theory yet propounded as to why acid does promote the preferential adhesion of water to gangue particles." Even the late electrical theory fails to answer all the questions asked by Mr. Hoover, on page 100 of his book. I answered the above question in my article by showing that an acid or any electrolyte creates osmotic pressure, by trying to enter the solid particles, of which their surfaces act as septums. If this pressure be sufficient to drive most of the gas out from the gangue particles, the metallic particles can be floated, for the reason that there is still left sufficient gas in them to become nuclei for bubble formation by the nascent gas of the liquid.

As shown by Mickle's experiments, mentioned above, there is more gas in sulphides than in other minerals and it is held more persistently in the sulphides. Thus a selective flotation is created. I have confirmed these tests.

Everyone who has experimented with flotation has seen how too much acid will 'kill' the float. That is, the greater osmotic pressure drives the air from the metallic particles as well as from the gangue particles.

This effect is not to be confused with that caused by substances such as tannin or saponin mentioned by Mr. Callow[19] as colloidal impurities or volatile oils and the like, which destroy bubbles by reducing the surface tension to the extent that the gas pressure from within breaks or even explodes them. This weakening of the surface tension by a colloid is an entirely different phenomenon from that shown when the osmotic pressure is increased by a crystalloid.

"The crystalloids when dissolved in water change in a marked degree its properties; for example, they diminish the vapor pressure, lower the freezing point, and reduce the boiling point."[21]

And as Dr. Lupke[22] states, the four laws in speaking of dilute solutions, are "Equimolecular solutions of any substances, prepared by using equal weights of the same solvent, exhibit equal osmotic pressure, equal relative depressions of vapour pressure, equal risings of boiling point, and equal lowerings of freezing point."

In maintaining that osmotic pressure of an electrolyte is the cause of selective flotation, it is well to look into the motive power of osmosis. Kahlenberg[23] states it "lies in the specific attractions or affinities between the liquids used and also between the latter and the septum employed. These affinities have also at times been termed the potential energy of solution, etc.; they are, to my mind, essentially the same as what is termed 'chemical affinity'." Or, as F. H. Garrison[24] put Taube's theory: "The driving force in osmosis is a superficial (or interfacial) pressure obtained by subtracting the surface tension of one fluid from the tension of the fluid into which it diffuses." Or again as Van't Hoff and his followers contend "The molecules of a dissolved substance exert the same pressure against a semi-permeable membrane, during osmotic processes, as they would exert against the walls of an ordinary vessel were they in the gaseous state at the same temperature and the same concentration."[22] Since these authorities do not agree on the motive force of osmosis, investigation must rest for want of further data.

However, all theories of flotation, be they electrical or otherwise, must come to osmosis for their solution. This is not to question the fact shown by electrolysis that every atom of matter is capable of uniting with a definite quantity of electricity. Nor is it to question that corpuscles (later termed electrons by Dr. Stoney) do not revolve around atoms which are thousands of times larger. But it is to question any hypothesis that does not take into account the fact that particles will not float when all the gas is driven from them. Osmotic pressure can free particles of their occluded gas. Whether osmosis is caused by electricity or whether a current of electricity is caused by osmosis has no bearing on flotation. However, in passing, it may be of interest to mention that Dr. Robert Lupke, in his book 'Elements of Electro-Chemistry' devotes Part III to 'The Osmotic Theory of the Current of Galvanic Cells.'

As mentioned above, extreme dilution of the electrolyte affects the osmotic pressure and selective flotation. With complete dissociation, as Arrhenius has shown, the ionized molecules are free to obey electric forces. It may be freely granted that air driven from a particle by osmosis may effect a change in the 'contact-film' mentioned by Mr. Callow and leave the particle negatively charged, so that it would sink as described by him. Also it is granted that the mineral particles are all either negatively or positively (?) charged. Assuming the electric charges, there then enters the important question mentioned by Mr. Callow in stating his theory that "the

[24] 'A Note on the Tauhe's Theory of Osmosis and Attraction Pressure,' by F. H. Garrison, Army Medical Museum, *Science*, vol. 32, 1910, page 283.

particles possessing them will migrate when placed in an electric field." There is no question but that with an electric field, flotation can be produced in such a manner as described by Bothe Schwerin in his 'Electro-Osmotic Process'[25] as follows: "My invention consists of adding electrolytes to the liquids containing the substances to be separated, the nature of the electrolyte depending upon the character of the substance. If the latter is of such a character that they would be deposited by the electric current on the cathode, electrolytes of acid character are employed; and if the substances would be deposited on the anode, electrolytes of basic character are used." Speaking of finely-divided substances, sometimes indifferent to the action of an electric current, he continues: "I have found that such substances can be made electrically active by causing them to adsorb [here used as defined by Mr. Ralston] colloidal substances of a strong electro-positive or electro-negative character." Of the recent electrical theories advanced, none explains how this important electrical field, mentioned as necessary by Mr. Callow, is created by any flotation machine. Mr. Block[26] shows this on a clay machine.

After selective flotation is created by osmosis, it matters not whether the particles be spoken of as being held together or to the bubbles by electric charges or by cohesion and adhesion in the way I mentioned. Sir Oliver Lodge,[27] after saying that "the force of chemical affinity has long been known to be electrical" goes on to say that "there is another kind of adhesion or cohesion of molecules, not chemical, but what is called molecular. This occurs between atoms not possessing ionic or extra charges, but each quite neutral, consisting of paired-off groups of electrons." However great this attraction may be, the mineral particles will not adhere to bubbles already formed, as was shown above; but, using them as nuclei, the nascent gas will form into bubbles to float them. Such gas formation is excellently described by Duhem[28] as follows: "From this, a bubble of vapor will never be formed in a region where the liquid is continuous; in fact, if such a bubble could begin to form, its radius would be at first infinitely small—less than the limiting radius of which we have spoken; whence, instead of continuing to grow, it would collapse." On the next page he continues: "These considerations do not apply merely to boiling; they completely explain a great number of phenomena."

The electrically-charged mineral particles may aid in bubble formation although they cannot effect attachment of mineral particles to bubbles already formed. Regarding this, Dr. Thompson[29] says that "the charged particles act as nuclei around which small drops of water condense, when the particles are surrounded by damp air cooled below the saturation point." "Experiments were made with air, hydrogen, and carbonic acid and it was found that the ions had the same charge in all the gases." Also, "Thus by suitably choosing the supersaturation, we can get the cloud deposited on the negative ions alone so that each drop in the cloud is negatively charged." Electricity may manifest itself in various ways, but flotation cannot take place without nascent or occluded gas.

Accident Compensation

California, like several other states, has had a workmen's compensation law for about two years. The law in this State provides that liability for compensation shall exist against an employer for any injury received by workmen without regard to negligence, providing the accident is not due to intoxication or wilful misconduct. Compensation is usually on a basis of 65% of the wages of the workman. The measure was opposed by employers, particularly by the gold-mine operators who contended that, unlike other lines of industry, they could not add the cost of their insurance directly to the selling price of their product.

The report of the Industrial Accident Commission for the last fiscal year indicates that a total of 6858 employers had accepted the compensation provisions of the law. A change of sentiment is apparent, as the employers realize the benefits of the system.

An important decision was rendered in the case of the appeal of the Great Western Power Company against the decision of the Industrial Accident Commission. It was held that James Mayfield met his death as a result of wilful misconduct and the court laid down this rule: "it cannot be doubted that a workman who violates a reasonable rule made for his own protection from serious bodily injury or death is guilty of misconduct and that where the workman deliberately violates the rule, with knowledge of its existence and of the dangers accompanying its violation, he is guilty of wilful misconduct."

The success of the State Compensation Insurance Fund has been noteworthy. At the close of the first year, 1914, the fund had written $547,161 in net compensation insurance premiums, approximately $144,000 in excess of the writings of its nearest competitor. A refund to policy-holders of 15% of earned premiums was allowed as policies expired and actual payroll expenditures of insured employers were ascertained. The total amount of this refund was approximately $75,000. It is estimated that an additional refund of 28% will be returned to policy-holders, or a total dividend of 43%. At the end of the first year (1914) the rate schedule was readjusted, resulting in an average reduction of 10%.

The Industrial Accident Commission of California has issued a pamphlet of 'Mine Safety Rules' effective January 1, 1916.

Mining in Utah

By L. O. Howard

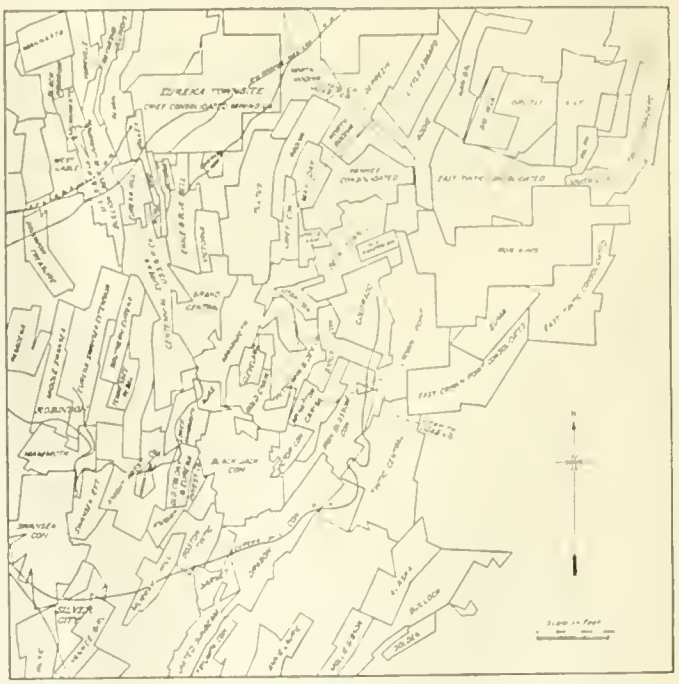
MINING has been conducted under unusual difficulties during the past month, a heavy snow-fall hampering operations in districts formerly free from serious interruption to traffic. At Park City the hauling of ore has been suspended several times. Slides have blocked roadways and damaged surface equipment. The train service from Salt Lake has been intermittent. Railroad transportation in the Tintic district has been suspended for days at a time, tending to keep shipments down. In Beaver county prospecting has been difficult, and activity diminished. Even in the desert country in Grand, Emery, and San Juan counties there has been a heavy fall of snow. Coal shipments from the eastern part of the State have been infrequent, owing to the congestion of freight at Soldier Summit. The Cottonwoods have been inaccessible at times. Slides began to run early in numerous places that have formerly been immune. Big Cottonwood was blocked to ore-teams during the first week of February and at this time of writing no ore is coming out. In Little Cottonwood occasional shipments are being made. The Maxfield in Big Cottonwood has been flooded for the second time this year, owing to the loss of power. This time a slide took out the line. A new line is being run up the canyon, so as to ensure continuous service.

Increasing metal prices continue to favor a rise of wages in the three principal districts, where most of the companies have adopted a sliding scale that enables employees to share the good fortune of the operators. Seven thousand men will be affected and about $600,000 added to the pay-roll.

Park City shipments fell from 9746 tons in December to 7370 tons in January, the Silver King Coalition, Daly-Judge, Daly West, Ontario, Silver King Consolidated, and Naildriver contributing. The Three Kings Silver continues driving in an effort to cut the fissures known in adjoining properties. It is reported that the Silver King Consolidated will drive a 14,000-ft. adit, erect a 100-ton mill, and build an aerial tramway. The mill-site chosen is at the mouth of Thaynes canyon. The Ontario is well up in the shipping list, being in third place. This mine was idle for many years.

At Bingham the recently consolidated Utah Metals-Bingham New Haven properties are producing 400 tons of silver-lead ore per day, and must henceforth be counted among Bingham's big mines. The Utah-Apex, which paid its first dividend last year, is producing 100,000 lb. of lead monthly and the profit for January reached $70,000. The company has an efficient mill combining gravity concentration with flotation. Utah Copper has announced its production for December as 14,497,485 lb. of copper, compared with 6,795,567 lb. a year ago, bringing the total for 1915 to 156,207,568, against 121,779,716 in 1914. Since May, production has been at the rate of 176,000,000 lb. annually.

The Tintic district is witnessing a revival; several old and new properties are being developed. Shipments average 100 to 120 cars per week, or 25,000 tons per month. The ore is of four kinds, lead sulphide, silver-lead carbonates, zinc carbonate, and copper-silver ore.



THE MINES OF TINTIC.

Regular shippers include, in order of tonnage, Chief Consolidated, Iron Blossom, Centennial-Eureka, Mammoth, Grand Central, Eagle & Blue Bell, Dragon Consolidated, Beck Tunnel, Colorado, Gemini, East Tintic, Bullion Beck, Lower Mammoth, Victoria, May Day, Carisa lease, Uncle Sam, and Ridge & Valley. In the eastern part of the district, the Tintic Central and the Tintic Standard are developing; the Crown Point, East Crown Point, Utah Con., Iron King, and United Tintic are planning extended exploration. The Gold Chain, Scranton, Diamond Queen, and Golden Sunset are also being worked. The Utah Minerals Concentrating Co. is treating low-grade ore from the Bullion Beck, Chief Con., and the May Day dump, the latter averaging $4 to $5 per ton. Some of this tailing has had two previous treatments. The mill is also treating tungsten ore from California, Nevada, and Utah, and is in the market for ore as low as 2%.

Deep Creek is attracting attention as a producer of tungsten. It is reported that 8000 lb. of 72% ore has

been shipped by parcel-post. The district has a number of developed properties, with large low-grade deposits of lead, silver, and copper, but lack of transportation keeps it from realizing its possibilities. Occasional shipments of high-grade ore are made.

From the district about Lucin, in the north-west of the State, shipments of low-grade tungsten ore are reported.

In the West Tintic district, between Tintic and Deep Creek, there is renewed activity. The O. K., Scotia, and Sharp properties are attracting favorable notice. They, too, are handicapped by poor transportation facilities. The Scotia is expected soon to ship a car of ore per day. It is held under bond and lease by the Chief Consolidated, now the leading producer of the Tintic district.

With the payment of another dividend early in February, the record of the Lake View at Promontory reaches $75,000; it is a property that was unknown a year ago.

Several districts in Beaver county are active. In the Star district, the Cedar-Talisman has realized enough on shipments of zinc ore to pay off all indebtedness, install electrical equipment, and accumulate a large reserve. The Moscow, another shipper, is sinking to 1000 ft., after completing the installation of an electric hoist. Among the other companies developing are the Monzonite, Cedar Extension, Paloma, Silver Gulch, Majestic, Leonora, Wild Bill, Rough Rider, Red Warrior, and Salt Lake groups. In the Lincoln district, the Creole and Croff are now well equipped, and ready to begin shipments. In the new Fortuna-Sheep Rock district, development is in strong hands. The U. S. S. R. & M. Co. is working its property, and occasional discoveries of high-grade ore are reported from neighboring leases. Other properties being developed in the Sheep Rock end of the district are the Beaver Butte, Keystone, Gold Hill, Beaver Gold, and Rob Roy. At Fortuna work is being done on the Gold Queen Fraction, Mohawk, and Copper Granite.

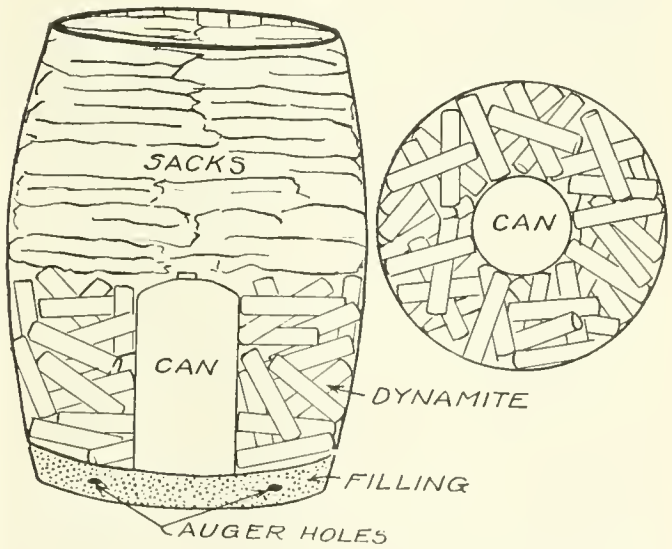
The War has resulted in direct benefit to another Utah industry, the mining of ozokerite, commonly called 'mineral wax.' Only two districts where ozokerite may be mined are known. That of Boryslaw in Galicia ceased to produce on the outbreak of the War, leaving the market to the Utah district about Colton and Summit in Utah county. The price has risen from 15 to 45 cents per pound. Two years of experimental work have resulted in the perfection of a simple process for extracting the ozokerite, former difficulties in profitable operation being due to the unsatisfactory methods used. A mill has been assembled and will be shipped to the Soldier Summit property of the Wasatch Ozokerite Co. Production is to start on a large scale early in spring. It is expected that other properties in the same belt will be exploited.

GOLD PRODUCTION of India in 1915 totaled 602,359 oz., the largest since 1905, and compared with 602,006 oz. in 1914, 589,353 oz. in 1913, 584,838 oz. in 1912, and 573,525 oz. in 1911. Most of the yield is from the Kolar field of the State of Mysore. December outputs were as follows:

Mine.	Tons.	Ounces.
Balaghat	3,002	1,992
Champion Reef	17,366	10,835
Anantapur	2,900	797
Mysore	26,500	20,609
North Anantapur	2,600	1,066
Nundydroog	8,000	7,260
Ooregum	12,850	8,100

A Simple Dynamite-Thawer

The following convenient method of thawing dynamite was written by J. H. Carse from the experience of ten years in thawing frozen dynamite. The excerpt is from the *Du Pont Magazine*. Take an old barrel, bore one or two ½-inch holes in the bottom, place a little straw, hay, sawdust, or anything that will allow water to filter through easily, to a depth of about two or three inches. Secure an old oil-can, capable of holding at least five gallons, fill this can with boiling water and place it in the centre of the barrel on top of the filling. The purpose of the half-inch auger-holes in the bottom of the barrel is to allow any water to drain out that might



accidentally be spilled. In filling the can with boiling water, it is a good plan to leave an air-space of about two inches for the steam that will arise. In case the weather is not very cold, the can of hot water should be wrapped in a sack to prevent the dynamite from coming in direct contact with it. Place the dynamite around the can in such a manner that the heat will circulate about the cartridges; fill the rest of the barrel with sacks, or anything convenient to retain the heat. If the weather is exceedingly cold, sink the barrel in the ground. In this way the dynamite will keep thawed for at least 48 hours. A 5-gal. can of boiling water is sufficient to thaw at least 50 pounds of dynamite. This plan of thawing has proved safe, for the reason that it requires 356° F. to explode pure nitroglycerine, while by this method it is impossible for the heat to exceed 212° F. Tests that have been made have shown the highest temperature in the barrel not to exceed 80 degrees.

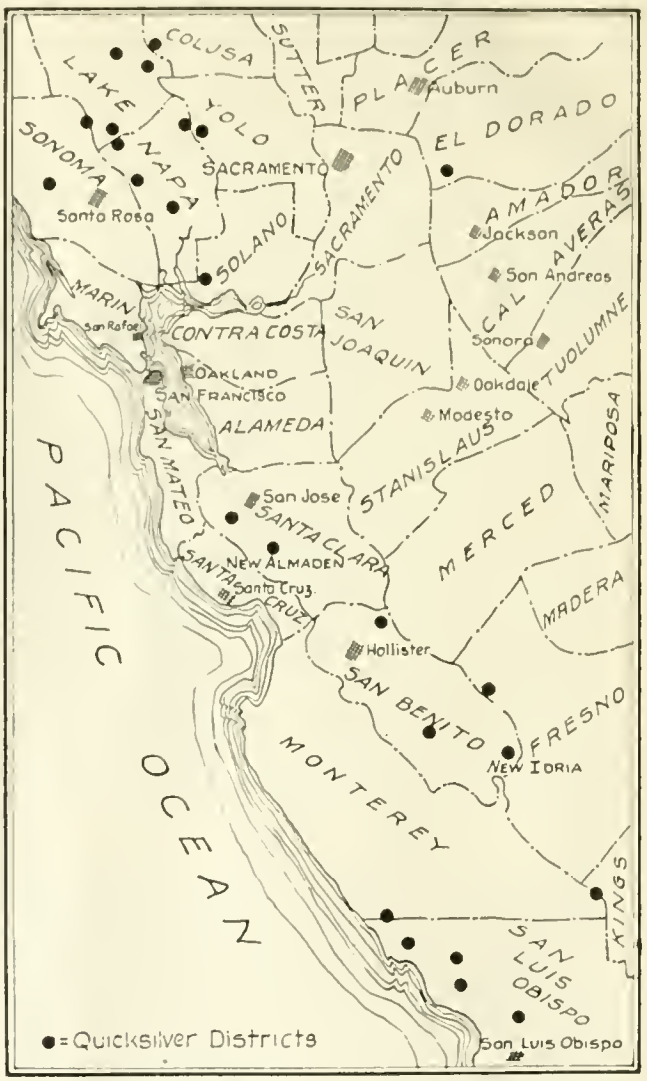
Quicksilver Mining in California

By W. H. Landers

THE high price for quicksilver, at present something over $300 per flask, has drawn attention to its production. So much has been written on the occurrence and geology of the quicksilver deposits of the United States that it seems a waste of good time to discuss the geologic features. Suffice it to say that cinnabar, the principal ore of mercury, is found as a rule at or near the contact of sandstone or serpentine, the most notable deposits in the United States being in the Coast range of California. Cinnabar ores are distributed far more widely than is generally supposed; but the low price in recent years naturally has removed the stimulus to prospecting. This explains the decline in the American production. Present prices have caused a renewal of activity in mining, and it is my belief that they will never reach as low a level as that obtaining before the War checked the importation of this metal into the United States.

The mining of quicksilver ore does not differ materially from that of any other contact deposit. Much the same conditions of hard and soft rock are offered and the same questions arise as to handling of water, the timbering of the drifts and stopes, the economic breaking, and the transportation of the product.

Cinnabar ore is generally rated in terms of mercury percentage, and this in itself is not calculated to excite interest as much as if the value were quoted in terms of dollars and cents per ton of ore. Statistics indicate that the average ore mined in California for the last three or four years contains 0.6% mercury. It is quite true that such ore may be considered low-grade in comparison with that formerly mined or from a money standpoint, 0.6% just prior to the outbreak of the War being worth only $6 per ton. However, the present price of $300 per flask means that the same yield is now worth $48 per ton. Compare this with the value of a comparatively rich gold mine, and the reason for the present public interest is evident. It is surprising what a number of promising surface showings of cinnabar ore exist in certain districts, and more surprising still that after a year of high prices, most of them remain undeveloped. It is hard to believe that any other form of mining could have attracted so little interest. This may be explained locally by the fact that there is no market for cinnabar ores as such, and that to convert even high-grade cinnabar ore into money, it is necessary to have access to a furnace. Few, if any, of the larger companies purchase outside ores. Another reason is that, as far as most of California is concerned, quicksilver ores are found only on agricultural patented land, so that the prospector, the forerunner of any new mining industry, is not permitted to search for mineral on such land, nor could he, should he find a valuable deposit, gain any of the advantages of which he continually dreams, and which are necessary to keep him on his quest. An advantage enjoyed by most of the Pacific Coast operators is that their mines are in localities where weather, labor, and supplies are satisfactory.

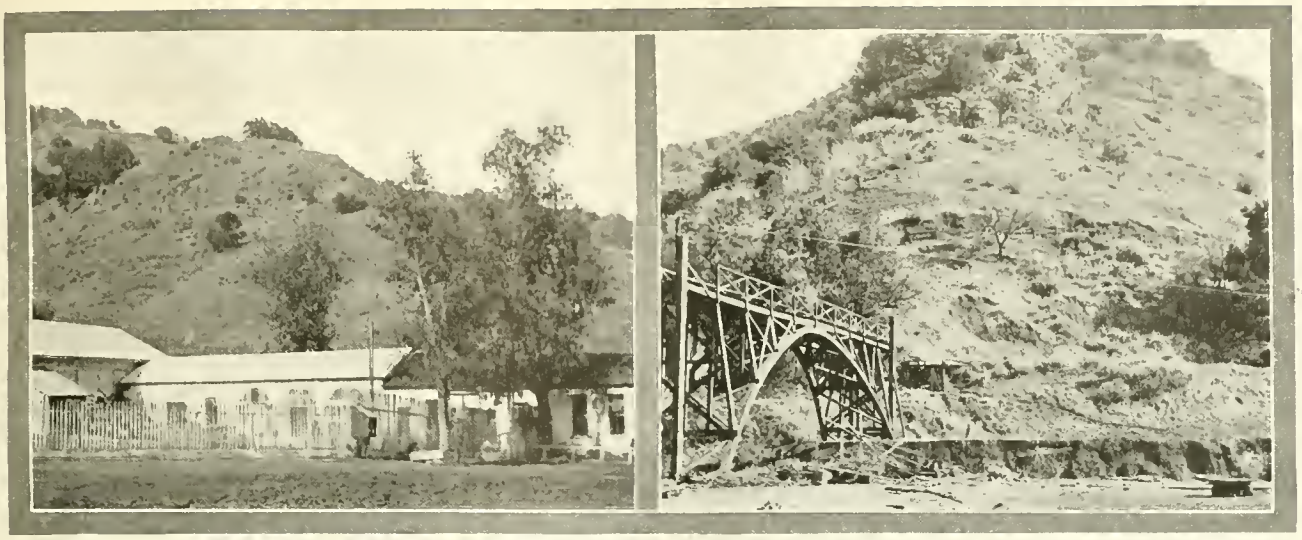


MAP SHOWING QUICKSILVER DEPOSITS OF CALIFORNIA, AND THE REASON WHY SAN FRANCISCO IS THE PRINCIPAL MARKET FOR THE METAL IN THE UNITED STATES.

Cinnabar ores are reduced by a process of distillation, that is, the ore is heated to such a temperature (about 625°F.) as is necessary for the oxidation of the sulphur

*Manager for the New Almaden Company.

†George F. Becker, U. S. G. S. Monograph, XIII, 1888. 'Quicksilver Resources of California,' by William Forstner, J. W. C. Maxwell, Charles G. Yale, and E. P. Preston, California State Mining Bureau Bulletin No. 27, 1908.



OUTCROPS OF QUICKSILVER LODE AT NEW ALMADEN.

and the vaporization of the remaining mercury. These vapors must then be cooled below the boiling point of mercury and condensed in an apparatus that is both costly and inefficient. The method of treating cinnabar ores as at present practised has undergone practically no change or improvement since 1871, when Robert Scott and his co-workers developed what is known as the tile furnace at New Almaden. Prior to that, only coarse ore, larger than a hen's egg, could be successfully reduced in the various types of furnace, it being necessary, in order to handle the fine, to press it into bricks and burn these in the coarse-ore furnace. The Scott furnace permitted the treatment of material the largest of which did not exceed two inches, and has made possible the persistence of the quicksilver industry. Modifications of the Scott furnace have been attempted, but no really new type of furnace has been developed beyond the experimental stage. The small operator has favored the retort-furnace, on account of its low first cost; but the small capacity, together with the high fuel consumption and the danger to the workmen has caused them to be abandoned by all of the larger operators, with the possible exception of those who still use some sort of retort for treating mercurial soot.

It would seem to be an easy matter to heat an ore to the proper temperature, reducing the sulphide and distilling the resulting metal, but a little investigation will indicate that while the theory is simple, the many mechanical difficulties tend to make the final result unsatisfactory. The bringing of the ore up to the proper temperature does not offer any particular difficulties, and, as it is not necessary to add any additional reducing agents or fluxes, the process is further simplified, but the resulting vapor gets into crevices in the brick-work about the furnace and condensers; in fact, it will escape through the pores of the apparatus. It is one of the most penetrating vapors known, and after being cooled below its condensing point, it exists as a fog, extremely heavy to move by ordinary draft. While hot, it will penetrate even concrete until it reaches so near the outside of the wall that it is sufficiently cooled to condense its mercury. I have even known it to penetrate to the centre of the walls of vitrified tile-pipe without apparently destroying the glazed surface. The mortar-joints in the brick-work become literally saturated, and it can be readily imagined the enormous value that is locked up in the modern furnace and condenser, where 400,000 to 500,000 bricks are used. Like all furnaces, it is necessary to have a dust-chamber either connected with the furnace or immediately adjacent; this chamber will confine a large amount of mercury vapor in the dust, which on being cooled is either lost in the atmosphere or condensed into microscopic globules of mercury difficult to separate from the dust.

As to the gases escaping from the furnace, they consist of products of combustion with the usual hydrocarbons derived from the burning of wood or oil, namely, N, NH_3, CO_2, SO_2, SO_3, H_2O, CO, and lastly the vapor of mercury. The sulphurous gases attack any material of which furnaces or condensers can be made, and the soot deposit from the burning of the fuel mechanically holds most of the condensed mercury. Crude oil, as burned in many of the large furnaces, makes a particularly greasy soot that prevents the small globules of mercury from coalescing and must be handled in a different way from the soot resulting from the burning of wood for fuel. As soon as the furnace-gases are cooled below the boiling point of water, the SO_3 becomes sulphuric acid and quickly eats out any of the metal-work with which it comes in contact. Such mercury as collects in the bottom of the condensers, on account of its extraordinarily high specific gravity, is forever seeking a crevice in which to hide, and it is not uncommon to find a condenser-bottom consisting of several feet of apparently solid masonry or concrete allowing the quicksilver to escape while retaining the water that is condensed with the quicksilver. Attempts have been made to prevent the ultimate loss of this mercury by putting iron plates across the entire top of the foundations on which the condensers and furnaces are built, and this method

is successful up to the time that the sheet iron is eaten away by the acid waters. Where ores containing a comparatively low percentage of sulphur are treated, cast-iron even in moderate thicknesses lasts very well and a good grade of redwood or pitch pine is apparently resistant to acid, but the difficulty of fastening such wood without the use of metal nails, bolts or screws is obvious. Most condensers have been built out of brick or masonry, and it will be immediately realized that the non-conductivity of such material tends to prevent the very object for which it is erected, that is, the carrying away of the heat from the enclosed vapors and their consequent condensation. Cast-iron condensers have been tried and in most cases are ideal when properly designed for this purpose. The high cost of cast-iron prevents its general use.

Condensers built of ordinary window-glass have been employed, and it is difficult to understand why the use of them was discontinued. Water-backs of iron have been tried, and while they assist in cooling the gases, this very fact results in their being rapidly corroded by acid waters. Vitrified tile-pipe makes a successful condenser, and should be more generally employed. The difficulty of cleaning many pipes of comparatively small diameter, no doubt, has prevented a more extensive use of such designs. Mercurial vapors will stick to the walls of a condenser to such an extent that it is necessary, in order to secure an adequate clean-up, to brush or wash these walls. This suggests immediately the difficulty of transporting the liquid mercury and condensed waters to the point where they are collected, and brings prominently to the front one of the sources of considerable loss, namely, the question of the finely divided mercury, which insists on floating on the water.

Even the largest companies seldom make any attempt to determine the efficiency of their operations. Assaying and sampling of ores, or of the cinder going over the dump, are seldom practised, it being usually deemed sufficient to estimate roughly the number of tons of ore 'burned,' and figure its value from the resulting number of flasks of quicksilver cleaned up at the end of a given period. The use of such metallurgical devices as pyrometers and gas analysis is practically unknown, and sampling of the material discarded from the furnace is usually done by means of an ordinary miner's pan. When panning the cinder or tailing, it is customary to take a random sample, discarding all of the coarser lumps after a casual inspection, and panning out the remaining fine to see if any cinnabar or metallic mercury is being lost. No doubt, there are many times when larger pieces are not thoroughly 'cooked' and the operator remains in ignorance of the fact that his furnace is not doing all that is required of it, simply because on panning the fine, little or no cinnabar or mercury is found. This haphazard method was all very well when quicksilver was worth 50 cents per pound, but when each pound is worth $4, the question of recovery becomes insistent. The New Almaden company is making a careful study of this problem. We have found it necessary to discard many existing methods and attack the proposition on an entirely different basis. When experiments now being tried are completed, a further contribution to the subject will be made.

Work of San Francisco Mint

The local Mint's business showed an increase of $72,000,000 in 1915 compared with that of the previous year, according to the superintendent, T. W. H. Shanahan. The source of the gold was as follows:

British Columbia	$18,689.24
Northwest territory	439.99
Mexico	488,975.95
Central America	218,121.22
South America, exclusive of Peru	12,293.35
China	9,573,342.04
Russia	1,921.59
New Zealand	3,378,614.70
Japan	19,408,110.75
Other countries	183,487.56
Australia	35,006,290.55
Peru	1,398.74
Total foreign coin and bullion	$68,291,685.68
United States, including Alaska and California	51,577,823.99
Total receipts	$119,869,509.67

The superintendent, T. W. H. Shanahan, reports that from its organization to December 31, 1915, there has been executed at the United States Mint at San Francisco, coinage amounting to $2,000,591,286.87, of the following denominations:

Gold	
Double eagles	$1,443,920,520.00
Eagles	141,974,060.00
Half eagles	138,940,040.00
Quarter eagles	1,861,255.00
Three dollars	186,300.00
One dollar	90,232.00
P. P. I. E. octagonal $50	75,450.00
P. P. I. E. round $50	75,500.00
P. P. I. E. quarter eagle	25,042.50
P. P. I. E. one dollar	25,034.00
Total gold coinage to end of 1915	$1,727,173,433.50
Silver	
Dollars	$109,523,073.00
Trade dollars	26,647,000.00
Half dollars	32,587,445.50
P. P. I. E. half dollars	30,000.00
Quarter dollars	11,465,534.25
Twenty cents	231,000.00
Dimes	8,637,218.90
Half dimes	119,100.00
Total silver coinage to end of 1915	$189,240,371.65
Minor	
Five cents	$426,350.00
One cent	333,060.00
Total minor coinage to end of 1915	$759,410.00
Total U. S. coinage to end of 1915	$1,917,173,215.15
Total foreign coinage to end of 1915	83,418,071.72
Grand total coinage to December 31, 1915	$2,000,591,286.87

REVIEW OF MINING

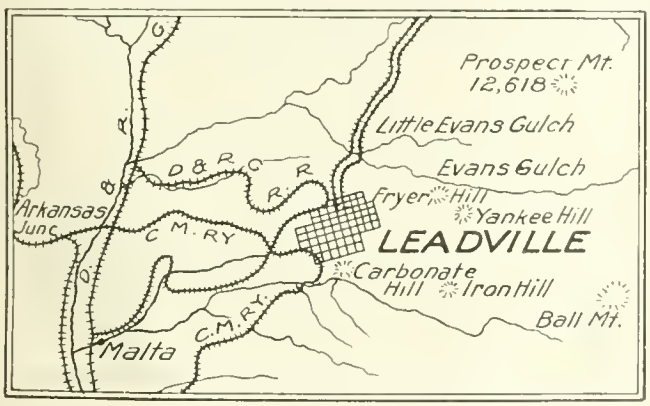
As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

DRAINAGE AND DEVELOPMENT OF ANOTHER IMPORTANT AREA, THAT OF FRYER HILL. THIS, WITH THE DOWN TOWN SCHEME, WILL MAKE AVAILABLE A LARGE AREA.

Fryer hill, the scene of the most famous ore-shoot of Leadville's early days, is again to be exploited on a large scale. The United States Smelting, Refining & Mining Co., well known in North America, is behind the enterprise. The entrance of this company into the Leadville district marks its first venture in Colorado, and the Fryer Hill undertaking, which will be in the direct control of the United States Smelting, Refining & Exploration Co., a subsidiary of the U. S. S. R. & M. Co., will be known as the Leadville Unit. This company has for its particular object the examination and purchase of metal mines, and the operation of properties which it controls under lease or by option.

Two of the company's engineers, Messrs. Funston and Enos, came to Leadville in December to investigate the Fryer Hill territory, and on receipt of their report C. W. Van Law, vice-president and general manager of the Exploration company, and A. P. Anderson, general manager of the Pacific Coast hold-



PART OF THE LEADVILLE DISTRICT.

ings of the company, visited Leadville for several days and decided to undertake the exploration of the property. Mr. Van Law spent several days studying the situation, and its exceptional possibilities appealed to him. The first work is the draining of the area included in the Fryer Hill basin. Machinery for unwatering the ground was ordered, preparations were made for the erection of new surface buildings, and repair of the old ones at the Harvard shaft, through which the water will be pumped. The company has opened offices at Leadville in the Vendome, in charge of H. S. Lee, resident manager of the Leadville Unit. Mr. Lee has been with the company for the past eight years and is a mining engineer of wide experience. So rapidly and well were the plans effected that a large electric hoist, one of several that will be used by the company, has already arrived here, awaiting removal to the Harvard shaft.

The mechanical and construction work is under the supervision of E. A. Hamilton, also of considerable experience, who has recently been associated with Mr. Lee in mining operations in Oregon.

The successful promotion of the Fryer Hill enterprise is the fruit of a long, concerted, and determined effort on the part of two Leadville mining and business men to bring the undertaking to a head. Several previous attempts to operate the territory failed, as the promoters were unable to secure all of the ground included in the Fryer Hill basin, without which the scheme could not succeed. These repeated failures served to impress mining men who were most familiar with the situation with the exceptional possibilities and the immediate resources of the area. Over a year ago, John Harvey and Norman H. Estey outlined a plan for obtaining leases on the desirable properties in the Fryer Hill basin. Mr. Harvey enjoyed a wide acquaintance in mining and business circles, and was able to make such rapid headway that by the end of the year he had most of the territory controlled; Mr. Estey had operated several large properties on Fryer hill, and with his father, the late Robert B. Estey, derived an intimate knowledge of the geology of the area. The data he was thus able to give enabled the partners in promoting the enterprise to present the facts with accuracy and completeness. The entire area comprising the Fryer Hill basin was secured under lease early in January. In the meantime the promoters were busy endeavoring to interest people in the scheme for the purpose of financing it. Not until six weeks ago was this question settled, when Mr. Harvey came in touch with some of the prominent mining men identified with the U. S. S. R. & M. Co. The result is as described above.

The Harvard shaft, on the north-west slope of Fryer hill, is the scene of the present operations of the company. This is a 4½ by 14-ft. three-compartment shaft 407 ft. deep. It is flooded from the 250-ft. level, and the work now underway is preliminary to the unwatering of the property and surrounding territory.

Pumping equipment will consist of one seven-stage, deep-well, electrically-driven centrifugal pump by a 75-hp. motor. The deep-well or 'shoe-string' pump discharges directly into the suctions of two five-stage Krogh centrifugal station-pumps, which will lift the water to the surface. The pumps are manufactured in California, and have been used with great success by the company in its operations at Pachuca, Mexico. They are expected to lift from 1200 to 1300 gal. per minute. In order to expedite drainage, bailers will be used, working in counterbalance, in two compartments of the shaft. These will haul an additional 500 gallons.

It is estimated that the installation of machinery and the complete equipping of the surface-plant will require a month. Three months is the time that has been set for the drainage of the ground, so that by the first of July active mining should be underway. This will consist largely of exploration work at the 400-ft. level, which is in the upper or blue limestone contact. The first step will be the sinking of the shaft a distance of 300 ft. through the parting quartzite into the white lime, a zone that has proved remarkably productive on Carbonate hill, but which has never been explored on Fryer hill. Other shafts controlled by the company will be put into operation as they are needed. Drill-holes will be put down at certain points and a thorough campaign of prospecting will be carried out during the rest of the year.

The territory controlled by the company comprises 200 acres of the choicest mineral ground in the Leadville district. In the past it has produced millions of dollars by development that went no deeper than the parting quartzite. The possi-

bilities of the zone under this division will cannot be estimated.

However, the development of Fryer hill is not the greatest factor or the most important feature in the entrance of the U. S. S. R & M. Co into the Leadville district; the policy of the company is one of expansion. It plans an exhaustive inspection of mining territory not only in the Leadville district, but also in the other large mining centres of the State. It contemplates the development of large enterprises like the one now underway throughout Colorado. Following the campaign of exploration, the company has outlined plans for the erection and operation of large mills and smelters for the treatment of all ores taken from its holdings. Leadville is looked on as the site for the first of the smelters to be built in Colorado, and it will come as a part of the work now in progress. Should the orebodies that are to be uncovered in Fryer hill prove as extensive as is anticipated, the smelter will be erected as soon as the company finishes the work of prospecting the territory.

Mining men look for big things in the Leadville district during the coming summer. The Down Town basin is being drained through the Penrose shaft, where very satisfactory progress is being made. Fryer hill, considered by experienced miners the richest piece of territory here, is assured of draining and extensive development. There are bright prospects for the unwatering of East Carbonate hill, the only large area yet to be drained. Following the pumping of water from these areas there will be an extensive campaign for deep mining throughout the district. All of this gives an optimistic feeling at Leadville.

WASHINGTON, D. C.

Mining Law Revision.—New Safety Bureau Proposed.

Legislation in Congress over the proposed revision and codification of the mining laws proceeds slowly. The latest information is that Representative Foster, chairman of the committee on mines and mining of the House, is preparing a bill revising and codifying the mining laws, which he will complete with all speed and introduce into Congress, probably before March 1. The bill is to be wholly tentative, and it is intended to be the nucleus out of which shall grow the true bill the House committee will recommend for passage to the House of Representatives, and which shall comprise the codification Congress will enact, subject to such changes as the Senate may decide to make, if any.

A piece of legislation that has passed the House and is now before the Senate, creates a Bureau of Labor Safety. It is of importance to mining men. It was introduced by Representative Mann, the Republican floor leader of the House. Mining men have fought it on the ground that, written as it is, it would supplant the department of safety now in the Bureau of Mines, or at least establish a superior direction of that Bureau, thus robbing it of its present independence. It is declared that, while it is true that the bill carries wording that its contents shall not be held to repeal any previous legislation appertaining to labor safety, the safety provision in the Bureau of Mines being thus seemingly attended to, the provision does not cover the situation, and that left as it is it means trouble for the Bureau in its enforcement of its own will regarding the safety of labor in mines. It looks as if a dual field was being created with all its attendant rivalry, to say nothing of expense. Mining men want explicit declaration in the bill that the existing safety of labor laws appertaining to the Bureau of Mines shall be excepted from the purview of the Bureau of Labor Safety bill. Mining men are for co-operation with that Bureau, but want the present establishment in the Bureau of Mines to be absolutely independent. In the Senate the Mann bill is known as the Kern bill, and it is thought that it will be passed there; but mining men still hope to have it amended in accordance with their desires.

BUTTE, MONTANA

Frozen-Ore Troubles.—Zinc.—Anaconda in South America.—Elm Orlu Electric Hoist.—Sinking the Colorado Mine.—Pilot-Butte.—Alex Scott Sale.

The Anaconda company's copper production decreased 20% during January on account of the excessive cold weather at Butte. The ore froze in the bins and railroad-cars, and the thawing facilities at the smelter proved to be inadequate. These have been improved, and 100 additional steel-hopper cars have been ordered, so the company is better prepared to operate through a long cold season if the necessity again arises.

The old Lexington shaft at Walkerville has been pumped out to a depth of 1000 ft. The upper levels are being prepared and 100 tons per day of zinc ore is being hoisted.——At the Alice, which is near the Lexington, a large number of men are at work in spite of the appeal of the minority stockholders who attempted to have the sale to the Anaconda company set aside. The water is down to 800 ft., and the shaft is being re-timbered.

The East Colusa, at Meaderville, will soon begin operations as a zinc mine. It is an old copper producer, and has been shut-down while the shaft was being re-timbered. Its output will be shipped to the leaching plant at Anaconda.

It is planned to have the new zinc concentrator at the Washoe plant completed by July 1. It will have an initial capacity of 2000 tons per day, and will treat ore from the Lexington, Alice, East Colusa, Nettie, Emma, East Gray Rock, and Poulin mines. An oil-flotation process will be used on the slime, and the concentrate will be shipped to the leaching plant that is now under construction at Great Falls.

The Anaconda company's new operations in South America have attracted considerable attention. Through subsidiaries it has undertaken the development of the Potrerillos copper property in Chile. Three companies have been organized to continue the work, namely, the Andes Copper Co., with a capital of $50,000,000; the Andes Copper Mining Co., with a capital of $50,000,000; and the Potrerillos Railway Co., with a capital of $5,000,000. The preliminary work has been done through the medium of the Andes Exploration Co., which has a nominal capital controlled by Anaconda. An 80-mile railway will be constructed by the Potrerillos company from Pueblo, Hundida, on the Government railway in Chile, to the side of the proposed reduction-works and mines. Actual ownership and operations of the mining properties will be vested in the Andes Copper Mining Co., while the Andes Copper Co. will hold stock of both the railway and mining companies. The Anaconda Copper Mining Co. will hold the majority stock of the Andes Copper Co., while the minority interests is held by William Braden and associates, who brought the property to Anaconda's attention. It is understood that 75,000,000 tons of ore averaging 1.8% copper has been developed so far, with indications of far greater quantities. Mill tests have been made to demonstrate the best methods of treatment, and it is probable that flotation will be employed. Surveys for the railroad and reduction plant have been made, but it will be several years before Potrerillos enters the producing ranks.

The new hoist ordered for the Elm Orlu will have an 1800-hp. direct-current motor driven from a fly-wheel motor-generator set. It will hoist five tons of ore in counter-balance from an ultimate depth of 3500 ft. at the rate of 2500 ft. per minute. The hoist can haul the same load out of balance at about half this speed. In case the main line switch opens from an ultimate depth of 3500 ft. at the rate of 2500 ft. per hoisting by using the energy stored in the fly-wheel.

The Butte & London shaft is down below the 1300-ft. level; it will be sunk 200 ft. more, and the cross-cuts will be driven on the 1500-ft. level.

The Colorado mine of the Davis-Daly now has a three-com-

partment shaft from the surface to the 2500-ft. level. While it was being sunk, a sinking engine was used at 1500 ft., and a solid rock bulkhead was left in two compartments between 1700 and 1900 ft. to protect the miners working in the bottom. From 1900 ft. the shaft was carried down full size to 2500 ft. The removal of the rock bulkhead interfered with hoisting operations, and the production had to be curtailed until the work in the shaft is completed. Full shifts have been resumed and production is again normal. A recent rumor to the effect that another assessment would be called caused shares to drop from $2 to $1.25; the rumor is officially denied and sufficient working capital is on hand for all needs. A new hoist will be installed, as the old one is not large enough to hoist from a depth of 2500 ft. The company's Hibernia claim is one of the most promising of the old silver mines that are being prospected for zinc. It adjoins the Nettie of the Anaconda company, which has been unwatered to a depth of 500 ft., and it is probable that arrangements will be made to explore the Hibernia from the Nettie shaft.

At the Pilot Butte about 60 tons of ore per day is being mined that will average about 5% copper. From this the company is receiving sufficient to pay for not only mining expenses, but also the cost of the development now being carried on in the lower levels. Driving at 2500 ft. has opened an orebody that will materially add to the ore reserves. The property is on a paying basis, in spite of the fact that no ore is being taken from any of the disputed orebodies that were tied up by litigation with the Anaconda company.

The sale of the Butte-Alex Scott mine to the Anaconda company has been ratified by the stockholders of the smaller company. The purchase includes the little Annie claim, and the east 500 ft. of the Alex Scott claim. The Alex Scott adjoins the West Colusa, which is owned by the Anaconda company. The consideration was $750,000 cash. This sum, together with the money in the treasury, will make each of the 79,311 issued worth about $10.

PLATTEVILLE, WISCONSIN

Conditions in the Zinc Region During January.

Severe winter weather made milling operations extremely difficult, and free delivery of ore to rail sometimes impossible during January, resulting in a considerable tonnage of zinc concentrate piling-up at some points, and a curtailed output at others. Recent work in refining crude concentrate is resulting in high efficiency at times, 62% zinc concentrate now being regular at three of the new plants started within the last 90 days.

Blende of all grades continued in excellent demand during the month, except in the closing week. The base then had receded to a point under $100 per ton, the highest going at $110; $55%, $80 to $90; 50%, $70 to $80; 45%, $50 to $55; 40%, $45 to $50; and 35%, $35 to $40. Less than two years ago zinc producers said that fair profits were realized with 'jack' on a basis of $40 per ton for 60% metal content. This price was easily obtained for the lowest grade now recognized in the current quotations on graded stuff.

Regarding the future status of zinc ore the Press correspondent secured interviews with leading officials, east and west. One prominent man of the New Jersey Zinc Co. confidently expressed the opinion that zinc-ore prices will be maintained for the next two years. Another smelter of national reputation observed that prices would be well maintained until well along into the autumn of 1916, when they would weaken; but he did not think the low standards prior to August 1914 would come for several years. A third, representing a large eastern mining syndicate, largely engaged in the production of zinc ore in both the Wisconsin and Missouri fields, and an ore-buyer of no small pretense, pointed with satisfaction to the situation in the galvanizing trades, declaring that about 60% of capacity was idle, and that a forward buying movement must soon take place in volume, since much dissatisfaction exists in sheets and painted materials offered as substitutes for galvanized material. This last mentioned source of information conveyed encouragement to all producers predicting higher prices for blende. The end of the month saw the range widened, running from $85 to $105 per ton, and giving buyers wider latitude in submitting bids. The reserve in the field at the close of the month exceeded 3000 tons, but this newly-accumulated output was not due to prices so much as to bad roads, which at times entirely isolated outlying producers.

The lead-ore demand was good, opening at $72 to $78, and receding, only to gain the ground lost quickly and coming back stronger than before when the high price of $82.50 was reached. This is near the high mark of 1906, when the price reached $90 per ton.

Producers of pyrite experienced slight advances in the price of fines, recovered at separating plants. Deliveries were made under contract, but statements from buyers showed that sales were made uniformly on a basis of $4 per ton, 30% basis.

Miners in the northern section of the field suffered more on account of weather and roads than did those in the south half of the field; the former are farther removed from rail. Producers of carbonate zinc ore are at a greater disadvantage than jack miners, since milling is confined more to open-air washplaces. Prices for zinc carbonate ore ruled high, rising steadily at $70 to $80 per ton, 40% base. Several hundred tons of ore was carried over. Shipments were light, on the whole, and prices sadly out of tune with the ruling quotations.

Building operations at all points in the field suffered no setbacks during January. Several new producers with entire modern equipment were ushered into active existence. Drilling operations were given impetus at several points in the field by the introduction of new drilling outfits brought-in from other parts of the country. Road building in the southern districts made substantial gains. New capital came into the field, several cash transactions being responsible for the transfers of newly-developed properties. The gross turn-in of crude concentrates for the month was 27,012,000 lb., and net deliveries to smelters 15,310,000 pounds.

For the first time in the history of this mining region, strikes of a rather serious nature developed. Shovelers receiving 8c. per can per shift record of 50 cans or more, walked out in three districts, demanding a uniform rate of 8c. per can. Operators not only refused to meet the demand, but promptly shut-down their mines and plants. New gangs of men were hastily recruited, and operations resumed under police surveillance. Trouble was brewing, but no disturbances were manifest aside from individual encounters, two resulting in stabbing affrays. The foreign element of miner is principally involved.

TORONTO, ONTARIO

Silver and Mining Supplies.—Quebec Mining Law.

Notwithstanding the recent increase in the price of silver, profits of the Cobalt companies have been lessened owing to the considerable increase in the cost of mining supplies. Since the beginning of the War, blasting-powder has about doubled in price and all steel products have advanced considerably. In fact, prices all round have risen so that the question of keeping down operating costs has become a serious problem. At some of the mines drastic measures of economy are being enforced.

The Quebec mining law is being amended to facilitate operations by small prospectors. The minimum size of a mining concession will be reduced from 100 to 40 acres. The price of lots on the north shore of the Gulf of St. Lawrence, where blacksand deposits hold out good prospects for iron mining, will be reduced.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

In January the Alaska Gastineau mill treated 119,914 tons of ore averaging $1.37 per ton, against 111,183 of $1.36 in December.

ARKANSAS

Bad weather reduced zinc production in north Arkansas in January, the roads between Rush and Yellville being considerably cut up. The output from 12 mines was 40 carloads.

ARIZONA

COCHISE COUNTY

Tombstone is considerably busier than for a long time. At its Bunker Hill property Phelps, Dodge & Co. are employing 400 men. The old mill is working at part capacity. A good deal of manganese ores is being shipped. Wages were increased 10% on February 16. Emil Grebe is superintendent.

After over a two years' lease, the property worked by the Higgins Leasing Co. in the Warren district, has reverted to the owner, Thomas Higgins of Los Angeles. During the lease a considerable quantity of copper ore was extracted, and good dividends were paid.

GILA COUNTY

At the Inspiration mill 17 units are in operation. Additional men have been taken on underground. On account of trouble with the railway, shipments of silicious ore from the Live

PROPERTY MAP OF MIAMI, ARIZONA.

Oak mine to the International smelter have been interrupted lately.

At the Old Dominion the flow of water has increased to 11,000,000 gal. per day. No. 12, 14, and 16 levels are producing 1000 tons of ore daily through the A shaft. The Kingdon shaft will be down to No. 16 within a month. At the smelter three furnaces are in blast, and two converters. Over 100 tons of fine concentrate is briquetted per day for the furnaces. Some concentrate goes to the International smelter. The mill treats 700 tons daily.

GREENLEE COUNTY

The Shannon mine is reported to be operating at nearly full capacity again, and the February output will be 750,000 lb. copper. The effects of the strike were soon smoothed over.

Trouble between unionists and non-unionists at the Detroit mine on February 11 resulted in 900 men going out on strike again. Similar trouble at the Shannon also led to 100 men walking out. It is alleged that the union men threatened the others, and the superintendent discharged the unionists.

The strike was settled on the following day by re-instating the discharged men. The union officials considered the walkout premature. Non-union men are to be kept on; 20% of employees do not belong to the union.

MOHAVE COUNTY

According to the Chloride Mining Bureau the Chloride district produced gold, silver, lead, zinc, and copper worth over $3,000,000 in 1915. The Bureau has been organized for reliable publicity purposes, with L. V. Carothers as secretary. The new mill at the Golconda zinc mine has electric power service now. The 200-ton flotation plant will treat tailing as well as current mine ore.

At 665 ft. in the United Eastern at Oatman the cross-cut shows 37 ft. of ore assaying from $15 per ton up.

YAVAPAI COUNTY

From the 1400-ft. level of the United Verde Extension 15% copper ore is reported to have been opened; while another cross-cut at that depth has passed through 30% ore, the downward extension of the 1200-ft. shoot. The new hoist of 1000 tons' daily capacity is working well, also the new 5000-ft. tramway from the mine to the Clarkdale railway.

Encouraging developments are reported from a score of mines in the Zonia district.

A flotation plant is to be installed at the old Tiger mine to treat 10,000 tons of $8 tailing. The Flotation Recovery Co. is in charge.

CALIFORNIA

CALAVERAS COUNTY

(Special Correspondence.)—The manager of the Calaveras Copper Co., S. M. Levy, reports that during the past year the principal work in the mine has been done in extending levels along the lode, mostly on the fourth. Marketable ore has been opened for 1500 ft. along this level. The sixth level has also been opened, but not so extensively as the fourth. Considerable work has also been done on No. 10, the lowest, a vertical depth of 800 ft. The character of the ore to this level is unchanged from that near the surface, being principally chalcopyrite. During the year a rock-breaking and sorting-plant was erected at the Union mine, one of the company's properties, the plant having a capacity of from 200 to 250 tons per day. The ore is broken here and passed over a belt from which some of the ore of shipping grade is hand-sorted, the remainder going to the mill by an electric tramway, a half-mile long. The mill has a small flotation plant installed for experimental work. This mill is now being replaced by one of larger capacity. The first unit of 250 tons daily is nearing completion, and it is anticipated that this mill will be equipped with ball-mills, Dorr classifiers and thickeners, and Oliver filters, all driven by motors. It is expected that if this initial unit operates satisfactorily another of 250 tons capacity will be installed during the late spring or summer.

Copperopolis, February 1.

INYO COUNTY

High prices of zinc and lead, substitution of an aerial tram in place of haulage by teams, electric-power service, and encouraging development, have combined to make prospects at the Cerro Gordo mines, near Keeler, very satisfactory. Seventy

men are employed. The output in 1915 was 4,440,666 lb. zinc, 121,510 lb. copper, 748,952 lb. lead, 126 oz. gold, and 112,541 oz. silver. Old workings and dumps contain a large quantity of material for treatment.

Lake County

Efforts are being made to finance the Abbott quicksilver mine in the Sulphur Creek district. The mine has been extensively opened, and has produced a good deal of mercury. A Scott furnace forms part of the equipment. Dumps contain a good quantity of ore.

Santa Clara County

The old Guadalupe quicksilver mine, 10 miles south of San Jose, has been purchased by H. C. Davey and others for a high price. They were lessees from the Coleman estate, and bought the property when the lease expired. A complete reduction plant is in full working condition.

At New Almaden a considerable amount of new work is under way, especially metallurgically.

Shasta County

As long as copper is 20c. or over, the Mammoth, Mountain Copper, and Balaklala companies will pay their men 25c. per shift extra. A total of 1830 men are affected.

It is proposed to enlarge the Uncle Sam mill and try flotation. The ore is mostly gold-bearing.

The U. S. S. R. & M. Co. has acquired 2000 acres on Big Backbone creek, adjoining the Mammoth holdings, from Charles Butters and others for $75,000.

Yolo County

The old Reed quicksilver mine, in the western part of this county, has been sold to Breed and Bancroft of Oakland for $5000. The adits and plant are in bad order, and must be renewed at considerable cost. The mine has produced several thousand flasks of mercury.

COLORADO

Conejos County

(Special Correspondence.)—The old Summitville-Platoro mining district in southern Colorado is on the eve of a great revival. The large orebodies opened years ago, too low grade to ship from this isolated district, and too refractory for treatment by cyanidation, are now being tested by flotation processes from several of the old properties. Preliminary tests show a far better recovery of metals by flotation than by any other method. It is reasonably certain that flotation is especially adapted to these ores, and that mills employing this process will be installed on some of the most developed properties this year. There are a number of undeveloped claims in the district showing good bodies of low-grade milling ore on the surface, that only need development to open a large tonnage of good-grade ore. The greatest need of this district at the present time, is the erection of a custom-mill to treat the ores from these smaller properties at reasonable charge.

Platoro, February 5.

IDAHO

Shoshone County (Coeur d'Alene)

Following the increase of wages announced by the Bunker Hill & Sullivan and other companies at Kellogg and Wardner last week, all of the other companies in the Coeur d'Alene have adopted the sliding-scale. About 5000 men will benefit, while metals are high, making a total increased pay-roll of over $1,000,000.

High-grade tungsten ore (scheelite) continues to be shipped from the Golden Chest mine near Murray.

MICHIGAN

The Copper Country

(Special Correspondence.)—Owing to the blizzards during January, the worst for 30 years, the copper output of the region was 7,000,000 lb. below the yield of December, and 9,000,000 lb. under what was anticipated, the total being 20,000,000 lb. February also started badly.

The White Pine mill is working two shifts daily, yielding equal to 6,000,000 lb. of copper per year. The ore contains 30 lb. per ton.——At the White Pine Extension 75 men are employed. Recent diamond-drilling shows rich ore, the best being in shale.——Other companies are busy in the area adjacent to White Pine.

Houghton, February 12.

Owing to the water of Lake Linden freezing around the suction-pipe of the Calumet & Hecla dredge, there has been considerable trouble in lifting sand for the re-grinding plant. A 1250-hp. pump has replaced that of 750 hp. The sand nearest the shore is of better grade than that farther out.

By the increased bonus of 5 to 10% monthly, 1500 men at the Wolverine and Mohawk mines will benefit.

MONTANA

Silverbow County

(Telegraphic Correspondence.)—Fire broke out near air-shaft of 1200-ft. level of the Anaconda company's Pennsylvania mine on February 14, where 220 men were working. Gas and smoke quickly filled the upper levels. Fourteen men were asphyxiated; seven are missing. Station-men and foremen quickly hoisted the shift, saving 200 lives. Mine rescuers with helmets did good work; pulmotors revived many. Water was poured down air-shaft. The big exhaust-fan installed makes the air-shaft upcast, hoisting shaft is downcast. It is expected to clear the mine of smoke and gas to permit of an examination. The fire is burning fiercely. Openings to adjoining properties are bulkheaded. Many deeds of heroism are recorded. Assistant-foreman wearing helmet and one member of helmet squad are dead. Helmet-men are working 10-minute shifts.

Butte, February 16.

A cross-cut at 2600 ft. in the Anaconda company's High Ore mine has reached the boundary of the Butte-Ballaklava, equal to the latter's 2200 ft. level, showing 4 ft. of 4% copper ore. A cross-cut from the Ballaklava winze below 1600 ft. has opened 24 ft. of 2% ore.

NEVADA

Clark County

According to the U. S. Geological Survey a massive deposit of magnesite of unusual character has been identified in the valley of the Muddy river, a few miles above the town of St. Thomas. Railroad service is available three miles away at Kaolin. The mineral has been known as kaolin for sometime. The deposit is included between tilted beds of conglomerate and sandstone below and shale above. It is not a vein. Analysis show 36.72% magnesium oxide, 5.36% lime, 11.12% silica, 44.15% carbonic acid gas, and 0.98% alumina and iron oxide.

Esmeralda County

On March 6 the Reorganized Booth Mining Co. will pay 5c. a share, equal to $50,000.

The Pittsburg Silver Peak Gold Mining Co. has dismantled its mill near Blair. The company is examining the Rawhide mine at Sonora, California.

The Jumbo Extension company reports as follows for January: Ore shipped was 3123 dry tons, with a gross value of $81,500; freight, treatment, and sampling cost $28,250; smelting losses were $12,500; and operating costs $17,500, leaving a net realization of $23,250.

Elko County

Since January 1 the Clover Mining Co., near Wells, has shipped 24 cars of zinc carbonate assaying from 28 to 36% metal.

Humboldt County

At a depth of 1500 ft. in the Seven Troughs Coalition mine the shoot has widened to 16 and 20 in. of $500 ore.

Nye County

Tonopah mines last week produced 8454 tons of ore worth $177,432. Silver and concentrate shipments amounted to $215,867.

OREGON

'Minerals of Oregon' is the title of a University of Oregon bulletin by Graham John Mitchell. The publication consists of 60 pages, and was prepared to give students in economic geology as complete a list as possible of the minerals found in the State, together with their situation; and to give the people generally some idea of the minerals found in Oregon. The minerals are arranged alphabetically. Prospectors and others should secure a copy of this bulletin.

UTAH

Juab County

Better weather allowed increased shipments from Tintic last week, the total being 123 carloads.

Summit County

Park City shipments last week amounted to 1075 tons.

During January the Snake Creek tunnel at Park City was extended 410 ft., 90 ft. of which was bad ground. The total length is 14,122 ft., a depth of 3730 ft. from the surface. The Daly-Judge property will be entered in a few weeks. The flow of water is 9000 gal. per minute.

MEXICO

The Department of State at Washington, D. C., has issued under date of February 7, 1916, the following notice relative to the shipment of munitions of war into Mexico:

"In order to avoid confusion and delay in submitting to the Department of State applications for permission to ship munitions of war into Sonora, Chihuahua, and Lower California, the following mode of procedure is stated for the benefit of those who contemplate making such shipments: No munitions of war, such as powder, dynamite, blasting caps, mining fuse, guns, and ammunitions, etc., will be permitted to enter any of the sections mentioned without specific authorization of the President. Those desiring to take or ship munitions into any of the territory specified must make application directly to the Department of State, except that persons making shipments of munitions for the *de facto* Government of Mexico should submit their applications to the Washington representative of General Carranza. Full details as to amount, destination, American border port through which the shipment is to be sent, purpose for which intended, and names of shipper and consignee should be given with all applications." Mining companies should make note of this regulation.

El Oro

Fergus Allan and Alfred F. Main of the El Oro Mining & Railway Co. recently had an interview with Pablo Gonzalez in Mexico City, the result of which was a decree from General Obregon repudiating overt acts of El Oro strikers, which will probably put an end to strikes there. The Esperanza company has received enough cyanide and other supplies to last a year, and it is rumored it will resume on February 15. The other companies will probably soon follow. Dos Estrellas is also receiving some supplies.

Hidalgo

During December the Santa Gertrudis mine produced 19,841 tons of ore with a profit of $67,000.

Sonora

In order to prevent poor people entering this State without means, the Carranza government states that with the passports issued, everybody must have $50 in cash.

PERSONAL

H. C. Bosworth has returned to Mexico City.

Mark L. Requa has returned from New York.

A. E. Drucker is still at La Salada, Colombia.

H. Vincent Wallace is now living in New York.

Howard D. Smith has returned from New York.

H. W. Edmondson is in Madison county, Missouri.

W. J. Loring has returned to town from Tuolumne.

Scott Turner has returned from London to Lansing.

R. M. Geppert is at the Esperanza mine, El Oro, Mexico.

J. H. Farrell, of Los Angeles, is at Marquette, Michigan.

A. J. Eveland, recently at Pachuca, has gone to South America.

S. S. Rodgers is superintendent of the Anaconda company's zinc concentrator.

D'Arcy Weatherbe crossed in the *Adriatic* to New York on his way to Cobalt.

Fred Hellmann, manager of the Chuquicamata, has arrived in New York from Chile.

William Forstner is investigating quicksilver deposits in Siskiyou county, California.

Edgar Rickard spent the week in San Francisco, and is now returning to London, by way of New York.

Burr J. French is engineer for the Cinco Minas, Magdalena, Jalisco. These mines have operated steadily during the past year.

Thomas N. Miller has resigned from the staff of the Oriental Consolidated Mining Co., Unsan, Korea, to go to the Philippine Islands.

Reginald E. Callow is at El Tigre, Sonora. He reports that all the mines and mills in that part of Mexico are resuming operations.

George A. Camphuis, of the firm of Camphuis & Rives of El Paso, is operating copper properties for Eastern interests in Pima county, Arizona.

L. D. Gordon, well known at Cerro Gordo, California, has been elected president and general manager of the Round Mountain Mining Co., Nevada.

Wallace E. Pratt, chief, Division of Mines, Bureau of Science, Manila, P. I., has resigned and has been engaged in private work in Mexico since February 15.

Arthur B. Foote read a paper on 'Engineering Features of the North Star Mines' before the local section of the American Society of Civil Engineers at the Palace Hotel on February 18.

Frank M. Estes, manager of the Creston-Colorada mines, Minas Prietas, Sonora, has re-opened that property for the Mines Company of America. A full staff accompanied him to the mines.

Frank H. Probert is to lecture to mining students at the University of California on February 21, 23, 24, and 25, at 4 p.m. each day. The subject will be 'Outcrops and the Zone of Oxidation.' Lecture 1 will discuss the Anatomy of the Earth's Crust. Physical Forces at Work. No. 2. Life History of the Outcrop. Contributory Causes to the Constant Change. No. 3. Chemical Forces at Work. Migration of the Metals. No. 4. Significance of Surface Signs. Types. These lectures are open to the public.

The Colorado School of Mines announces that the U. S. Bureau of Mines will move its laboratory from Denver to Golden early in June. The two institutions will co-operate in investigation work. R. B. Moore and 10 assistants comprise the Bureau staff.

THE METAL MARKET

METAL PRICES

San Francisco, February 16.

Antimony, cents per pound	44
Electrolytic copper, cents per pound	27.75
Molybdenum: dull, 90% MoS_2, per pound	$1.40
Pig lead, cents per pound	6.55—7.50
Platinum: soft metal, per ounce	$85
Platinum: hard metal, 10% iridium, per ounce	$89
Quicksilver: per flask	$300
Spelter, cents per pound	21
Tin, cents per pound	43
Zinc-dust, 100-kg. zinc-lined cases, cents per pound	30

ORE PRICES

San Francisco, February 16

Antimony: 50% product, per unit	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	11
Magnesite: crude, per ton, f.o.b.	8
Magnesite: plastic, no iron and lime, calcined, per ton	30
Magnesite: refractory, 11% iron, dead-burned, per ton	35
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit of 20 lb. for spot	45

Tungsten ore has advanced $12 per unit in Colorado, $57 per unit being paid.

So many of those mining chrome, tungsten, molybdenum, and other ores write to us asking where they may dispose of their products that we call attention to the 'Buyers' Guide' on the last page of each issue. Under 'Metal Buyers and Dealers' are listed the firms with which we recommend that mine operators open negotiations. These dealers buy, or will refer you to buyers, of practically all ores at present in increasing demand.

EASTERN METAL MARKET
(By wire from New York.)

February 16.—Copper has a runaway tendency; lead is firm owing to foreign buying; zinc is active, there being a great scarcity of spot metal.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

A good undertone characterizes the silver market. London sees a healthy future for the metal, judging by the statistical position, as there have been large reductions in metal held at the chief silver using centres of the world since a year ago, especially in India, Shanghai, and London. In India the gold holdings are increasing, and silver decreasing, therefore purchases for Indian coinage are likely.

Zinc concentrate, 60% metal, sold as high as $125 per ton at Joplin, Missouri, last week, the market being strong. The Missouri-Kansas-Oklahoma region produced 7457 tons blende, 583 tons calamine, and 1147 tons lead, averaging $105, $83, and $85 per ton, respectively. The total value was $933,191.

The new electrolytic plant of the Anaconda company is expected to make a net profit of $4,000,000 per annum, provided the price of spelter does not decline.

Butte & Superior is producing 140,000,000 lb. of spelter per year, yielding a profit of $14,000,000, equal to $50 per share, that is, if prices are maintained.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.	1916.		1914.	1915.	1916.

June	30.72	40.26	....	Dec.	33.60	38.71	....

Tin is steady at 41.75 to 42.25 cents.

Eastern Metal Market

New York, February 11.

Spot copper has sold at 28c., June shipments are quoted at 27c. and July, August, and September at 26.50c. The market to-day deals principally with forward deliveries. London shows feverish strength, and has advanced to £134 for electrolytic. The situation is due to the enormous demand for copper to be worked into munitions of war, the manufacture of which is now at its height. The trade is simply bewildered by the extent to which the metal is being consumed, and at the indifference to high prices. No other period in the history of trade offers comparisions. Zinc has been in good demand in the past few days, and its quotations are steadily rising. Lead has gone up $3 per ton, following good export and domestic buying, in which premiums were paid. The tin market has been uneventful, despite perilous shipping conditions. The metal is arriving in generous quantities. Antimony is scarce and higher, and small consumers are in a quandary because of the guarantees exacted by the British government. Aluminum quotations are on the upward trend. Exports of the metals appear to be somewhat smaller than they have been, but this is because they are now going abroad in manufactured form more than in the raw state.

The steel situation may be summed up with the statement that many mills, both in the East and West are sold up for the year, with consumers looking into 1917. Ship-yards especially have sought to cover their needs for 1917, as well they might, with two and three years' work in their yards. The French government has purchased steel-rounds in the past few days, amounting to over 250,000 tons. Some mills have gone in so heavily for the War business that they cannot properly take care of their domestic customers; others have kept the interests of their regular trade in mind. The quotations of finished products vary so with deliveries that it is difficult to keep track of them.

COPPER

Both in the United States and abroad a most extraordinary situation exists in copper. In both New York and London prompt and nearby deliveries are difficult to obtain, and prices are soaring. Their level is entirely determined by the delivery specified. The real market is almost entirely in future positions. June shipments of electrolytic are quoted at 27c., while for a few carloads of spot metal 28c. has been paid. For July, August, and September 26.50c., 30 days, delivered, or 26.37c., cash, New York, is asked. Lake prices range about the same. Day after day the London market for electrolytic has advanced, demonstrating the futility of the effort of the Government to control prices there. By February 10 the London quotation had mounted to £134. The explanation of the whole situation is the tremendous consumption of copper in the manufacture of munitions of war. Millions of pounds are being worked into one form or another by consumers, new and old. Perhaps the two heaviest uses are in the production of cartridge brass, and in the extrusion of large rods from which the nose pieces and timing devices of shells are made. With practically all of the war contractors, price seems no object, and for the following reason: when they figure on a war inquiry involving copper, their first move is to ascertain what the copper will cost. They then base their estimate on the cost of material and manufacture, adding, of course, a generous profit. A producer of copper recently said in a quiet way, which carried conviction: "We can get almost any price for copper." However that may be, the 30c. level is near. France has been an especially heavy buyer. Canada is using great quantities as might be expected. Sheet-copper is quoted at 33c. base, and high sheet-brass 36 to 38c., and brass rods and wire at the same prices. In the week ended January 29, manufactured brass was the largest item of export, amounting to $1,597,029, according to figures compiled by the export department of the National City Bank of New York. Exports, up to and including February 10, totaled 6331 tons.

ZINC

All this week there has been a steady and strong demand for zinc, and quotations have advanced from day to day. The quotation on February 10 was about 19.50c. St. Louis, and 19.75c., New York. The scarcity of prompt metal lends strength to the market, and it is made stronger by reports of serious floods in the Joplin district, Missouri, which threaten to reduce the production of ore. The London market is strong. It was quoted yesterday at £92 for spot, an advance of £1 over the preceding day. Export up to and including the 10th totaled 990 tons.

The base price of sheet-zinc is unchanged (February 10) at 24c. carload lots, f.o.b. mill, 8% off for cash.

LEAD

The expected advance in the A. S. & R. Co. quotation for lead at New York came late on the afternoon of February 9, when the price was put up $3 per ton, or to 6.25c. per lb. (from 6.10c.) The advance was no surprise to anyone, in view of the fact that the independents had been getting premiums for the metal, especially where sales for export were made. Both the domestic and foreign demand has been good. The St. Louis quotation, following the advance, went up to 6.17½c., a figure which the outsiders shaded a couple of points. Lead is rapidly approaching the situation which exists in copper, and should the heavy demand be sustained it will not be long before a shortage will develop. The London supply is none too large. Exports this month up to and including the 10th totaled 3121 tons.

TIN

The quotation for spot tin has not varied far from 41.25c. this week, in a market that has been quiet and easy. Buyers are well covered, at least for the near future, and this fact, with the large arrivals and easy market at London, makes conditions dull. Up to and including the 10th, 2455 tons arrived this month, and there was afloat on that day 5870 tons. The total visible supply on January 31 was 17,011 tons, against 13,901 tons, on that date of 1915. The Welsh tin-plate mills are working far under their capacity, Great Britain needing the steel for other purposes, consequently there is a surplus of tin for export from England.

The A. S. & R. Co. reports that it has just started its tin smelter at Perth Amboy, N. J., and that three months probably will elapse before any definite results can be announced. Delay in receiving the first shipment of Bolivian concentrate, held up by the failure of the Panama Canal, has hindered operations. The brokers importing Straits tin regard the project most seriously, as they have faith in the outcome of what the A. S. & R. Co. undertakes.

ANTIMONY

Prompt Chinese and Japanese grades are scarce, and quotations range from 43.50 to 45c., duty paid. The British antimony regulations, similar to those prevailing in tin, are now effective, and antimony which arrives in British ships and consigned to the British Consul is not released until the dealer who seeks to get the metal gives a guarantee from the ultimate consumer.

ALUMINUM

The demand has quickened and quotations are higher at 55 to 58c. for No. 1 virgin aluminum, 98 to 99% pure.

EDITORIAL

T. A. RICKARD, Editor

OBREGON is reported to have been married at Hermosillo and General Carranza is said to have given him away on that auspicious occasion. The talk of friction between them, is thus negatived. We note also that the increased taxes on mining property must be paid until the end of July, by which time it is to be hoped that more genial conditions will supervene both in the political and fiscal departments of Mexican administration.

WITH the completion of the 18 sections of the mill, the Inspiration Consolidated Copper Company will be treating 14,000 tons daily by flotation at Miami, Arizona. As one of the pleasant features of flotation plants is that they exceed their estimated capacity, it is expected that 15,000 tons will be treated daily in this mill, making it the largest copper-flotation plant in America. The metallurgical extraction is not nearly so complete as at Anaconda because a part of the ore subjected to flotation at Miami is oxidized. Published statements give the recovery as 83 per cent.

SEVERAL months ago we hazarded the opinion that the prices of the chief base metals would continue to benefit from the intensified demand created by the War, and that when hostilities ceased there would come a supplementary demand for the work of reconstruction and rehabilitation in the countries devastated by warfare. We note with satisfaction that an authority so likely to be well informed as Mr. John D. Ryan, the president of the Anaconda Copper Mining Company, has stated recently that it is the belief of himself and his co-directors that "during the continuance of the War, the consumption [of copper] will at least maintain its present level, and that peace in Europe will bring an enormous demand for copper in all the countries now at war, to replace depleted stocks and restore industries in which the metal is indispensable." It is said that while the German Chancellor was asserting that the supplies of copper in Germany were ample, his speech was nearly drowned by the noise made by workmen engaged in removing the copper roofing of the Reichstag. This, of course, is apocryphal, but many a true word is said in jest. There is the other story that German purchases of copper in large amount have been made in New York during the past six months with a view to storage until shipment becomes possible. As to that also we do not know, but such action would be quite in accord with German foresight. The Japanese also are reported to be storing copper. It does seem highly probable, almost certain, that the withdrawal of copper from necessary use and the destruction of metal during the War, whether in ships, machinery, munitions, or utensils, will require to be replaced, while at the same time the resumption of industry will renew a large part of the normal consumption.

EVIDENTLY the recent meeting of the American Institute of Mining Engineers at New York was most successful, thanks in large measure to Mr. D. H. Browne, the chairman of the local section, who made arrangements that promoted better acquaintance and good fellowship among those in attendance. Mr. W. L. Saunders, in retiring from the presidency, was able to announce a gain of 546 in membership, bringing the total to 5221. He spoke with pardonable pride concerning the co-operation of the Institute with the Naval Consulting Board to which it contributed two members, the president and an ex-president, Mr. Ben. B. Thayer. This innovation has proved so successful as to cause the Government to ask the Institute to nominate a member from each state in the Union to collaborate with the representatives of other engineering societies in a campaign of industrial preparedness. The new president of the Institute, Mr. L. D. Ricketts, is on a professional journey to South America, so he was not able to accept his honorable responsibilities in person, but that did not prevent a general expression of satisfaction that he should have succeeded to the titular leadership of the profession in America.

DURING recent weeks we have been glad to record the increase in wages granted to miners in the West. Some of these concessions, consequent upon the greater gains being won by the mining companies, have been in the form of bonuses, a method suggesting unusual conditions and recognizing the possibly ephemeral character of the high metal-prices now obtainable; but, whatever their form, they represent a wise, because just, policy on the part of the mine and smelter managers. Last week our news columns recorded the profit-sharing bonus distributed to employees of the principal group of mines at Kellogg, Idaho. This is arranged on a sliding scale based on the price of lead at 5 cents per pound and going up to a price of 6 cents, the maximum bonus or increased wages being 75 cents per shift. We note that the Federal Mining & Smelting Company promises a dollar extra when lead is above $6.50 per hundred pounds, but this savors of the theatrical, for $6.50 is a highly improbable quotation, having regard to the fact that the price of lead is fixed largely by the Guggenheim group, which controls the Federal company. However,

we smile when we say it. Our readers will be interested to see a comparison between the copper and lead schedules:

Copper		Lead	
Metal price, Cents.	Labor bonus, Cents.	Metal price, Cents.	Labor bonus, Cents.
15–17	25	5–5½	25
17–20	50	5½–6	50
Over 20	75	Over 6	75

The average price of lead during the last 30 years has been 4.22 cents at New York, as compared with an average price of 13.84 cents for copper during the same period. Thus the Butte base is 8.4% above the average price of copper, and the corresponding lead base would be 4.57 at Kellogg or 5.86 at New York. The 17-cent basis for copper would correspond with lead at 5.18 cents, which would require a New York quotation of 7.08 cents. In short, the lead miners in the Coeur d'Alene start 10% better than their comrades at Butte, but it is fair to add that the prospects of bonuses based on rising prices of metal are more favorable for the men digging copper than those digging lead ore. Moreover, the bonuses to the latter apply to all the workers, while those in Montana are variously distributed among the different kinds of employment. These, however, are petty details; the point that we desire to emphasize is the good sense of the mining companies in recognizing the propriety and fairness of giving their employees some share of the abnormal profits they are making just now. Whether at Butte or Kellogg, in California or Arizona, the increased payment to miners has been made, not as a belated concession, but as a frank acknowledgment of the fact that the higher cost of living and the booming metal markets alike justify a higher pay to employees. We trust that the idea will be applied to the members of the technical staffs also. It is a rank fallacy to assume that manual labor is the only kind of work worthy of consideration in times like these.

Pyritic Copper Deposits

Current technical literature has been enriched by a paper on 'The Pyritic Copper Deposits of Kyshtim, Russia,' by Mr. A. W. Stickney, appearing in *Economic Geology*. Profitable mining in that part of the Ural region is based upon the exploitation of pyritic copper orebodies in a belt of schist resulting from the metamorphism of a basic igneous rock, intrusive among Devonian sediments, also highly metamorphosed, and appearing now as limestone, schist, and quartzite. This complex series of older rocks has been further modified by more recent intrusions of peridotite or pyroxenite, now largely altered to serpentine, itself also foliated. All these are cut by dikes, which, however, are nowhere found in association with the pyritic orebodies, themselves confined to one of the belts of uralite-schist where that rock has been changed to a highly fissile chlorite- and epidote-schist. The orebodies are found in series, arranged *en echelon*, with intervals of one-fourth to two miles separating them. It would not be unreasonable to regard this longitudinal succession of orebodies in the schist as a lode eight miles long. In depth, as far as yet ascertained, the masses of ore become narrower and appear to be shortened, as is not unusual in this type of deposit. The largest orebody has been exposed for a maximum width of 90 feet, a depth of 400 feet, and a length of 1500 feet. A bore-hole has proved it to 920 feet deep. The ore consists of a homogeneous mass of granular pyrite, containing 38% iron, 2.5% zinc, 3.5% copper, 0.12 oz. gold and 1.2 oz. silver per ton. Mr. Stickney has made clear the changes occurring between the outcrop and the primary sulphide ore, and emphasizes the relation of these to the level of groundwater. The gossan ends just short of this level and the primary sulphides do not appear until 25 to 95 feet lower. A remarkable feature is the baritic sand, consisting of loose grains of barite and quartz, stained by limonite; this sand has been leached of its copper, zinc, sulphur, and nearly all its iron, and forms a zone between the true gossan and the loose impoverished sulphides capping the primary ore. These impoverished sulphides appear as an incoherent aggregate of pyritic grains, with grains of barite and quartz, increasing in richness with copper in the approach to the primary ore. It is noteworthy that the impoverished sulphides persist slightly deeper along the walls of the lode than in the medial portion of the orebodies. In the unaltered ore the massive pyrite near the walls of the lode carries most copper, zinc, gold, and silver; and the longitudinal extremities of the orebodies likewise show a concentration of valuable contents. All of these observations are highly suggestive. The gold maintains a definite ratio to the barite and in this respect reminds us of the ore-shoots of pyritic copper in the Red Mountain district of Colorado. No defined zone of secondary-sulphide enrichment by descending water is evident. Apparently the rate of denudation caused the groundwater-level to be depressed so fast that the oxygenated surface-water was unable to create economically important secondary enrichments by dissolving at a higher level and precipitating at a lower level; instead, the copper sulphate became diffused in the body of groundwater and into the relatively permeable wall-rock enclosing the lode. Such secondary enrichments as Mr. Stickney records have the form of veinlets and film-like coatings of sooty chalcocite and covellite. These, however, are significant by their insignificance. We commend this study of Kyshtim to mining engineers as the work of a careful observer. We are reminded thereby of the paper by Mr. A. M. Finlayson in the June 1910 issue of *Economic Geology* and of the second paper by the same author in the transactions of the Institution of Mining and Metallurgy. In both of these papers Mr. Finlayson described the significance of secondary enrichment on the famous masses of pyrite in the Rio Tinto mines, in the province of Huelva, Spain. He showed that in this case the economic value of the orebodies was due directly to secondary processes, without which the pyrite would have been too poor in copper to be mined for that

metal. The primary ore contains only 1½%, while the average content of that being exploited in 1910 was 2.26%. There appears to be no doubt that the thin zone of enrichment immediately under the gossan was the object of the mining operations conducted by the Romans. In one of the ancient stopes there was found a deposit, about a foot thick, of iron ore overlying solid unaltered pyrite, indicating the rate of oxidation during the two thousand years that had elapsed since the pyrite had been stripped of its oxidized crust. As the workings at Rio Tinto are deepened the content of the secondary and of the primary ore decreases until the pyrite becomes valuable only as a source of sulphur. Another interesting example is afforded by the gossan outcrops of cupriferous pyrite in the Urals, described by Mr. H. W. Turner in the *Mining Magazine* of November 1912. Mr. Turner shows how limonite outcrops, mined in the first instance as a source of iron ore, were then exploited for their gold, by cyanidation of the silicious ironstone, and finally were proved in depth to be chiefly valuable for their copper. At Kyshtim, as at Rio Tinto, the paragenesis of the sulphides, that is, their order of original deposition, was pyrite, chalcopyrite, blende, and galena, exhibiting a sequence that has been proved in the laboratory to follow their relative solubility. The distribution of the ore and the shape of the orebody have been determined by the nature of the fracture along which the mineral solutions have circulated and the permeability of the wall-rock. The leaching of the latter has enlarged the orebody, sometimes to a lowering of its average contents, but apparently aiding the deposition of the precious metals, with quartz. In these mines, when once well opened to the drainage from surface, the presence of copper in the mine-water to the extent of economic value, as at Kalata, and as at Butte, suggests a process complementary to that by which they were formed, just as the acid-leaching methods simulate other natural reactions. Nevertheless there remains a curious discrepancy between the formulae of the metallurgist and those of the economic geologist, proving that there are many dark places yet to be illumined in this branch of geology.

Anaconda

In this issue we publish another of the series of articles by Professor Austin on the Washoe reduction works of the Anaconda Copper Mining Company. All Americans are proud of this plant as an expression of commercial enterprise and metallurgical progressiveness. Assuredly the editor of a technical periodical is apt to say kind things about it, not only because they would be true but because the management has been singularly generous in giving information useful to the profession, while, of course, always reserving the right to withhold details such as it may be undesirable, for business reasons, to publish. These necessary reservations, however, have not served to impose any serious embargo on knowledge. In consequence, a great deal of suggestive and instructive technical information has been forthcoming, from time to time, from this great metallurgical centre. The goodwill manifested has been further emphasized by the personal courtesy and mental hospitality accorded to properly accredited visitors. Metallurgical students and teachers—for the latter must also be the former—who have visited Montana, whether from New York or London, Berlin or Tokio, will have grateful memories of their visits to Anaconda, as the establishment above all others where they were permitted to enrich themselves by collecting up-to-date information on the concentration and smelting of copper ores. We envy Mr. E. P. Mathewson, the resident manager, the friends he must have made in many countries during the 14 years of his association with the Washoe works.

In 1915 the Anaconda smelter turned out 254,800,000 pounds, equal to 127,400 short tons of blister copper, say, about 126,300 tons of refined copper, from the treatment of 4¼ million tons of ore. This output compares with 225,400,000 pounds in 1914 and 272,300,000 pounds in 1913. The year just ended was important to the Anaconda because in 1915 this company succeeded to the assets of the Amalgamated Copper Company, and thereby took first rank among the industrial enterprises of North America. During the same period the company also extended its operations outside the United States in the form of exploratory work in Chile, under the name of the Andes Exploration Company, which is reported to have opened up 75,000,000 tons of copper ore in the Potrerillos mine. Previously, in 1906, the Anaconda company had acquired a large interest in the Greene Cananea copper mines, which are just over the American border in the Mexican state of Sonora. Another important feature of 1915 was the beginning of a large zinc reduction plant at Great Falls, where operations involving leaching and electrolytic precipitation are to be conducted on a scale of 6,000,000 pounds monthly, equal to 35,000 tons of spelter per annum. This plant is expected to cost $2,000,000 and to be completed by September next.

The descriptive articles of Professor Austin indicate three principal lines of development. The first is the burning of coal-dust in reverberatory furnaces, accompanied by longitudinal charging. For this purpose the coal is dried to less than 1% moisture and then finely pulverized by rolls, before being passed to a burner susceptible of delicate adjustment and control. At the burner it is mixed with the proportion of air required to effect efficient combustion, resulting in a high temperature at the point where it is most needed. The burning of this kind of fuel resembles that of producer-gas. With the introduction of coal-dust as a fuel the blast-furnace, in which department Anaconda has done wonders, has been superseded by the reverberatory. The old furnaces of this type have been enlarged and remodeled to enormous dimensions, being now 23 by 143 feet inside, and from 8¼ feet high at the back to 5½ feet high at the skimming-end, giving a capacity of 700 tons per day when burning 100 tons of coal-dust. Longitudinal hoppers permit of banking the charge and ex-

posing a maximum surface to the action of the hot gases, while protecting the walls of the furnace from corrosive action. Formerly the furnace would smelt 4½ tons of ore per ton of lump coal; now it treats as much as 7½ tons per ton of coal-dust. This enlargement of capacity has met the need created by the making of a continually increasing quantity of fine concentrate, due to the success of the flotation process. So long as the smelting was done in the blast-furnace, it was obvious that the adoption of flotation would yield an unsuitable product, which had to be sintered, agglomerated, or briquetted in order to render it fit for the passage of the draft essential to blast-furnace smelting. Undoubtedly the extending use of flotation and the consequent production of a steadily increasing proportion of fine-grained concentrate will have a powerful effect on the development of smelting, as has been anticipated apparently by the wide-awake staff at Anaconda.

In regard to flotation, the first experiments with this process at Anaconda were made in 1913 and the first trial plant was erected in 1914. At the present time 11,100 tons of copper ore is being treated daily by flotation, and within a month an additional 1000 tons of dump-slime will be treated, besides 300 tons of slime at Great Falls. This refers to copper ore only; to it must be added the zinc ore being subjected to flotation. Of this 100 tons is being treated and a concentrator to treat 2000 tons more is being erected, so that the grand total undergoing flotation treatment will shortly be 14,400 tons daily. In our issue of August 28 we published an article by Mr. Mathewson himself describing the flotation equipment, and Mr. Austin in his second article gives further details, including a flow-sheet, which will be studied with keen interest. Formerly the tailing from the wet-concentration mill assayed about 0.62% copper; now the residue assays only 0.15%, that is, out of the 60 pounds of copper per ton of ore only 3 pounds goes to waste, as against 12.4 pounds formerly. The recovery by milling therefore is 95%.

The flotation concentrate is drained by Oliver filters before passing to the roasters, which have been developed from well-known types of furnace, the latest modification being the Wedge-McDougall, which combines the best features of two familiar designs. Each of the seven super-imposed hearths is 25 feet in diameter, these being rabbled by water-cooled arms radiating from a central shaft. From these furnaces the calcine goes to the reverberatories, fired by coal-dust, as already described.

Another salient feature is the zinc plant. Butte is becoming an important source of spelter, the Butte & Superior Copper Company being one of the leading zinc producers of the country despite its name, which now merely records the metal it was originally intended to exploit. Anaconda is up to date in this respect also, that is, the Washoe works provide for the treatment of zinc ore. At present only 100 tons of such ore is being treated daily, but a flotation concentrator to treat 2000 tons daily is being erected. The original small unit was started for experimental purposes, to discover a practical method of extracting the zinc from the concentrate, by leaching and electrolytic precipitation. This has been successfully elaborated by Messrs. Laist and Frick, as mentioned in our issue of December 25. Gentle roasting of the zinc ore is followed by leaching with dilute sulphuric acid, made on the premises. Impurities in the resulting solution are eliminated by precipitating the iron by means of limestone, and doing the same to the copper and cadmium by means of zinc. The purified solution of zinc sulphate is electrolized, using insoluble lead for the anode and either aluminum or starting sheets of zinc—stripped from deposition on aluminum—as the cathode. This experimental work, on a scale of 10 tons of zinc daily, has been so successful as to justify the erection of a big plant, on similar lines, at Great Falls, as already mentioned. Needless to say this new departure is of the greatest significance, for it means the discarding of the old distillation process of smelting zinc, with its small units in the shape of retorts and its relatively impure metallic product. Thus in the coal-dust firing of reverberatories, in the prompt recognition of the usefulness of the flotation process, and in the development of a wet method of zinc extraction, the Anaconda staff has shown all the initiative and resourcefulness that has given it honorable fame in the world of technology. It remains to add that normally 3200 men are employed, at a monthly pay-roll of $400,000, to treat 16,000 tons of ore per day, the net recovery being about 90%. Besides the copper and zinc, the plant yields 12,000,000 ounces of silver and $1,500,000 in gold as by-products.

What such metallurgical resourcefulness will accomplish is indicated further in the annual report of Mr. John D. Ryan, the president of the company. He states that by reason of the improvements made during the past year the company will be enabled to increase its annual production of copper by 55,000,000 pounds "without increasing the tonnage or grade of ore that has been mined in the past." We give this deeply significant and most interesting statement in Mr. Ryan's own words. Further he states that "approximately 40,000,000 pounds of this increased production will be made without adding to the cost per ton of ore treated." The more experienced metallurgists and engineers will appreciate with what proper pride such an assertion must be made. This 40 million pounds of copper is equivalent roughly to the annual output of such splendid mines as the Miami, the Braden, or the United Verde. The slight increase in the cost of concentration at Anaconda, due to the interposition of flotation in the general scheme of treatment, will be offset by a decrease in the cost of smelting, so that the additional yield of copper will be 'on velvet.' The amount of metal thus won will represent a profit that under previous conditions could have been secured only by increasing the tonnage mined by nearly 50%. This is a magnificent achievement. It gives us keen pleasure to record it, and to express the hope that good luck may be joined to skill in bringing the plans of the management to complete fruition.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mill-Men's Mistakes

The Editor:

Sir—The mistakes of mill-men, when they occur, sometimes prove costly and should serve as a warning to others who might err in the same way. While I believe that not many mill-men would make the mistake I am about to record, yet there are a few who seem to believe in a liberal use of potassium cyanide in the ordinary free-gold amalgamation in a stamp-mill. To these the following incident may be useful and instructive:

I was once called to investigate a case where a 10-stamp mill was being run on free-gold ore, without any concentration after the plates. The ore assayed $10 per ton, and the tailing around $1, showing apparently a good percentage of saving, but the bullion won did not check this estimate by a considerable amount. It looked as though the mill-man was allowing some of it to stick to his fingers, yet the superintendent was loath to believe this, though he could not otherwise account for the discrepancy in the yield of bullion.

A friendly interview with the mill-man revealed the fact that he was using potassium cyanide in the mortar and on the apron-plates, apparently on the principle that if a little was good, more would be correspondingly better. In fact he was feeding it in the mortar in pieces as large as a man's two fingers every half-hour. As a result, he was cyaniding so much of the gold that his reputation for honesty was being dissolved as well as part of the gold. The latter, being in solution, escaped sampling of the tailing, and so the source of the loss had not been discovered.

We gathered all the cyanide in the mill, locked it up, and proceeded to demonstrate that the mill could be run without any at all, even as a wash for the plates. This seemed impossible to the mill-man, but when the bullion began materializing to the right amount, he was compelled to admit that it could be done. His reputation for honesty was also saved, which seemed to please him most. During the remainder of the season's run, the bullion continued to check all right; in fact, the superintendent stated that he had never known a case where it checked so closely with the assays, and it had been demonstrated that it could be done without the use of cyanide. In this case cyanide had proved an expensive method of keeping the plates bright and clean. As most mill-men know, and the rest should know, its continued use will make the plates so hard that they will not absorb and hold the mercury properly, to say nothing of the solvent effect upon the gold and silver-plating on the plates as well. Some years ago I tested the results of its use, by dividing a plain copper apron-plate lengthwise, by means of a wooden strip, using cyanide solution for dressing one side of the plate, and none on the other side. The results, after a run of two weeks showed a marked difference. On the side on which cyanide was used, the copper oxide persisted in showing through the mercury, except for a small space near the head of the plate, and but little gold amalgam had formed as a permanent coating. The clean bright appearance of this side of the plate, after having been dressed with the cyanide solution, was soon followed by a reaction of copper oxide that seemed to have been intensified by the cyanide wash, when compared with the other side where none had been used. On this side, the plate was in better condition to hold the mercury, and it had gained a permanent coating of gold amalgam that kept the copper oxide down completely. It had actually saved more gold than the other side, where the cyanide had been used in moderate quantity.

San Francisco, January 31. W. H. Washburn.

Mine Accidents

The Editor:

Sir—In your issue of November 27 I note a letter on 'Mine Accidents.' We have been much interested in this phase of the subject from this angle: Are there any accidents in the mines due to a not-understanding of the orders given? We have quite a number of men working in the mines who cannot speak or readily understand the English language. Does an accident ever occur because the miner did not understand the order given by captain or shift-boss because he (the miner) does not know English? If so, can you give me an idea as to the percentage of such accidents?

Gwinn, Michigan, January 6. S. Adler.

The Editor:

Sir—There are no statistics that precisely emphasize the occurrence of accidents in mines, due to a misunderstanding of the orders given. In the nature of the case, it would seem that if orders serve any purpose at all they must be understood by those who are expected to perform the specific functions regarding which they have been issued. If that were not the case it would obviously be useless to publish and disseminate definite instructions regarding conformity to precisely defined rules

and regulations. There are no conclusive statistics, however, as far as I know, concerning this matter. Coroners' inquests are notoriously superficial and the details are rarely made public. It would require an extended study of the available information to make answer to your inquiry by reference to specific instances of accidents due to ignorance of rules or misunderstanding of orders, chiefly on account of the employee's inability to readily understand the English language. It is not necessary, however, that the employee should be able to fluently converse in English. It is, however, absolutely essential that he should understand in English the usual short orders or definite directions which apply to his own safety and the safeguarding of the mine. Some experiments have been made to develop a concise teaching plan of English, having reference chiefly to the work done and the rules and regulations to be obeyed. Discipline cannot be enforced where there is ignorance of rules and regulations based upon past experience and an intelligent understanding of inherent hazards and safety requirements.

Newark, N. J., January 23. F. L. Hoffman.

Employer and Employee

The Editor:

Sir—In your issue for January 8 you publish an address by John P. Irish on 'The Relation of Employer and Employee.' After reading the address one has the impression that nearly every word of it is true. If you are an employer you sense a halo hovering above your head and remark: "That man knows what he's talking about." If you are a union man you frown, "All very true, but there's something wrong somewhere."

The trouble lies in the fact that Mr. Irish cited a single instance of abuse by unionism and let that stand before his audience as a true example of all organized labor as practised at the present time. He carefully refrains from citing any examples where the employer has abused his power over his employees, although if he read the reports of the California State Labor Commission he would find many. Probably it is to such oversights that he owes his present success?

The speaker was somewhat premature in his statement that unions cannot be reached by process of law. The Wilkes-Barre, Pa., railway is even now suing the union of its employees for $200,000 for damages caused by 'picketing,' the Clayton Act notwithstanding.

It is true that many abuses are perpetrated in the name of organized labor. But are they made better by spreading the impression that all unions are bad? Only bitterness on the one hand and intolerance on the other result from such propaganda. Would it not be far better in speaking of the abuses by unions to mention also some of their good features? Ask any union man who has been sick and unable to support his family for a time, and he will tell you how his 'local' kept his family and himself. Or, if the treasury happened to be depleted, how his fellow-members dug down into their scantily-filled pockets and kept him going until able to work.

It is also true that those who are in power in the various labor organizations often abuse the power invested in them, and for which the organization is more or less rightly blamed. The members are usually aware of the harm done them by their officers, but because they are busy making a living, the changes for the better come slowly and are not generally noticed.

An instance of distrust of union officials may be cited of the Western Federation of Miners. In November 1915, the striking miners at Morenci and Clifton sent out an appeal for help to the 'locals' of the Western Federation. Nearly every 'local' gave generous response. In December the officers of the Federation sent out a resolution to assess every member two dollars to help the same strikers. The resolution was voted down by the 'locals,' because the money was to be handled by the head office, instead of going direct to the strikers. Such a condition cannot exist for long, and a change in this union is already overdue.

A man of Mr. Irish's long experience must certainly know that the responsibility for the controversy between employers and organized labor does not lie wholly with the unions, any more than it does with the employers. Both sides must make concessions and a feeling of mutual understanding cultivated. Since the employer usually has the higher education and broader understanding, this spirit must start from the office. Mutual understanding will be easiest attained by making the employee feel that he has an interest in the firm. Each firm should have a minimum wage—for an employee has no capital or credit to fall back on in time of a non-living wage—and the employer should voluntarily raise wages in proportion to a rise in profits. The sliding-scale system of wages, as used in many American metal mines, is a step in the right direction.

Once the employees attain confidence in the square-dealing of their employer, the unions will exist only as recreation clubs and the walking delegate will die of starvation.

Skidoo, Cal., January 18. A Union Man.

Shrinkage Stoping

The Editor:

Sir—I observe that Professor Sperr credits F. Percy Rolfe with having first employed the term 'shrinkage stoping' to designate overhand stoping, or back-stoping on broken ore, in a paper presented to the Institution of Mining and Metallurgy and published in Bulletin 55, February 11, 1909.

I am of the opinion that this term originated in Western Australia; you will find the term used and the method of working described in a series of articles entitled, 'West Australian Mining Practice,' by E. Davenport Cleland, and published in the Monthly Journal of the Chamber of Mines of Western Australia, February 29, 1908, and in the issue of March 31, 1908, in which latter the method is described at length.

Berkeley, February 19. W. H. Storms.

Mining in Arizona

By Charles F. Willis

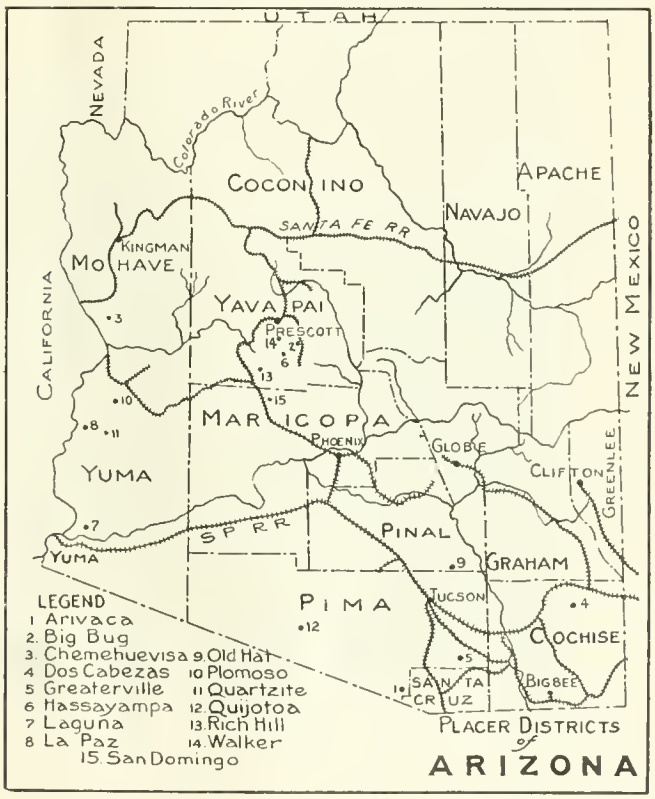
THE chief event has been the settlement of the Clifton-Morenci strike. This strike of 5000 employees, of whom 75% were Mexicans, caused a loss in production of 30,000,000 lb. copper. The main contention was the recognition of the Western Federation of Miners. It was evident that the companies had determined to fight to a finish; fortunately both sides feel that they have won. The high price of copper allows the companies to pay higher wages, which, however, are not greater than they would have been had the men continued work. Much dissatisfaction among the strikers ensued from the losing of this benefit of high copper. They agreed to give up the Western Federation of Miners, although retaining affiliation with the State organization, and returned to work for a period of 15 days, during which time conferences were to be held relative to their grievances. No concessions were made by the companies previous to the men returning to work.

A very few days after the opening of the mines two non-union workers were threatened by union men if they did not secure union cards. This was reported to the company and caused the discharge of the union men, which precipitated a walk-out at the Detroit Copper mines. The fact that this lasted but 24 hours is in itself evidence of the fact that disagreements will be settled by conference. During the time of the strike, the companies maintained what was known as the 'refuge camp' at Duncan, 40 miles from the strike zone, where faithful employees were housed and fed, awaiting the return to work. As negotiations for the settlement of the strike neared an end, one of the principal pleas seemed to be that the 'refugees' be not allowed to return in a body, as it was evident that the strikers did not wish to feel the humiliation. While the companies have undoubtedly gained more points in the strike than the employees, it will probably mean better conditions and a better understanding between employers and employees in the Clifton district.

The general rise in the scale of wages broke all records for Arizona mining, when, with 25-cent copper, the larger companies announced $4.85 per day for shovelers and $5.10 for miners. This was followed by an announcement by Phelps, Dodge & Co. of a general increase of 10% at all their mines.

Interest has been created by the Arizona Venture Corporation's shipment of the so-called wireless-crystals of 'lenzite' to England, from its Waldron mine in the Cedar Valley district, 56 miles south-east of Kingman. This shipment of 400 crystals packed in an ordinary match-box was reported to be valued at $4000. These crystals are said to be superior to any previously used by the British government in its wireless telegraph stations. 'Lenzite' is reported to be an intimate mixture of molybdenite, zincite, stibnite, and other minerals, in such proportion as to make good wireless cohera.

According to the Arizona State Bureau of Mines it is not very generally known that within the boundaries of the State are some of the largest and richest gold placers in the country. The early prospector discovered them, and worked the richest spots with his pan and rocker. Considerable sums of money have been spent



in attempts to develop certain deposits, but through various causes few of these ventures have been profitable. In the exploitation of placer ground the question of an easily available supply of water is important; it is preeminently the great problem in the development of Arizona placers where there is so little rainfall and so few permanent streams.

In 1915 the Copper Queen had one of its largest outputs, despite the fact that during the first few months of the year production was reduced approximately one-third. This was due to the company's inability to recover its stride after the curtailing of production in 1914. In addition, the company produced the largest tonnage of lead ore in its history. A notable change at the Copper Queen is the decrease of oxidized ore and an increase in sulphides. This necessitates changes in the

smelter. Seven McDougall roasters have been added, and experiments in pyritic smelting are being conducted in an effort to take care of the excessive sulphide. Development for the year included 11,637 ft. of drifts and 25,376 ft. of raises, a total of 70,013 ft. No large ore-bodies were discovered, but continuations of known deposits were continuously uncovered. Churn drilling on Sacramento hill has added several million tons of porphyry ore. The output of copper by the Copper Queen and the Calumet & Arizona smelters in Douglas for January amounted to 20,000,000 lb. The Copper Queen produced 12,000,000 lb., an increase over the month previous, while the Calumet & Arizona produced 8,000,000 lb., the same as for December. In this total is included ores received by the Copper Queen from its own mines, the concentrate from the Moctezuma Copper company at Nacozari, Mexico, and custom ores. The output from the C. & A. includes custom ores and the ore from the Shattuck mine.

Increased prosperity is indicated in the gift by the mining companies to the University of Arizona of $100,000, to be applied with the $75,000 appropriated by the legislature for the erection of the Mining Engineering building. The contributions were apportioned according to the annual production of the companies.

After two years of exploration and the spending of $200,000 for development, Young Bros. of the Great Western Copper Co., who have been exploring the Mammoth-Collins gold mine at Schultz, have decided to quit. While much ore was found, it is understood to be too poor to justify milling. The Old Mammoth mine has been known not alone for its gold, but for its excellent specimens of wulfenite. Lessees on the dumps at the Old Mammoth mill have been supplying a large proportion of the wulfenite produced in the United States for two years. It is reported that a representative of the United States Smelting & Refining Co. has been investigating the Mammoth properties.

Oatman is much alive, and now that the proposed merger of the Tom Reed and the United Eastern has definitely failed, the United Eastern will erect a mill with an initial capacity of 200 tons of ore daily, to be the first unit of a larger plant. The Big Jim encountered much water below the 400-ft. level, and, pending the installation of a pumping plant, a drift was run in the foot-wall of the vein recently cut, showing 46 ft. of good ore.

Some interest is being directed to Yavapai county because of its adequate railroad facilities, and mines that made history in the day of Geronimo are being reopened.

The Tucson, Gila Bend & Cornelia railroad is now completed to the Ajo mine of the Calumet & Arizona Co., and train service was started on February 20. This will mean the rapid construction of the 4000-ton leaching-plant to produce commercial electrolytic copper directly. Experiments made during the last two years have evolved the 'Greenway' process of leaching and precipitation for low-grade copper ore.

Tombstone, which has a history typical of the early days of the West, is again active. In 1878 a detachment of United States soldiers were marching from Wickenburg to Fort Huachuca, accompanied by a prospector named Ed. Shieffelin. While crossing the San Pedro valley, Shieffelin took his burros and went into the hills to the east. By day he hid from the Apaches and by night he prospected. Returning to Globe, he showed his samples to a brother and a partner, and they secured a grub-stake. Shieffelin was told of his recklessness in going into the Apache country, and was warned that he would find a tombstone rather than a mine. He did both. In the 80's a heavy influx of water drove the miners from the workings, and for seven years the owners made efforts to develop the properties on an adequate scale. Later most of the larger mines were acquired by the Tombstone Consolidated Copper Co. The early work of this company, a subsidiary of the Development Company of America, was highly profitable, and for many years Tombstone was the big camp of the territory. The Development Co. supplied nearly $2,500,000 to its Tombstone subsidiary in addition to funds realized by the sale of bonds before it came to the end of its resources. Then, with $1,670,000 of its notes protested, and water again in command of the situation, the collateral security for these notes was sold at auction. This caused the downfall of the Development Company of America. Years of litigation ensued and the town of Tombstone, with its wide streets, large business-houses, and neat residences, declined to a population of a few hundred. Finally the mines were offered at bankruptcy sale. On June 23, 1914, when the trustee, Col. A. L. Grow, asked for bids on the property, a profound silence prevailed until in the midst of the large crowd a voice called out, "I bid $500,000." This was Walter Douglas, of the Phelps-Dodge interests, to whom the property was sold. Work was started by Phelps, Dodge & Co. in July 1914. Prospecting proceeded in the upper levels, houses were built, and pumping machinery installed. Dr. Emil Grebe was put in charge; he had been associated with the geological and engineering division of the Copper Queen for years. His slogan seems to be 'Make haste slowly,' for the work is going on consistently and with a constantly increasing number of employees. Four hundred men are now employed, and ore valued at $4 per ton is to be treated. Tombstone has come back.

THE chief sources of accidents in Rand mines in 1914 were as follows:

	Separate accidents.	Persons Killed.	Injured.
Explosives	188	146	167
Falls of rock	451	204	371
Traveling in shafts	61	38	27
Machinery	114	19	95
Various (surface)	193	27	168
Various (underground)	982	174	887
Total	1989	608	1715

Gold-Milling in Amador, California

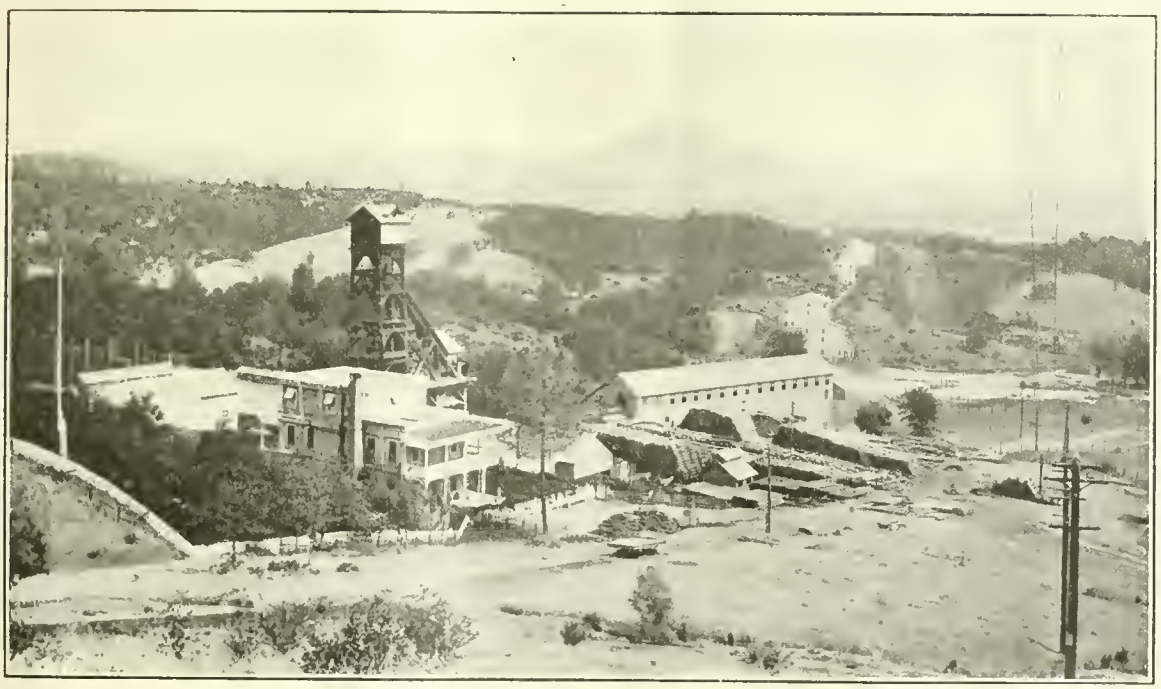
By Edward B. Durham*

INTRODUCTORY. The usual milling process along the Mother Lode in Amador county, briefly stated, is (1) to screen the run-of-mine ore on grizzlies at the head-frame; (2) reduce the coarse ore in a jaw or gyratory crusher; (3) tram the fine from the grizzlies and the product from the crusher to the mill-bins; (4) feed the mixed crushed and fine ore to stamp-batteries, where it is crushed to pass a screen of about 20-mesh (mercury is usually added in the mortar to amalgamate the free gold, but no inside plates are used); (5) pass the pulp over outside amalgamating plates, which catch the amalgam discharged from the battery and any possible free gold; (6) concentrate the sulphides on vanners; (7) sack and ship the concentrate to smelters.

A review of the 'Metallurgy of the California Mother Lode' was given by M. W. von Bernewitz in the MINING AND SCIENTIFIC PRESS of January 3, 1914, covering the process in use at that time at each mill. The present article covers the changes that have occurred since Mr. von Bernewitz wrote. E. S. Pettis has also written on this subject in the issue of September 18, 1915.

THE PLYMOUTH CONSOLIDATED, five miles north of Amador City, is operating the northernmost active mine on the Mother Lode in Amador county. A new mill was erected during 1914 and was described in the PRESS of October 31, 1914, by the designer, Gelasio Caetani of San Francisco. I found the plant operating practically as he described it.

A gyratory crusher at the shaft takes the run-of-mine ore, coarse-crushes it and delivers it to a series of belt-conveyors which deposit it in the mill-bins; from these it goes to 30 stamps and is crushed through a coarse screen at the rate of 300 to 350 tons per day. The stamp product is split by cone classifiers, the coarse is ground in two Hardinge mills and, uniting with the overflow of the cone-classifiers, passes over amalgamating plates. The pulp is then classified, the overflow is treated on 30 vanners and the bottom product is concentrated on two Wilfley tables and their middlings are returned to the Hardinge mills to be re-ground. Mr. Caetani gave a flow-sheet and a detail discussion of the operations in his paper.



THE KENNEDY SHAFT, 100-STAMP MILL, AND TAILING-DISPOSAL PLANT.

The characteristic features of the plant are: (1) the use of the belt-conveyors to carry the crushed ore from the shaft to the mill; elsewhere in this district the ore is moved in cars by man or by mule power; (2) the use of stamps as an intermediate crusher to prepare the ore for the Hardinge mills and the omission of amalgamation in the batteries; (3) the use of classifiers to remove the coarse sand and deliver a uniform pulp to the vanners. The concentrate is shoveled from the boxes at the vanners into an iron car. At the sacking-room, the concentrate is settled in this car by running it over

*Mining engineer, 2227 Ward St., Berkeley, California.

an air-hammer stoping-drill, standing vertically in a pit between the rails and arranged to hammer against the heavy plate on the bottom of the car. The tattoo settles the concentrate and causes the water to rise to the top, whence it is removed.

The Fremont Mine, about two miles north of Amador City, is the next mine south of Plymouth. The milling follows the usual practice of the district, but the tailing from the vanners is re-treated in a separate plant operated by W. E. Darrow and P. T. Hambric. The

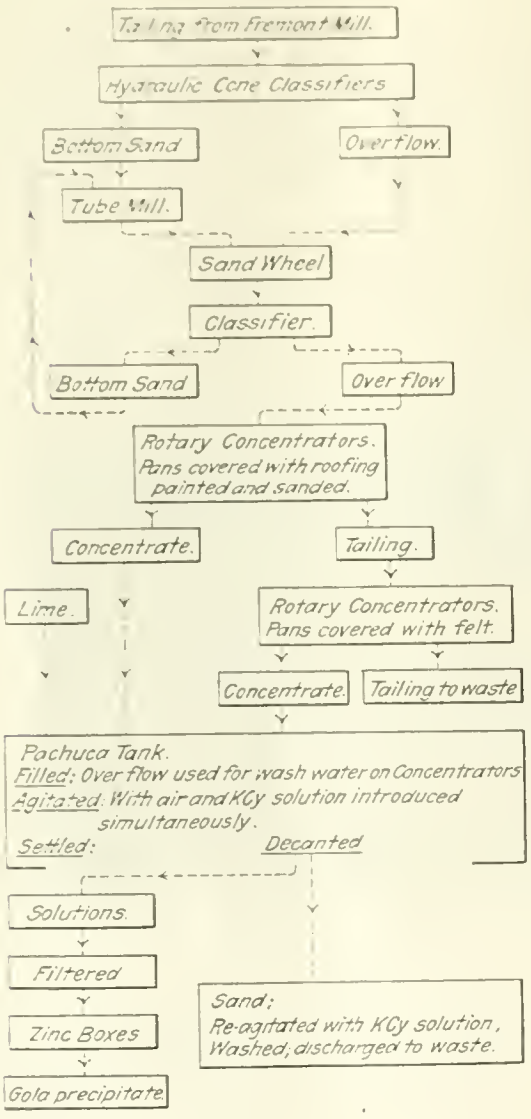


Fig. 1.

principle of their process is shown in the flow-sheet. Fig. 1.

The tube-mill for grinding the coarse portion of the tailing was being installed at the time of my visit and was not an active part of the process. the plant was running with the bottom product of a thickening cone going directly to the first pair of 'rotary' concentrators.

These concentrators consist of tiers of slightly inclined pans held by radial arms from a central shaft. The number of pans in one tier depends on the diameter of the machine, each machine having 10 tiers. The pans are approximately 2 ft. wide by 6 to 8 ft. long, they are rigidly attached to the shaft and slope outward. The shaft with the attached pans revolves slowly; the pulp is fed to the pans during a half revolution; the sand collecting on their surface is washed with clean water during a quarter-revolution, and the concentrate is washed off during the remainder of the revolution. The tailing and the concentrate fall on a cement floor, which is so sloped that each runs to appropriate channels. The pans on the first pair of machines are covered with asphalt roofing-paper, which is painted and sanded; those on the second pair of machines are covered with felt, which catches the coarse sand that escapes the trays on the first machines. The mill-tailing is said to carry gold amounting to about 50 cents per ton and the concentration system builds this up to $5 to $10 per ton. The gold is extracted by cyanidation.

The Bunker Hill Consolidated is working less than a mile north of Amador City. The milling is in accord with local practice. The tailing from the mill goes to a re-treating plant, run by Mr. Darrow, at which the process is said to be different from that used in treating the Fremont tailing; I did not visit it.

The Original Amador Consolidated is operating at Amador City. The old mill was described by Mr. von Bernewitz in the article previously mentioned, in which he noted that the mill was handling 90 tons of ore per day. The mill was re-modeled in the spring of 1915; the new process of milling was briefly described in the Mining and Scientific Press of June 19, 1915, and a complete description with flow-sheet was given by the superintendent, T. S. O'Brien, in the *Engineering and Mining Journal* of August 14, 1915.

The crushed ore is screened in four trommels with ¾-in. openings; the oversize goes to 20 stamps, which discharge through ½ to ⅝-in. openings, depending on the hardness of the ore. (The fine screen is used with the harder ore so as not to overload the Hardinge mills which follow.) The fine ore from the trommels and the discharge from the stamps is classified in two Dorr machines; the coarse sand goes to two Hardinge mills with amalgamating drums attached to their discharge; the ground pulp passes over amalgamating plates to two hydraulic classifiers with three spigots each; the product of each of the six spigots goes to a separate double-decked table made by the Deister Concentrator Co.; the various concentrates are passed over amalgamating plates, de-watered, and transferred to the cyanide plant for further treatment. The overflow from the two Dorr classifiers and from the two hydraulic classifiers below the Hardinge mills goes to a thickening-tank, the overflow of which is used for mill-water and the thick pulp passes to four double-decked Deister slime-tables and their concentrates are united with those from the other tables for cyanide treatment.

The advantage of using some other type of crusher than stamps for the intermediate crushing was apparent, and later I learned that the management proposed to do so. The cyanide plant is described in Mr. O'Brien's article but was not visited by me. The re-modeled mill

is expected to handle 300 tons of ore per day. The 20 stamps are the same as in the old mill where only 90 tons of ore was crushed per day.

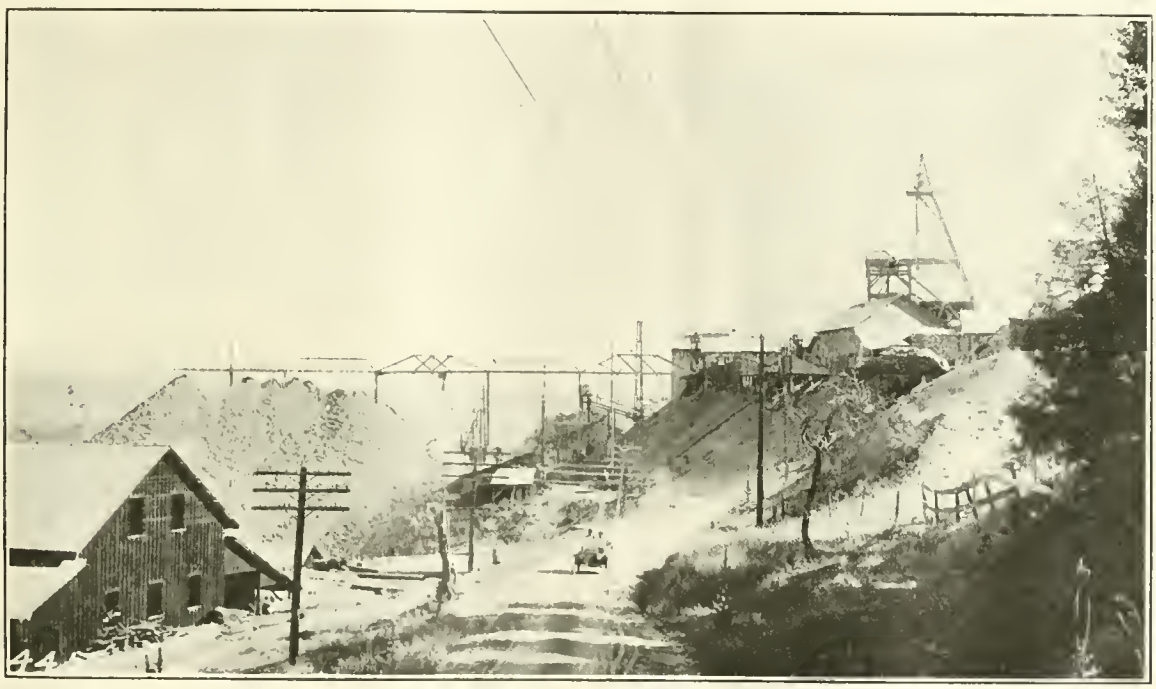
The Keystone Mine is also situated at Amador City. The run-of-mine ore is dumped on a grizzly; the undersize is treated at the 'old mill' by 20 light stamps; the oversize is crushed in a gyratory crusher and is treated in the 'new mill' by 20 heavy stamps. In both mills, the stamps are followed by amalgamation and the collection of the sulphides on vanners, as is usual in this district.

The Central Eureka is the next active mine to the south, along the Mother Lode. It is about midway between Sutter creek and Martell. The mill has 40 stamps and 16 vanners, but only half of the equipment is in use. The process is the one customary in this district. The tailing from the mill is carried across the main road in a flume on a high trestle and impounded in a ravine where it cannot get into the streams.

The South Eureka property lies a little farther south. The milling process is the usual one but the mill is divided into four units of 20 stamps each and their product goes to 12 Frue vanners (each battery supplying three vanners) and each unit of the mill is driven by a 50-hp. motor placed in a separate room back of the ore-bins. The arrangement of the driving machinery and the launders is unusually neat. The mill is well lighted with skylight, is roomy and orderly and presents a pleasing appearance. The tailing is conducted by a flume through the top of an adjacent hill and impounded in a ravine beyond.

The Oneida Mine is situated a little east of Martell; it belongs to the South Eureka Mining Co. The workings of the two mines are connected. The Oneida hoist is being used to raise water by means of two tanks working in balance; it is equipped with flat ropes. The mill is idle.

The Kennedy is over the hill to the south of the Oneida or about ¾ of a mile from Martell and near the road to Jackson. The mill is situated near the East shaft, which is the main opening. It has 100 stamps and the process is the usual one. The tailing is carried across the valley by a flume and then is raised by four sand-wheels in series until it passes over the ridge to a ravine to be impounded; see photograph. The wheels are each housed in a separate building; I estimated them to be 60 ft. in diameter and to have a net lift of about 45 ft. each. The canvas plant mentioned by Mr. von Bernewitz is idle and apparently abandoned. The sulphide concentrate from the vanners is chlorinated in a separate plant, as noted by Mr. von Bernewitz.



THE ARGONAUT MAIN SHAFT.

The Argonaut plant is distributed on both sides of the road leading from Martell to Jackson; see above. The milling process is the usual one, with rock-crushers, stamps, plates, and vanners. The tailing from the vanners is classified, the bottom sand goes to the pond, the overflow is concentrated on a Darrow rotary concentrator about 20 ft. in diameter. The concentrate from this is further concentrated on three vanners. The sulphides collected in this way from the mill-tailing are very fine and the amount appears to be small.

The Zeila Mine to the south-east of Jackson, idle for some time, is now being re-opened by the Kennedy Mining & Milling Company.

Amador county in 1914 had 23 mines producing 630,993 short tons of ore from which $3,082,002 in gold was recovered, an average of $4.87 per ton. Silver content averaged only 2½ cents per ton.

The Washoe Reduction Works, Anaconda—II

The Coarse Concentrator and Flotation Plant

By L. S. Austin

THE concentrator contains 8 units, each of 2000 tons daily capacity, in two buildings, with a power-house between. The power-house, with its engines and boilers, is no longer in operation, steam having been supplanted by electricity, so that individual motor-drives are common throughout the mill.

From the Anaconda classifiers down, the mill is being altered for flotation. Above, the system consists of graded crushing with jig concentration for the removal of coarse concentrates, and a tailing that is progressively crushed, no part of the tailing being wasted, but all of it finally re-crushed for flotation. In the process of concentrating of 2000 tons, 500 tons is removed as coarse concentrate, including all over 1½ mm. and 400 tons overflow, leaving 1100 tons for re-crushing.

Beginning now with the second-class or run-of-mine ore: this comes by the train-load in hopper-bottom cars, just now at the rate of 13,000 tons daily. One car in ten is dropped into hopper-bottom bins at the sampling-mill, where it is crushed coarsely and raised by a big elevator to an overhead belt-conveyor, whence it joins the nine cars that have been directly distributed into the ore-supply bins as indicated on the flow-sheet, Fig. 2.

From the ore-bin a chute with regulating slide delivers onto the perforated feed-shoes, these taking out fine of less than 2-in. size, while a 12 by 24-in. Blake crusher breaks the coarse lumps. These go to 2-in. trommels, the oversize from which is crushed, and then passing over a trommel having inch-holes. This furnishes a product between 2 and 1 in. diameter for a couple of two-compartment Hartz jigs. These yield per day 20 tons of coarse concentrate, 665 tons of middling, and a fine-hutch product of 115 tons going to Hancock jigs in the 'Jig division.' It is the middling that chiefly concerns us: this, after passing over a dewatering screen, is crushed in 54 by 24-in. rolls to yield an undersize for the already mentioned 1-in. round-hole trommel. Here then we have a total product of 2520 tons (more than the original ore) all of which must be screened through four trommels having ⅝-in. holes. These trommels yield an oversize of 800 tons, being all between 1 in. and ⅝ size, for the fine Hartz jigs and an undersize of 1720 tons now going to eight trommels having slotted holes of 1½ by 12 mm. It is the 1020 tons oversize, namely, all between ⅝ in. and 1½ mm. that is treated on the Hancock jigs while the undersize, some 700 tons, goes to the Anaconda classifiers. The Hancock jigs give 185 tons of concentrate, a quantity of middling to be returned to the machine but principally a middling product of 1050 tons. This is dewatered and raised to trommels having 1¼ by 12 mm. slots, yielding an undersize suited to the classifiers, and an oversize of no less than 2100 tons in weight, all of which must be crushed in the 54 by 24-in. rolls until fine enough to go to the classifiers.

Let us now go back to the fine Hartz jigs, which had taken a product 1 to ⅝ inch in size. These jigs yield 45 tons of concentrate; 200 tons of a hutch-product sent to the Hancock jigs, and finally 550 tons of a middling, which, after dewatering, is crushed by 54 by 24-in. rolls, returned to the 1-in. round-hole trommel to travel through the system largely by way of the Hancock jigs.

Finally, at the classifiers, we note that the Wilfley tables, provided with Butchart riffles, remove what concentrate they can, some 250 tons that settles in the dewatering bins, situated, as may be seen on the general plan, immediately below and adjoining the concentrator, and where the other concentrates are unwatered and stored. It is the middling (really tailing) from these tables, some 1100 tons daily, that passes to the flotation system.

One may notice, by the rounded appearance of the coarse concentrate, that it has been subjected to much wear in the operations of crushing, elevating, and jigging. It is sad to think what would happen were the slime, consequent upon this wear, turned over to the tender mercies of water concentration. Oil flotation is indeed its guardian angel.

In 1906, I find by my notes that the output per section was 900 tons. As above stated, it has risen to 2000 tons. This is due in part to the speeding up of the machines, in part to the replacement of 42x15-in. rolls by those of 54x24-in. face.

The treatment of the sand from the Wilfley tables by flotation is described herewith.

Slime Treatment at the Round-Table Plant

The overflow from the Anaconda classifier in the middling division of the concentrator still retained 2 to 2.5% copper, but owing to its fineness (approximating 200-mesh) and to the accompanying colloids, it could not be practically treated by the water-concentration method then employed. Accordingly, in despair it was run to waste, being impounded in slime-ponds on the flat below the works for future possible recovery.

Of all the tables used in the treatment of slime the round table, in which the pulp is spread out in a film and then washed to remove its gangue, has been the most successful. But to treat the large quantity of slime made in this plant it was necessary to use a more compact machine than a singledeck or even a quadrupledeck table. This was accomplished by the use of the

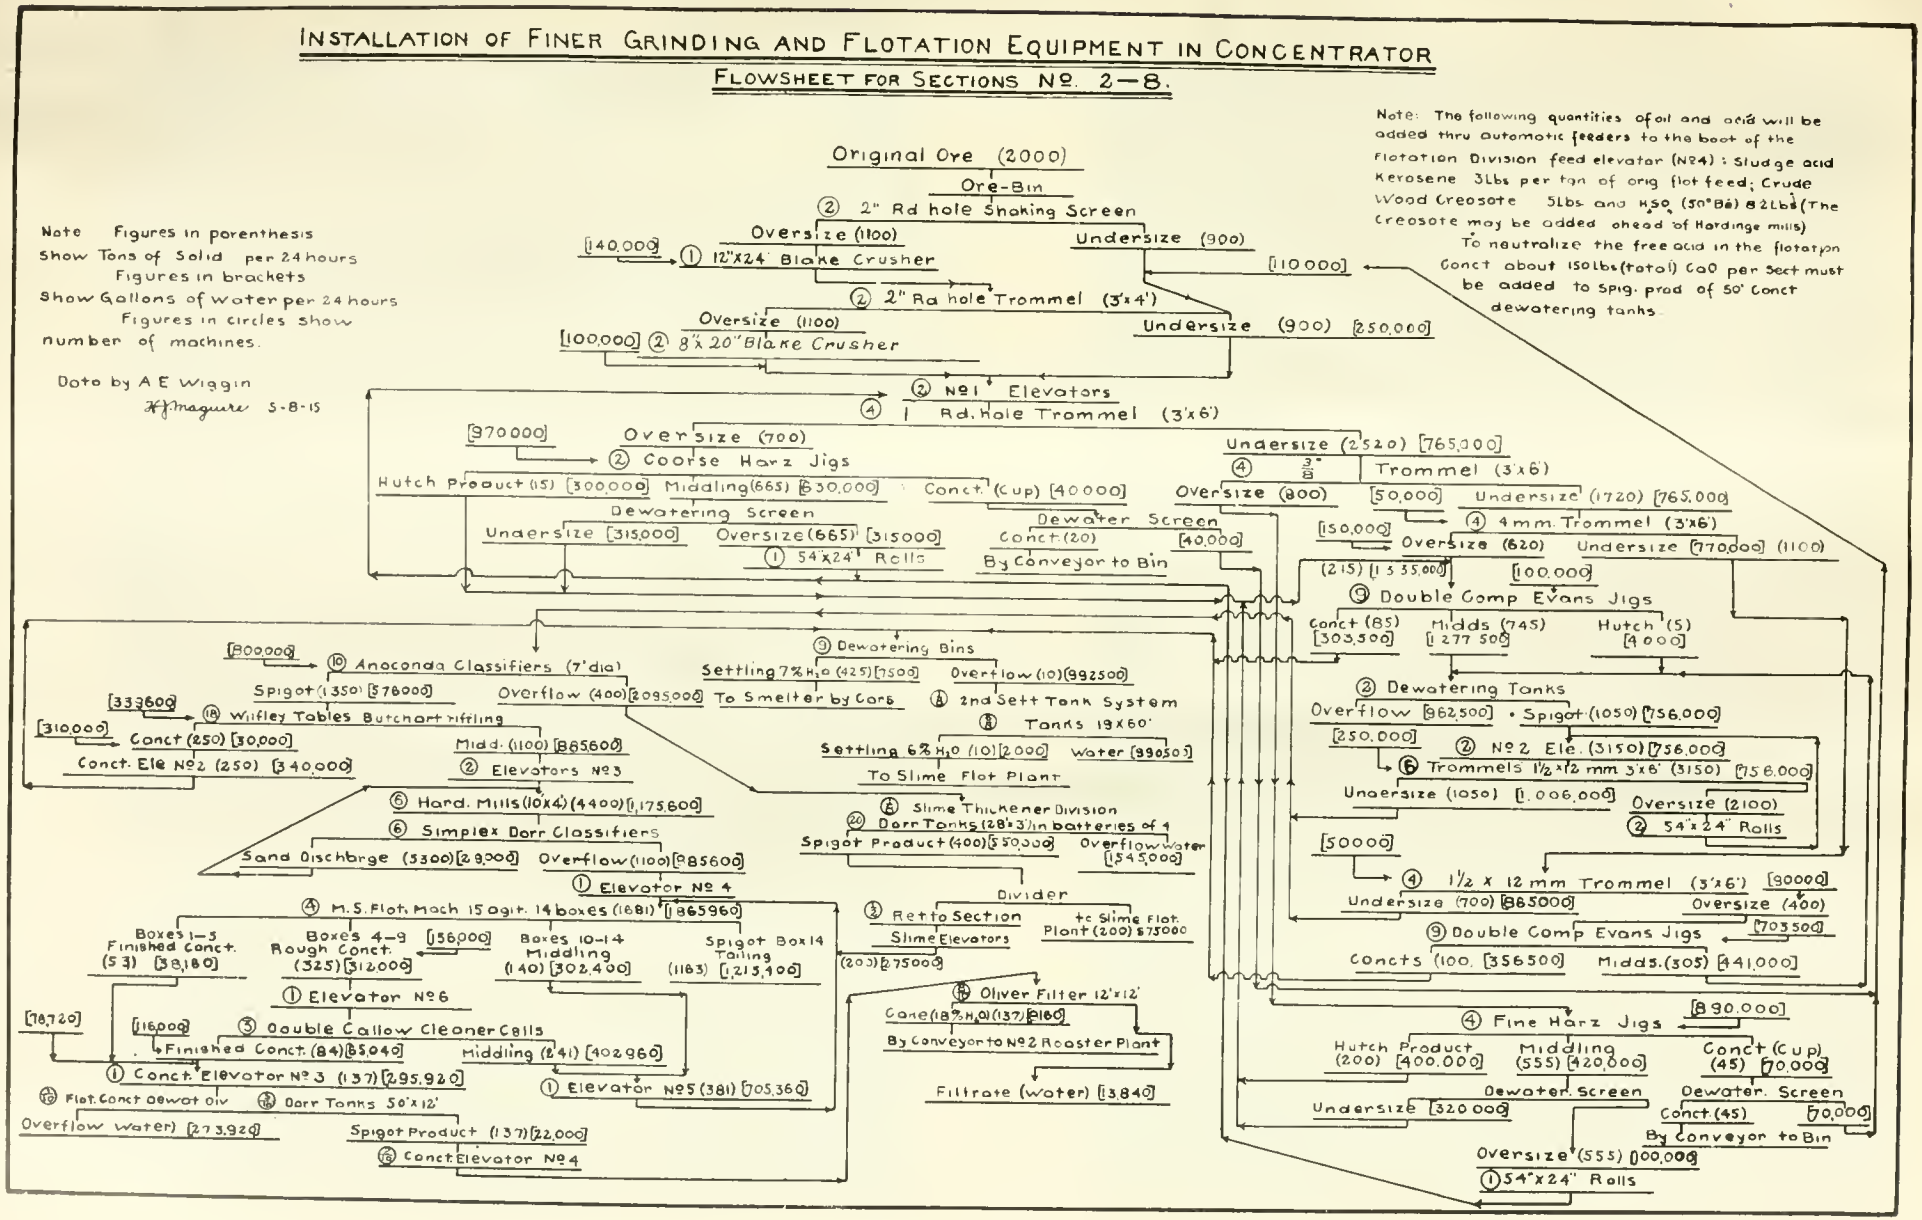


FIG. 2. FLOW-SHEET.

20-deck machines, the decks being 18 ft. diam. Here, in a moderate sized building, could be installed 20 of these machines or 400 decks in all, affording a united area equal to two acres.

The overflow from the Anaconda classifiers has been thinned to 2% solids, due to the use of the hindered-settling water, so that it must be thickened before treatment on the round tables. This is done at the Dorr thickener plant—see the general map, Fig. 1+. The plant contains 160 thickener tanks, each 28 ft. diam. by 3 ft. high. To place so many tanks in a building of reasonable size it was necessary to pile them in tiers four high, each taking its share of the flow from all the mill and giving a thickened underflow of 10% solids suited to round-table work, while from the peripheral overflow launder the nearly clear water runs to waste.

Fig. 4 shows in elevation the round table building, 275 ft. by 57 ft. in area, which receives its feed from the Dorr thickener division. This, delivered to a revolving general distributer at the top of the building, is distributed equally to each of the 20 machines. A similar, but smaller, distributer delivers equally to each of the 20 decks of each machine.

The patented distributer is quite simple and effective. It consists of a circular trough divided by 20 radial partitions, each partition taking off by pipe to one of the 20 machines. The whole launder-flow to the plant discharges into the bent distributing pipe revolving on its axis and spilling into the cells of the annular trough as it revolves. Each 20-deck machine has a similar distributer, also shown in Fig. 5.

The 20-deck machine has no central shaft, but is carried by eight wheels that travel smoothly upon the circular track. Since no central shaft is needed, a central circular opening of 4 ft. diameter is left through each deck. Up and down through them the operator can easily move in order to inspect and regulate the flow of wash-water. The ladder is a square frame with transverse bars for steps and the 20 flows, as well as the clear water, are carried down to the individual decks just outside the ladder-frame. The space is also illuminated by electric light.

The products from the tables are three, each delivered

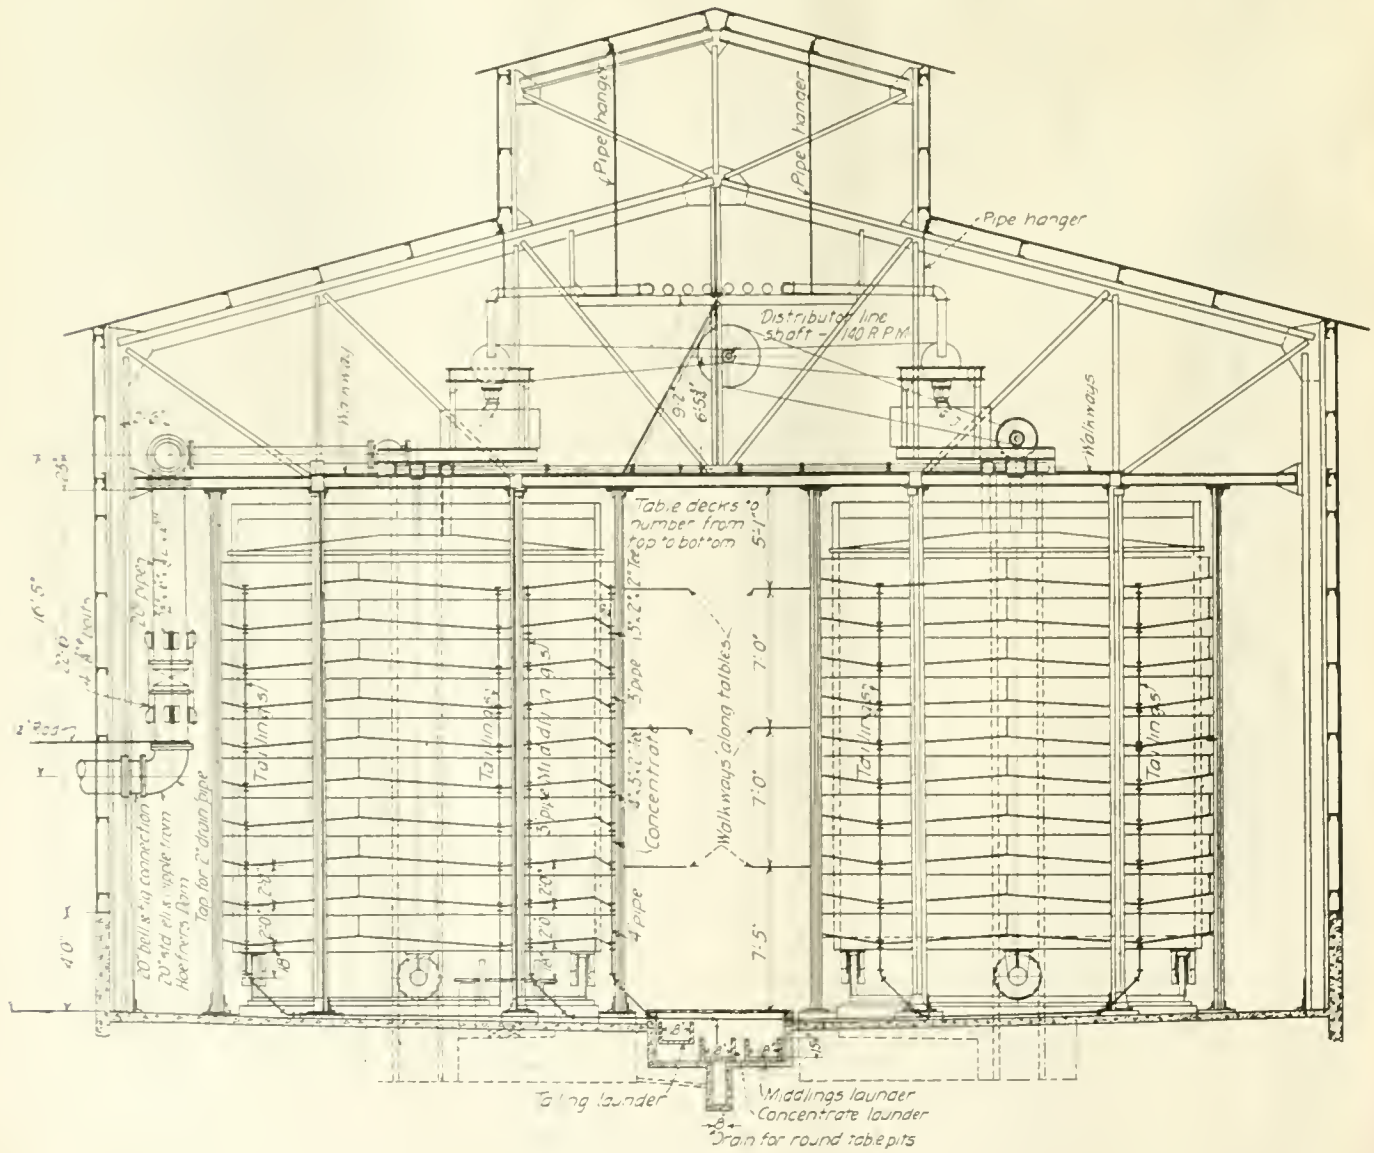

FIG. 4. ROUND-TABLE PLANT.

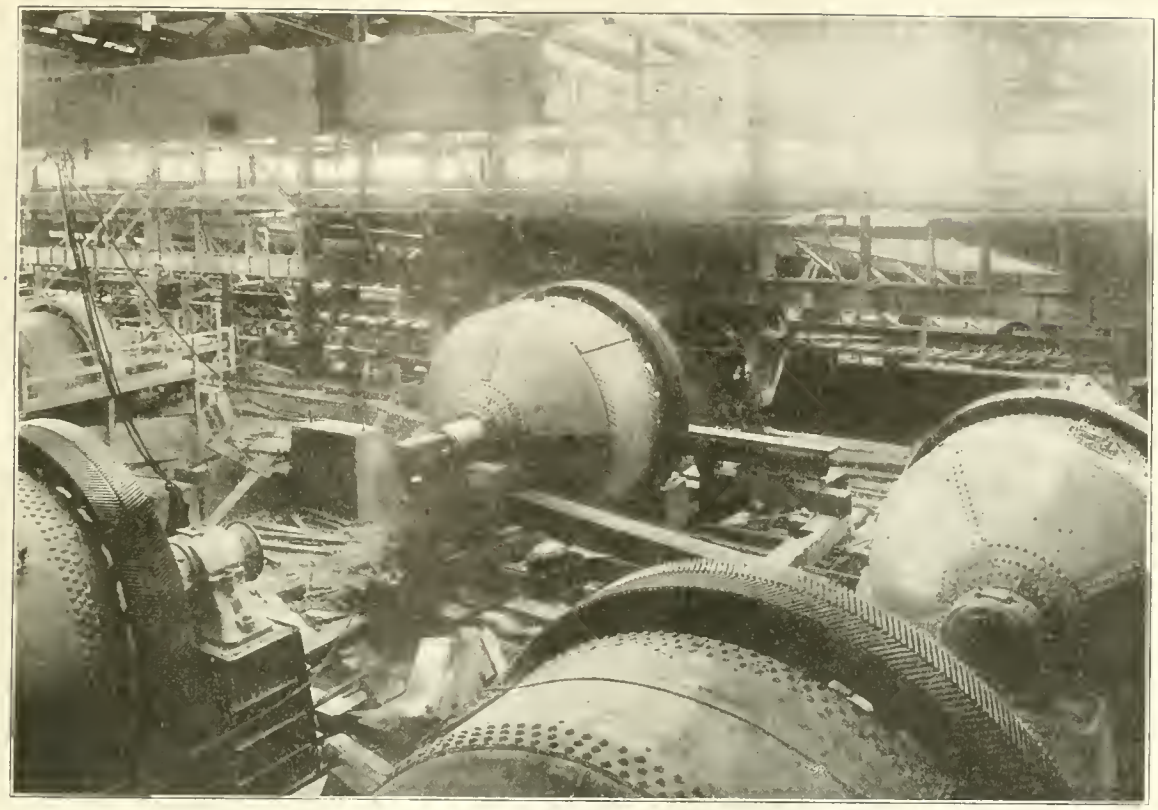

FIG. 6. HARDINGE MILLS, RE-GRINDING DIVISION.

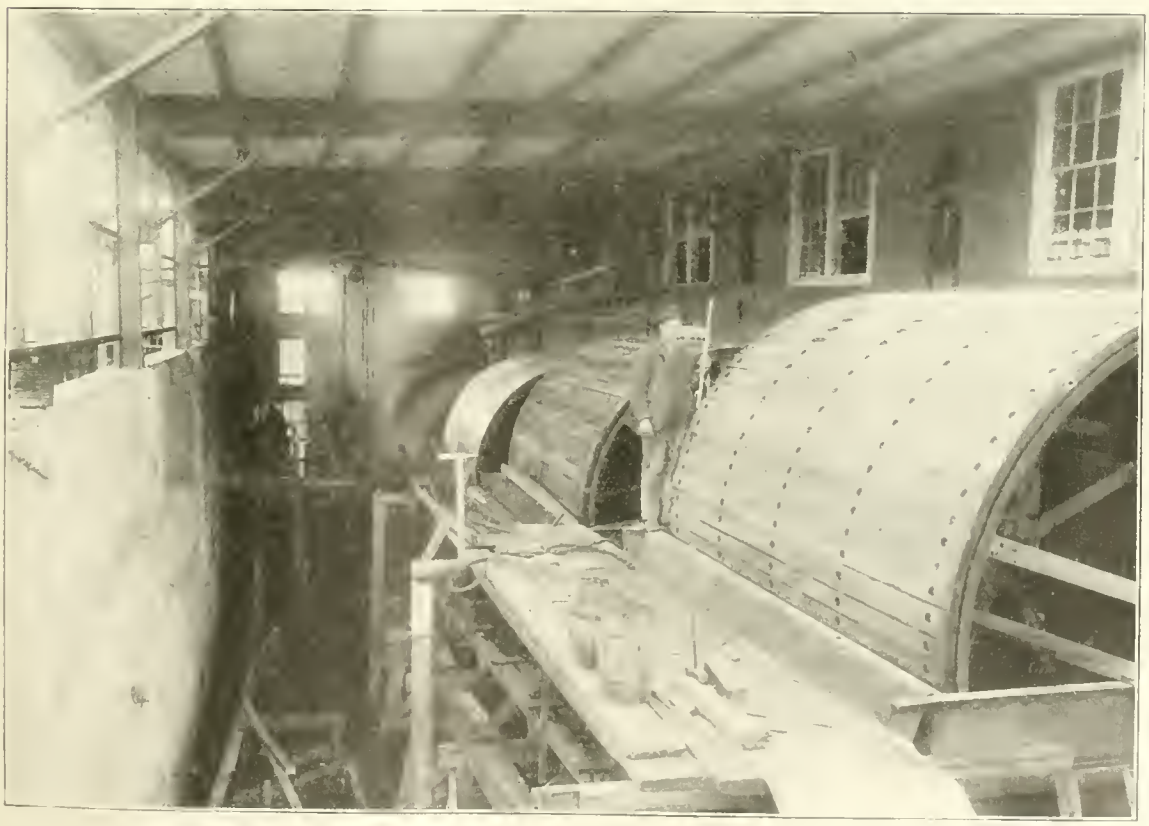

FIG. 7. OLIVER FILTERS. THE CANVAS FILTER-CLOTH HAS NOT BEEN PUT ON THE NEAREST FILTER-DRUM.

to its own launder, namely, concentrate, middling, and tailing. The concentrate is run outside the building to a settling-tank, the middling product is pumped to the feed-launder, the tailing descends by launder to the slime-pond, where it is at present impounded in the hope that it may, some day, pay to re-treat by flotation. The heads or feed to the tables contain 2% copper, the concentrate 7.25% with 55% insoluble, the tailing 1% copper, equivalent to a recovery of 53%.

For particulars of the 20-deck round table, see paper by Messrs. Laist and Wiggin, Trans. A. I. M. E., Vol. XLIX, page 470.

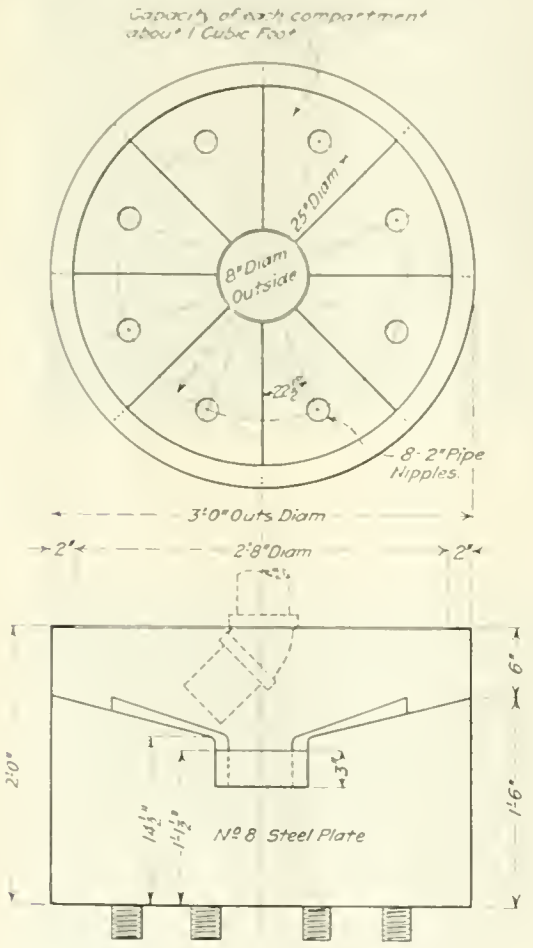

FIG. 5. ROUND-TABLE DISTRIBUTER.

THE FLOTATION PLANT occupies the lower part of the concentrator building, which is being dismantled, unit by unit, and the space thus cleared being replaced by machines for re-grinding and making flotation concentrate.

Adjoining the Dorr thickener plant (see general plan, Fig. 1) is the concentrate-dewatering plant and the Oliver filters, all parts of the flotation system.

In brief, the process consists in finely grinding the concentrator-tailing, adding oil and acid to the pulp, agitating this mechanically (finally with the aid of air), skimming the mineral-bearing froth produced (this being the concentrate), settling it out in Dorr thickeners, and from them removing the thickened underflow for filtration by the Oliver filters. The resultant product, still retaining 10% moisture and containing 6% copper, is sent to the smelter.

On the right-hand bay of the 'middling division' of the concentrator are ten 7 ft. Anaconda classifiers, which take the screened undersize from trommels of 12 by 1.5 mm. opening (Fig. 2). This is really the collected tailing from all the water-concentration operations. It amounts to 1,750 tons, the 250 tons out of the 2000 tons capacity having been already removed as coarse concentrate. Classification gives two products, a slime-overflow of 400 tons of −200 mesh and a spigot-discharge of 1350 tons, which would include all sizes between 1.5 mm. and +200 mesh, and is nearly slime-free. The overflow is now treated on round tables, but these will be eventually discarded in favor of flotation. The spigot-discharge passes to Wilfley tables provided with the curved Butchart riffles and these take out 250 tons of concentrate, leaving 1100 tons of so-called middling.

It is this middling product that has to be finely ground either in tube-mills or in Hardinge mills. These are situated in the 're-grinding division.' (Fig. 6.) One unit is supplied with tube-mills, 8 ft. diam. by 12 ft. long; the other units are to have each six Hardinge mills, 10 ft. diam. with the cylindrical part 4 ft. long and 11 ft. between bearings. The middling product of the Wilfley tables flows by launder directly to these mills.

Alongside and parallel with each mill is a Dorr classifier of the rake type, which receives the flow from the mill, returning the coarser sand for re-grinding, while the classifier-overflow, now sufficiently fine, passes to the agitators. It is a mixture of sizes, mostly below 60-mesh, experience indicating that it is fine enough to have released most of the included grains of copper sulphides. This mixture of sizes down to the finest is regarded as being better than one in which the grains are uniform. It is held that the fine particles fill in spaces between grain and grain, so increasing the film attraction. To each mill is fed a small amount of wood creosote ($\frac{1}{10}$ lb. per ton), and this is ground into the sand as it passes through the mill. A mineral particle, at the instant of fracture, and before it can be in any way oxidized, may be at once filmed with creosote, the oil thus choosing the favorable instant when the freshly-broken nascent surface can receive it. At any rate it has been practically found that this homeopathic dose aids in the subsequent agitation. For grinding, not only pebbles but iron and steel balls have been tried. Local pebbles and those from the Pacific coast have been tested, but the imported selected Danish pebbles have proved to be the most satisfactory in spite of their price. Pebbles of a flattened spheroidal form do not last, since they wear thin and eventually break in two.

The Jeffrey Co. is furnishing a cast manganoid ball of 1 to 3 in. diam. that serves quite well. It is made from any scrap cast-iron, to which has been added ferro-manganese to bring minimum content to 1.5% Mn. Cast in a sand mold, if perchance venting is omitted, then a bubble forms on the top of the sphere, and when the thin scale over the bubble breaks, the remaining depression slowly wears in cup shape. Manganese-steel

balls have also been tried, and owing to their toughness, they are quite durable. As between the various metal balls it is a question of price, or of cost per pound per ton treated. Metal balls as compared with pebbles strike more effective blows. The metal liner is another feature that is being tried. These are of the ribbed type bolted to the shell of the mill. Between the ribs the pebbles or balls are expected to lodge, thus protecting the liners from wear. A type of liner, now being introduced, consists of pieces of 4 to 6 in. long, sawn from 60-pound rails. The cutting of the rails is done with a rapidly-revolving cold saw, which will sever a piece in a few seconds. These pieces are packed on end against the shell of the mill and the interstices filled with cement mortar.

In the tube-mill, at the discharge end, is placed a perforated-plate diaphragm to hold back the pebbles from discharging. In the Hardinge mill, which has no such diaphragm, by reason of selective action, small pebbles (perhaps only sand) escape. Any such pieces, of course, are returned to the feed-end by the Dorr classifier.

Turning to the flow-sheet, it will be seen that the 'flotation division' consists of four Minerals Separation agitators, each of 350 tons capacity. Two machines are placed back to back; the other two are single. Each machine has 14 divisions where the re-ground pulp is treated in series. The Dorr classifier overflow is brought by a distributing launder to the heads of the four machines, a deflector serving to cut out what is needed at each. The pulp, with the addition of 5.5 lb. of 52°B. acid and 2.5 lb. of mineral-oil residue (sludge from the oil-refinery) is agitated in the compartment in series from No. 1 to No. 14. There results at each compartment a froth that is scraped into a launder, while the unaffected tailing is drawn off at the bottom, to enter the feed division of the next compartment. The supply to any compartment is regulated by a flap-valve actuated by a rod with a screwed end and a hand-wheel at the front of the machine.

Referring to the flow-sheet, it will be seen that the darker finished concentrate from the first three boxes or compartments of the M. S. agitators is ready to send away, that the rich middling from boxes No. 4 to 9, inclusive, goes to the Callow machines for further treatment, that the product from boxes No. 10 to 14 (the dirty middling) is to go through the M. S. agitator again, and that the final clean tailing, the spigot-discharge, now containing 0.10 to 0.12% copper can be sent to waste.

The Callow machine aerates the rich middling from the M. S. machines, giving a mass of froth that joins the other concentrate, but the tailing cannot be sent to waste, and this goes back to the primary machine to again go through it in series.

We see then that the M. S. machines give a clean tailing, the Callow machines a clean concentrate. The two machines work in a closed circuit except that there is a point of escape for the tailing in the first one. The Callow machine may be regarded as affecting a further saving of concentrate due to aeration, such as the primary machine will not give.

We now come to the question of how this final bulky and light product is to be collected and brought into solid form for smelting. This is effected at the concentrate-dewatering plant (see the general plan of the works) where are are six 50-ft. Dorr thickening tanks, each 14 ft. high.

In studying the flotation methods of this establishment one must be careful to not become confused by the two buildings interposed between the concentrator and the concentrate-dewatering plant. These two are devoted to other purposes independent of our present study.

If Dorr thickeners of the ordinary type were used, the frothed material, falling at the centre of the tank, would float across to the overflow-launder that encircles the edge of the tank and would be lost in part. To prevent this, a frame 16 ft. square and about 4 ft. high, surrounds the centre, its lower edge dipping into the liquid. This holds back much of the froth. Another diving-board encircles the tank two feet within its edge, also tending to hold back the bulky product while permitting the water to escape at the circular overflow-launder. The froth thickens, gets heavier by standing, and eventually sinks. One may note, though, that it sometimes misbehaves and manages to climb under the skimming edges into the overflow-launder, causing some loss. How to more speedily thicken the material is a practical question. In a vacuum-pan I have seen the contents, when they happen to foam, beaten down by the sudden admission of some air, which at the same time breaks the vacuum.

The pulp has now sunk beneath the water and has been ploughed by the bladed arms of the thickeners, to the centre, to be discharged thence as a thickened product by launder to the Oliver filter-machine. (Fig. 7.) An addition of 125 lb. of quicklime per shift is made here. It flows inside the filter-drum, thence finding its way beneath to the hopper of the machine, where it is kept stirred by an agitator. The reader will remember that this type of machine draws its supply of pulp from the bath of pulp beneath, sucking it against the exterior filter-surface of the revolving drum. By the time the filter-surface begins to rise above the bath it has been coated with a layer of material an inch thick, and this is being sucked drier as the revolution continues. It is not necessary, as in cyanide practice, to wash the layer, since the object in this case is merely to remove the water. When the product has been scraped off on the discharge side, not more than 10% of moisture is left. The moist concentrate of the machine falls upon a conveying-belt to be taken away by hopper-bottom cars to the smelter.

American rock-drills were employed recently in driving two tunnels in Tuscany, Italy. American air-compressors were also used. It will be recalled that power rock-drills were first introduced in America for driving the Hoosac tunnel in Massachusetts, in consequence of the results attained with similar machines in the driving of the Mont Cenis tunnel in the Alps. Then they were introduced in the mines of Colorado.

Clay: Its Effect in Ore-Dressing and Cyanidation

By A. W. Allen

CLAY is indispensable in brick and pottery manufacture, while in the treatment of ore it is generally a nuisance. Some clays in ores are not troublesome, but others greatly hinder filtration. In some cases settlement and dewatering of slime is only possible in highly alkaline or acid solutions. Old slime allows decomposition of pyritic and other minerals associated with clay, resulting in decreased efficiency of the cyanide solution.

There is a distinct difference between colloidal and non-colloidal clay, the former being undesirable when treating ore. The weathering of clay has a marked effect on the physical properties of the mineral. Original clay is practically non-absorbent, but the weathered material is highly absorbent.

In its non-colloidal state it is completely unplastic, whereas after decomposition it becomes highly plastic and capable of intricate manipulation. These alterations during weathering are fully utilized in the ceramic industry, where plasticity is, at times, of considerable importance in the manufacture of chinaware. The retentive or absorption powers of certain clays is well known. Adsorption has been defined as the power that clay possesses of removing, from solutions, substances with which it is in contact.

The adsorption of metallic gold is an improbability when consideration is paid to the fact that the gold-potassium-cyanide compound is dissociated in the presence of water into K ions and $AuCN_2$ ions. If the latter act as electrolytes by which gold is deposited in place of calcium, then the action is the result of milling in gold-bearing cyanide solution in place of alkaline water; and may be suggested as an explanation to account for the experience of J. W. Hutchinson,† borne out by myself and others, that treatment, after crushing in cyanide solution, necessitates a longer time for the recovery of the gold than required when the ore is crushed in water and given a preliminary alkaline treatment. It is also interesting to note that the problem of clarification of solutions after milling-in-cyanide is invariably obtrusive, whereas after milling-in-water trouble is seldom experienced in this direction. In other words, the electrolytic value of gold-bearing cyanide solution is inferior to that of lime water; and when once the slime particles are charged with the former no addition of lime will materially hasten coagulation.

A further, and perfectly reasonable assumption may be made, that the gold in the finest condition and associated with the ore may be in the colloidal state. Any clay may actually absorb gold either during or after the process of water absorption. Marshall and Welker‡ have shown that colloidal aluminum hydroxide in the form of a thin jelly is capable of completely absorbing gold from its colloidal solution. This aspect of gold absorption may not need more than passing mention, although it may have a greater bearing on gold recovery processes than we are inclined to admit at present.

In the selective absorptive qualities of clay it is more than likely that gold and silver compounds are absorbed into the structure of the colloid. Their complete recovery may be either impossible or impracticable. Theories regarding dissolved and undissolved gold and silver may have to be modified. Metals that cannot be rapidly washed from colloidal clay may not necessarily be undissolved; it is very likely that they were partly dissolved and later absorbed. Experiments have proved this. When colloidal clay in emulsified form is milled in lime-water, the colloid assumes a temporary equilibrium as far as absorption of water and salts of water is concerned and absorption and adsorption have occurred. Any further interchange of solution will then be a matter of slow dialysis. Hence, when this clay substance comes into contact with cyanide solution, it may be less likely to abstract the dissolved or undissolved metals associated with the ore during the limited time of agitation and treatment.

On the other hand, if a clayey ore is milled in an alkaline cyanide-solution carrying gold, or into which gold immediately dissolves, there is no reason to assume that the colloid will exhibit any selective action to the exclusion of the gold compounds. Absorption equilibrium will then be reached with a gold-bearing solution which can only be displaced with difficulty, or not at all.

Colloids may be divided into suspension colloids and emulsion colloids. The former may be coagulated by mechanical means; they possess marked electrical properties; they can be precipitated by very small quantities of electrolyte; and they possess little or no viscosity in solution. In emulsion colloids, on the other hand, the hydrosols show an absence of electrical phenomena; they form viscous solutions; and are not coagulated until the concentration of the electrolyte in the solution is comparatively high. The common action of emulsoid clay is probably one of absorption. Colloids may be liberated during ore reduction, but not produced; actual observation at the Miami mine, Arizona, proves this.

In wet processes of ore reduction, and when clay compounds are milled and treated in a cyanide solution containing gold, it would seem probable that an absorption

*Abstract of paper read before the Institution of Mining and Metallurgy, London, December 16, 1915.

†*E. & M. J.*, July, 1912.

‡Jour. Amer. Chem. Soc., 1913.

of such solution occurs in the honeycomb cells of the colloid, and that subsequent displacement of this metal must necessarily occupy a much longer time than did its absorption. The absorption is due to direct imbibition, but displacement under normal conditions is probably due to a slow-acting osmotic pressure when the colloid slime is surrounded with wash solution or water. It is also probable that any absorptive equilibrium is only temporary under such conditions, and that cell content varies with the composition of the surrounding medium.

The question arises as to the relative merits of a slow decantation as compared with a rapid filtration process for the removal of the dissolved metal. It would seem that a combination of the two, in the order stated, would be the most efficient.

It is generally recognized among metallurgists that a considerable time of contact is necessary in washing operations with certain classes of ores; and that theoretical displacement figures do not hold good in practice. From what has already been said, it is apparent that time of wash should not always be based on estimates of gold in solution which is apparently dissolved, as compared with gold associated with the ore which is apparently undissolved. In practical work it is generally found that, although the metal which has been dissolved may be apparently replaced fairly rapidly by ordinary means, a further abstraction of metal from ore occurs after prolonged contact with wash solution. This fact would furnish additional evidence that the gold solution so recovered is, in part at least, being drawn from the cells of the colloid slime, and not merely washed off the surfaces of the slime particles.

At some of the Kalgoorlie mines the value of prolonged washing in filtration treatment is not so obvious, and comparatively short washes are given that abstract a high proportion of recoverable gold from the ore. In this instance it may be assumed that previous roasting treatment has, in some cases, destroyed the colloidal envelope, thus reducing the possibility of absorption to a minimum.

It is obvious that the absorption by clay of bases in solution must affect density of sp. gr. estimations; and the water may contain water of combination that should not be destroyed. Such water is part of the ore. The hygroscopic moisture, on the other hand, must be completely displaced. It is almost impossible to calculate a true hygroscopic moisture percentage in unground rock, or to estimate the actual quantity of dry ore in a large sample with any degree of accuracy. The correction for such moisture in cases where the ore is automatically weighed, or calculated from mine-car content, are often at fault.

He emphasizes the ill-effects on the efficiency of classification and concentration processes when colloid clay forms a constituent of the pulp. To this I agreed in the same journal of July 19, 1913, on the benefits of desliming prior to classification; and also with the question of the accretion of viscous clay on the sides of classifiers, settlers, and similar apparatus. As a remedy in the case of settling-apparatus, I drew attention to the benefits arising from the general adoption of vertical-sided settlers in place of those of the spitzkasten type; and of vertical-sided classifiers in place of cones. Both these types of apparatus are arranged for the mechanical displacement of settled solids.

The viscous nature of settled colloidal clay is sufficiently obvious, and any comparative illustrations would be superfluous. On the other hand, the rapid decrease in the fluidity of a pulp, which results from the inclusion of clay in suspension, is considerable. A recent experience in connection with the settling of clay pulp may be of interest to others as it was of anxiety to me at the time. In this instance the amount of clay passing through the mill delivered intimately associated with the ore, and also in the form of pellets and balls of plastic and highly decomposed material, on more than one occasion caused an overload of the settling plant. The result was that the thickening efficiency of the settlers decreased as the amount of colloid material increased, and as soon as the fine slime commenced to overflow from the thickener, practically all the de-watering had stopped. The underflow then contained almost as much water content as the feed into the thickeners.

A further effect of the viscosity of the pulp was then noticeable. Classification became completely disorganized, and the fine sand escaping from the grinding plant was so buoyed up by the viscosity of the pulp that it traversed the radius of the settling tanks with apparent ease, and overflowed at the edges.

Examination of the clay pulp showed that the particles were in the gel form; that no addition or reduction in the amount of lime added had any appreciable effect in hastening settlement; and that the failure to settle was due to the preponderance and accumulation of this material which had absorbed large quantities of water and swelled accordingly. Although the clay entered the plant as unavoidable waste, it left on the residue carrying gold from which it could not be dissociated with ordinary washing methods.

In conclusion it may be said that:

1. The paper has been compiled to explain several points that have obtruded themselves from time to time in practical work. These include: (*a*) the fact that a complete extraction of gold from even the finest slime is impracticable; (*b*) the difficulty in the treatment of clay ores, as well as of ores with which clay is associated; (*c*) the fact that the cyanidation of accumulated clay slime often results in a lower extraction than would have been the case had it been treated direct from the battery; and (*d*) the fact that the milling of clayey ore in a gold-bearing cyanide solution invariably necessitates a longer time for treatment, and results in a higher residual metal content than would have been the case had it been milled in alkaline water.

2. The facts adduced indicate the highly absorptive properties of colloidal over non-colloidal clay, and show the powers which clays possess of retaining liquids and dissolved salts.

Drill Shanks and Bits

By P. B. McDonald

THE matter of drill-steel shanks is not clearly understood by many mine-superintendents, particularly as applying to steel for the increasingly popular mounted hammer-drill type of drills. Obviously it is not possible to use the same sort of chuck with a hammer-drill as is employed in a piston-drill, because the pounding by the hammer on a steel that is rigidly held would only waste the effort. The so-called 'standard Leyner drill-steel' is 1¼ or 1⅛-inch round steel; each drill-steel has two lugs on its shank, as shown in Fig 1. These lugs, when the steel is shoved into the drill-chuck and given a fractional turn, serve to hold the steel in the chuck, both to facilitate rotation and in order that, if the steel gets stuck in the hole, the cranking back of the machine will extricate the drill. But some superintendents do not like these lugs, which, they say, are difficult for the blacksmith to make. To avoid the use of lugs on drill-steel for a mounted hammer-drill, hexagon drill-steel can be employed to insure rotation, as with stoper or sinker drills; this, however, necessitates a chuck somewhat different from the regular Leyner type. If the steel gets jammed in the hole, it is pulled out with a wrench; a sinker-drill, like the 'Jackhamer,' has a special 'puller' attached to it, being an ostentatious feature of that machine.

Drill-steel without lugs is likely to get pushed too far into the machine, injuring the efficiency by shortening the stroke of the hammer. To obviate this a collar is made on the steel, as shown in Fig 2. This limits the distance that a steel can be pushed into the machine. However, one of the best methods is to use a tappet or anvil-block between the steel and the hammer of the machine: an additional advantage is that the anvil-block saves the hammer from becoming battered against the drill-steel.

E. M. Weston, in discussing South African drilling practice in the *Mining Magazine*, stated that "the whole theory of the design of rock-drill bits as formerly expounded is wrong. The point most insisted on has been the necessity for allowing ample clearance between the wings of the bit for the ejection of cuttings." That is why the four-point cross-bit has been the standard for so long. It is now being demonstrated that the four-point cross-bit is by no means so efficient as more blunt bits properly designed to drill a rounder and more even hole while holding their gauge to better advantage. Hollow steel, as now used with hammer-drills, effects satisfactory removal of the rock chippings or mud by forcing water or air against the bottom of the hole. As Mr. Weston points out, "the more we make the bit into the shape of a piston with small openings for the escape of water and cuttings, the more violent will be the ejection of cuttings, which are thus not pounded up at all, greatly increasing the drilling speed," and again, "it is quite feasible to use 1¼-in. steel with a hollow core of ½-in. diameter, or 1⅛-steel with ⅜-in. hollow core, such that the rock in the centre of the hole would be drilled around to form a core and broken off in large pieces, reducing the cutting necessary."

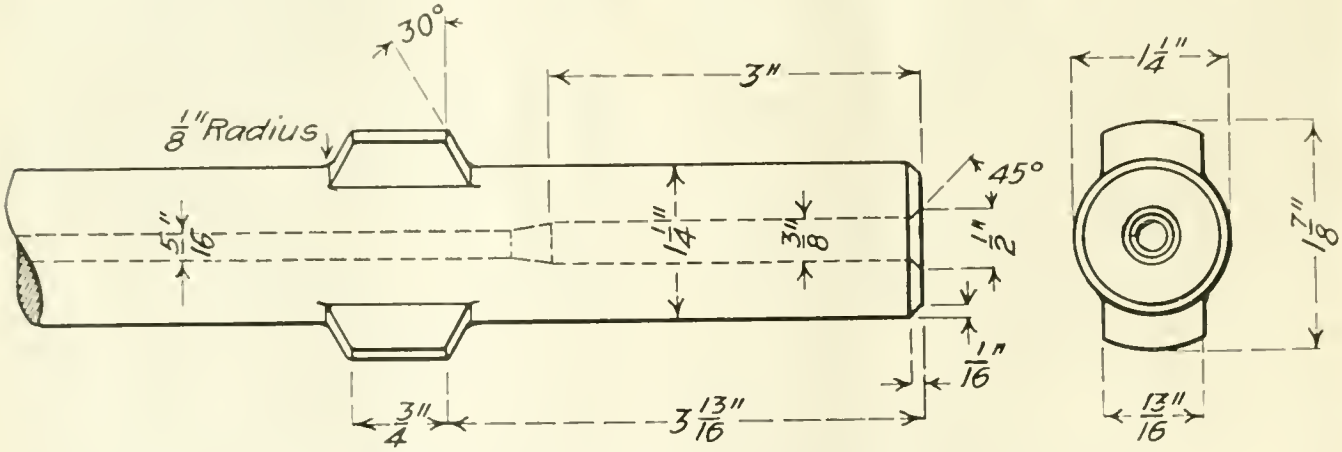

FIG. 1. A DRILL-SHANK ON ROUND STEEL FOR MOUNTED HAMMER-DRILLS. NOTE THE TWO LUGS.

It does not require much perspicacity to see that the ordinary four-point cross-bit with its comparatively fragile edges soon dulls and wears away. This is where the new blunt-looking bits, such as the H and Carr, show to advantage. They hold their gauge much better than a cross-bit while drilling as fast or faster. The special feature of the design of the H-bit is its two parallel cutting edges, as compared to the one edge of the Carr bit. In the course of trials at the Gastineau mine, near Juneau, Alaska, two mounted water-hammer drills

secured to a single cross-bar were tried with an H-bit of the International High Speed Steel Co. in competition with an ordinary cross-bit. The results showed a small advantage in the actual speed of drilling of the H-bit over the cross-bit, and a much greater advantage in not fitchering in bad ground. Furthermore the blunt and dull-looking H-bit did not require sharpening nearly so often, one set of steel out-drilling and out-lasting two sets of the cross-pointed steel. Variations of the chisel types of bits have their advocates, on account of the room allowed for the escape of mud. In reality the Carr bit is of the blunt-chisel variety, while the H-bit

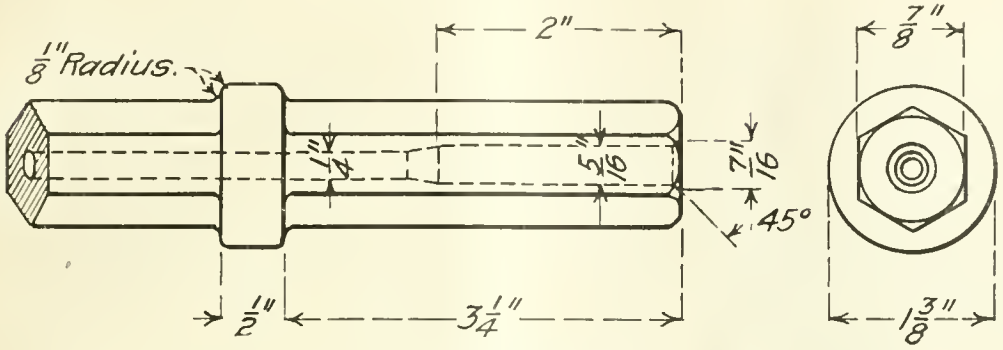

FIG. 2. COLLARED HEXAGONAL STEEL.

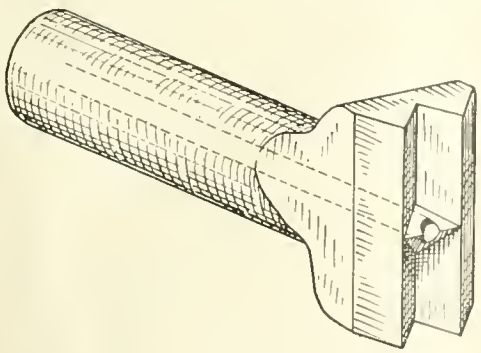
may be called a double-chisel type. However, while the simple chisel-bit may be effective in some rocks with hammer-drills, it has definite limitations particularly with piston-drills. That the introduction of improved drill-bits is a matter of no small consequence is indicated by a statement by James MacNaughton, general manager for the Calumet & Hecla Co.; he said, "the use of the one-man drill and Carr bit resulted in an increased output per miner equivalent to his total production of a few years ago."

Regarding the so-called flat cross-bit—or low-centre cross-bit, which soon wears to the same shape—that is,



THE H-BIT.

with edges slightly flattened in proportion to the distance from the centre (illustrated in the MINING AND SCIENTIFIC PRESS of Nov. 6), it is clear that the additional metal in the wings makes reinforced edges that stand up to the work in hand, giving a stronger and more resistant bit than the ordinary cross-bit, because holding its gauge much longer. The whole idea is to get a bit that will not wear on the edges as quickly as the cross-bit; any method of reinforcing the peripheral edges, while not impairing the cutting speed or impeding the ejection of cuttings, is salutary, and represents the goal as at present recognized.

Geological Survey Cannot Make Assays

The U. S. Geological Survey calls the attention of mining men and others to the fact that it is not equipped for making assays or analyses of rocks, its laboratory being in fact overloaded with official work. Many specimens and samples are received by the Survey, accompanied by requests for such treatment, with which it is impossible to comply. The force of chemists employed is small, and their time is fully occupied by their regular official duties. The Geological Survey has no facilities for making gold and silver assays. The most the Survey geologists can do is to give an off-hand opinion based on a simple examination of the specimens. It might be a matter of surprise to know the large number of answers prepared daily by the Geological Survey, similar to the following:

"In reply to your letter, etc., * * * the material you send is merely a fragment of a quartz pebble. I regret to say that it has no probable value."

A great many other samples received prove to be iron pyrites, or "fool's gold," the shiny particles being taken by the writers for gold.

If an assay is desired, the proper course is to employ a private assayer or to send the specimen to one of the Government assay offices, where a regular charge is made for such work. When specimens are sent to the Survey for examination, applicants should be particular to state whether they wish them returned, as otherwise they will be destroyed. There are Government assay offices at Carson, Nevada; Seattle, Washington; Boise, Idaho; Helena, Montana; Salt Lake City, Utah; Deadwood, South Dakota; or New Orleans, Louisiana; and the Mint at Philadelphia for gold, silver, lead, tin, zinc, and antimony.

DRILL-HOLES 7 ft. deep in a tunnel of the Catskill aqueduct near New York were started 2 in. diameter and bottomed 1⅝ in. diameter, changes of steel being made every 2 ft., says Charles A. Hirschberg in a recent article on drilling practice. That is, the reduction on successive changes of steel was only ⅛ in. This is an example of the increasing tendency to reduce drilling by decreasing the differential in diameters of successive bits. In the tunnel job mentioned, four mounted hammer-drills on two columns were employed.

On the Science of a Froth

By Will H. Coghill*

THE paragraph on the character of froth in Mr. Callow's article in the MINING AND SCIENTIFIC PRESS of December 4, 1915, page 852, led me to refer to some notes that have been pigeon-holed for some months. I think that a little mathematics can be applied to good advantage.

Before taking up the mathematics, however, I wish to mention some principles that I think have not been sufficiently emphasized in the articles on flotation; that is, a distinction between the properties of aqueous and non-aqueous films.

The little book on 'Surface Tension and Surface Energy,' by Willows & Hatschek, shows how the elastic film analogy in the study of froth will get one into no end of trouble if not handled with care. It is the characteristic of analogies to break down when pressed too far, though they are useful up to a certain point. This one is no exception. In the case of india-rubber it is obvious that a given weight can only stretch this to a definite extent. To further enlarge the rubber film, an additional weight would be required; while with a liquid film this is not true. Reference to a recent article[1] shows that the measure of surface tension is not when the film breaks, but at the instant when the wire is pulled away from *AB*. If the wire is pulled a great distance without breaking the film, the total energy of the surface is increased, of course, but the energy per unit-area and surface tension are unaffected. Whether or not the film breaks, depends not upon the surface tension, but whether or not there is enough liquid to supply the added area. The difference between a non-aqueous substance and a liquid film is, that in stretching the former the molecules are distorted or separated while in stretching a liquid film molecules come from within the liquid to occupy the new area. According to Devaux,[2] the surface tension phenomenon disappears as soon as there is no more liquid to come from within. The same laws apply to surfaces that are allowed to contract. The rubber has a constantly decreasing force of contraction as it approaches its original dimensions, while a liquid film always tends to contract with the same force independently of its size. Now, it is a common practice in demonstrating physical principles to omit certain qualifying conditions until the main features are outlined. This method must be pursued here. The qualifying statement is, that, in the case of a contaminated liquid, the film may not "contract with a force independently of its size"; that is, after learning to look upon surface tension as a constant force we must now view it as a variable force. Take, for example, the explanation of the effect of oil on waves.[3] When a small wave is formed on the surface of water the surface is stretched; for, obviously, the wavy surface has greater area than the plane surface. Owing to the stretching of the surface the oil film is made thinner so that the contamination due to oil is reduced, and hence the surface tension is increased; this increase in surface tension tending to oppose the production of the wave.

Again, Edser[4] discusses variable surface tension under the heading 'Stability of a Liquid Film.' He shows that when a film is on a vertical rectangle[5] equilibrium is impossible unless the surface tension is greater at the top than at the bottom of the film. This is obviously due to the weight of the film itself. For pure water, the surface tension is nearly constant, and therefore, a water film more than two or three millimetres in height cannot be formed. A slight trace of grease will give the water a variable surface tension; if the surface tension at any point on the film is insufficient to produce equilibrium, the film stretches at this point, and the concentration of grease is diminished, so that the surface tension increases automatically and equilibrium is maintained.

He concludes by saying that the great stability of a soap film is due to the wide variation in surface tension between freshly formed and long exposed parts of the surface and that any stretching of the film, due to insufficient strength, immediately increases the surface tension. Now it seems to me that it is time for us to get away from the idea that low surface tension *per se*, is necessary for the formation of a froth, for Edser has made it clear that the contamination of the film with something that will give a variable surface tension is the essential. To be sure, this amounts to reducing surface tension, because contamination of water, with some exceptions, has this effect. The attorney who discoursed at great length upon surface tension and said that the longevity of a bubble was increased by decreasing the contractile drawing force of surface tension, was merely riding too far the willing horse that many of us have ridden so freely.

It is quite easy to accept the statement that soap contaminates water enough to afford a variable surface tension, but it is not quite so clear how a very small fraction of 1% of oil will give the same results, until we have considered adsorption.

Adsorption has been described several times in the

[5]The cut of the rectangle was shown in the article previously referred to in the *Mining and Scientific Press*, September 11, 1915.

technical journals, but I believe I am justified in taking it up again and quoting 'Surface Tension and Surface Energy,' because here we find the generalized statement describing adsorption in a liquid and its effect on surface tension. It says: "If the dissolved substance diminishes the surface tension of the solution, an excess of concentration in the surface layer diminishes surface energy. If, on the other hand, the solute increases the surface tension, the surface energy will be reduced if the concentration in the surface layer is lower than that of the bulk of the solution. This difference in concentration between the surface layer and the bulk of the solution is called adsorption and is a physical fact. The factors tending to produce adsorption are opposed to the factors tending to establish uniform concentration. The final distribution of a solute is the resultant of adsorption and two other effects, namely, osmotic pressure and electric charge. Important qualitative conclusions are drawn from theoretical considerations already developed. A small quantity of dissolved substance may reduce the surface tension very considerably, but it can only increase it slightly. Thus, sodium chloride increases surface tension of water to a small extent; the concentration in the surface layer is accordingly smaller than in the bulk, and the effect of the solute is thus partly counteracted. On the other hand, many organic salts reduce surface tension, and therefore accumulate in the surface layer; so that in extreme cases, the whole of the solute may be collected there and produce a considerable effect, although the absolute quantity may be exceedingly slight."

Adsorption is of such unmistakable importance that we will refer to 'The Chemistry of Colloids,' by W. W. Taylor, for a different perspective of the same thing. Here I quote freely, for I am not intending to advance my own theories, but to bring out what seem to me to be pertinent physical facts. And here I wish to state that I fear that the premise for my recent calculation[6] of the carrying capacity of the surface of a liquid is not correct. It was an attempt to elaborate on a weak statement in a text-book, and hence the calculations themselves cannot be credited.

Adsorption, in its most general sense, implies the unequal distribution of substances at the boundary between two heterogeneous phases: solid-gas, solid-liquid, and liquid-gas. We are concerned just now with only the last.

The surface layer of a liquid is under great compression, due to the big difference of the molecular forces on the two sides of the interface, and consequently the concentration in the surface of a solution must be different from that in the bulk of the liquid. For just as unequal temperatures in a dilute solution cause an unequal distribution of the solute, so from the same law unequal pressures must also produce an unequal distribution. This pressure (due to surface tension) always, in time, adjusts itself to the minimum, for a component which lowers surface tension is always increased in the surface layer whether the component be present as solvent or solute.

We now have a new principle to apply to a bubble, to wit: on account of adsorption a fresh surface always has a greater surface tension than an old one; thus if it is stretched locally by conditions tending to break it, it is automatically reinforced at that point.

It is now obvious that without adsorption it would be impossible to realize a variable surface tension, for if the solution were contaminated uniformly throughout, a fresh surface exposed by the stretching of the film would have the same energy as the old surface, and the ultimate result would be identical with the case sited where pure water was used.

In this argument I have assumed that the contaminating substance is soluble in water. I realize fully that many of the flotation oils are said to be insoluble in water, but I maintain that solubility is only relative, and further, we known nothing about the multiplicity of chemical reactions possible in a pulp which might release contaminating substances that would produce the adsorption phenomenon. If graphite, for instance, acts as a frothing agent, it might have to be treated as a special case and could not be taken as proof that the above arguments are invalid. If the flotation oil is extremely insoluble in, and lighter than, water there would be an oil film at the liquid-air interface and over the liquid film containing adsorbed oil. It might be well at this point to drop the subject of variable surface tension and undertake to get a better idea of the absolute value of these forces. One physicist has spoken of them as being enormous.

As far as surface tension is concerned it is theoretically possible to blow a soap bubble as big as a house.

Take the formula:

(1) $P = \frac{4T}{r}$

Where T = pull due to surface tension in grams of a film of one surface and 1 cm. long.

P = excess pressure inside per unit-area, and r = the radius of the sphere.

This formula takes into account the pull on both the internal and external surfaces. It needs no demonstration, as it is derived in the same manner as the old familiar formula used in calculating the thickness of boiler-shells, etc.

In case of a liquid drop or a bubble submerged in water, the formula is:

(2) $P = \frac{2T}{r}$

Now let us use these formulæ to make a little study of the mathematics of a bubble to see how much variation of surface tension and external pressure amount to when numerically expressed and see if Mr. Callow's argument is good.

He states: "The bubbles * * * being generated under hydraulic pressure varying from 15 to 40 inches, on rising above the water * * * burst by reason of the lower surrounding atmospheric pressure." This pictures the emerging bubble as expanding like a bladder when suddenly inflated by increased internal, or de-

[6]"Surface Tension," *Mining and Scientific Press*, October 9, 1915.

creased external pressure and is a misconception. To make the steps more simple we will first study the bubble in the air and then when submerged.

Assume 1 cc. of free air taken in form of a sphere.

(3) $V = 4.2r^3 = 1$

$r = 0.620$ cm.

Now suppose this air to be enclosed in a liquid film in air where the liquid air surface tension is 70. The new radius can be calculated by the application of Boyle's law, which is, that the pressure varies inversely as the volume, where absolute pressure is of course understood. The free air is, in round numbers, under a pressure of 1000 gm. per sq. cm. and a surface tension of 70 dynes per cm. exerts a pull equivalent to a weight of approximately 0.07 gm. per cm. of length.

The proportion used to calculate the new radius is:

$1000 : (1000 + \frac{0.2}{r}) :: 4.2r^3 : 1$

(4) $4200r^3 + 1.176r^2 = 1000$

$r = 0.619$

$P = \frac{2T}{r} = \frac{1.2}{0.619} = 0.453$ gm. per sq. cm.

The second term of equation (4) is the only one that contains a function of surface tension, and since it is of such small numerical value, it is plain that any variation of surface tension has very little to do with the radius of an individual bubble in air. Even when the surface tension varies between zero and a maximum, as in (3) and (4), the change of radius is, in fact, too slight to be calculated on the slide-rule—only from 0.620 to 0.619 cm. It is interesting to note that P has a value of 0.453 gm. per sq. cm., which equals 0.006 lb. per sq. in. This is the order of magnitude of the forces that cause a spray above the froth.

Suppose again that the bubble is 1 cm. below surface. We then have:

(5) $1000 : (1001 + \frac{0.14}{r}) = 4.2r^3 : 1$

$r = 0.618$

$P = \frac{0.14}{0.618} = 0.226$

Total pressure $1 + 0.226 = 1.226$ (gauge).

Finally take a depth of 75 cm.

(6) $1000 : (1075 + \frac{0.14}{r}) :: 4.2r^3 : 1$

$r = 0.561$

$P = \frac{2T}{r} = \frac{0.14}{0.561} = 0.250$

Total pressure $= 75 + 0.250 = 75.250$ (gauge).

These results are shown in the appended table:

ONE CUBIC CENTIMETRE FREE AIR

No.	Description.	r	P	Gauge pressure.	Absolute pressure.
3.	Free air	0.620	0.000	0.000	1000.000
4.	Liquid film in air	0.619	0.453	0.453	1000.453
5.	Submerged 1 cm.	0.618	0.226	1.226	1001.226
6.	Submerged 75 cm.	0.561	0.250	75.250	1075.250

Column r shows that a bubble emerges with an infinitely small change of radius. In fact the change is on the side of decrease because of the surface film being doubled. Now, since there is practically no expansion or contraction upon emerging from the liquid, it seems to me that "low surrounding atmospheric pressure" has nothing to do with bursting Mr. Callow's bubbles. Of course it is well known that if a gas bag is burst under water the gas remains under confinement; whereas if it is burst in air it is evanescent, but it is necessary for the metallurgist to study the texture of these bags.

Since a bubble does not expand, how are we going to account for "4-inch bubbles"? By coalescence (unless electrification plays a part). Sometimes they cohere but do not coalesce. When they coalesce the large one robs the small one because pressure varies inversely as the radius (see Equation 1). The little one 'pumps' its gas into the large one. We shall have to learn how to control coalescence.

Viscosity is another important factor that must be considered along with variable surface tension and coalescence. It is not surface tension that breaks bubbles, but it is blows upon a surface that lacks viscosity or toughness and variable surface tension, that cause rupture. They rupture easily on account of lack of friction of the molecules. With low friction a blow is likely to cause the molecules to be separated a distance at which surface tension phenomena disappear before other molecules have time to come from below and reinforce the area with their greater surface tension.

The books all emphasize the importance of great superficial viscosity and small internal viscosity for the persistence of a froth. It is said that alcohol which has a superficial viscosity less than the internal viscosity, when mixed with superficially viscous liquids, will neutralize the relative surface viscosity and make frothing impossible. Hence the practice of adding a few drops of alcohol to check frothing in pharmaceutical work. We know that tannin sometimes interferes with flotation work and also that it may form a colloidal solution with water. May we not add that alcohol and tannin are deterrents because adsorption is checked on account of internal viscosity produced by them? For, without adsorption, one of the leading factors tending to produce a stable froth is nullified, that is, variable surface tension.

My best thanks are due to Dr. W. B. Anderson, professor of physics in the College, for his helpful suggestions and critical reading of these notes.

THE STRAITS OF MAGELLAN are known to contain gold in placers, and 15 dredges were built in Tierra del Fuego several years ago to recover gold from that remote district. However, only one dredge worked intermittently during the past three years. T. C. Earle, writing in the London *Mining Journal*, states that the production of gold in the Magellanes declined from 6300 oz. in 1904 to 1000 oz. in 1912. "It is," says this writer, "a land of perpetual tempest, dreary, bleak, treeless. The apathetic attitude of the Chilean government is not conducive to industry there. The settlement of Porvenir, ten years ago a flourishing mining town, is today a collection of empty shanties with boarded-up windows."

A PIECE of drill-steel, 2½ ft. long, preferably solid, may be handy on a supply-clerk's or foreman's desk for obstreperous or threatening visitors.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

One ton of tungsten metal will make filaments for 18,000,000 electric incandescent globes.

In cutting rubber for gaskets the work will go much easier if the blade of the knife is kept wet.

Gypsum is soluble in 500 parts of water, and completely soluble in boiling hydrochloric acid.

Scheelite is soluble in nitric or hydrochloric acid, leaving a yellow residue that is soluble in ammonia.

Cinnabar is amenable to flotation. In fact, its ready tendency to float was the cause of failure in treatment by water concentration.

The belt-conveyor is an efficient method of transportation, requires little power, is relatively moderate in cost, and needs few repairs.

The first piece of gold found in California by James W. Marshall was worth 50 cents, and the second, $5. They were paid out for provisions and all trace of them was lost.

Drill-bits are improved, several authorities say, by being hammered while sharpened. The advocates of hammering claim that the steel is thereby toughened and strengthened.

Abandonment of a mill-site results as follows: if the required work is not performed upon a lode-location it becomes forfeitable, following which the attached mill-site is also forfeitable.

Bonuses to miners are frequently paid by a check separate from the regular pay-check, in order to visualize more conspicuously, to the men, that they are receiving extra pay for extra effort.

A tram-car will hold more broken rock and take longer to load when the rock is fine than when the pieces are large and fewer. For that reason miners who tram their own rock on contract are likely to blast so that the rock is not broken too fine.

Fatigue of drill-steel is worth providing against by having on hand an amount considerably in excess of requirements so that each steel will receive a longer rest between drilling periods. The same phenomenon is common with razors or safety-razor blades for shaving.

The Braden was the first of the large low-grade copper companies to introduce oil flotation on a complete scale, being a pioneer in this direction. According to a recent report by Pope Yeatman, in any new process difficulties are encountered, the chief in this one being due to the variability of the oils, especially of the wood-tar varieties. Thus it may be mentioned that by reason of the low extractions in April and May last, caused by proper oils not being available, recovery decreased to a little over 69%, and immediately on receipt of the correct oil, in the latter part of May, it jumped to over 75%.

Enrichment of the upper or superficial parts of a gold-quartz vein is often the result of simple concentration. The leaching and removal of the pyrite is effected without the shifting of the gold, which remains behind in a honeycombed mass of iron-stained quartz. Thus this part of the vein loses weight without reduction of volume, so that the ore is so much the richer per ton.

In some cases the leaching of the upper portion of a gold vein may produce solutions in which the gold is soluble sufficiently to cause it to migrate downward and to be precipitated near the water-level, which not infrequently coincides with the base of the zone of oxidation.

Oxidation of the pyrite in the outcrop of a gold vein renders it soluble in surface-water, while the gold, which is relatively insoluble, survives to make 'specimen' ore. In the cubes formerly occupied by the pyrite will be found crumbly native sulphur and fine crystals of gold that are easily shaken loose.

This applies also to gold when associated with copper pyrite and other copper minerals. The superficial leaching may so concentrate traces of gold in the vein as to make the outcrop valuable for that metal, while the leaching of the copper leaves a gossan, or sintery mass of ironstone, enriched as to gold but impoverished as to copper. This is exemplified by the early mining at Butte.

Mine timber deteriorates from several causes, but perhaps the most unique was an instance on the 1300-ft. level of the Knights Deep mine on the Rand, where white ants had bored into the caps of some sets. If these insects should spread through the mines they might become a menace to the timbering.

Rock-drilling by contract, with payment made per foot of hole drilled, has not usually worked out satisfactorily. The miners place the holes where they are drilled most easily rather than where the smallest number of holes will break the greatest amount of ground. A price of 6 or 8 cents per foot of hole drilled was paid in hard limestone in Missouri.

Rutile and ilmenite are both used in the manufacture of ferro-titanium, which is employed in making steel and cast iron. Both are used in making electrodes for arc lamps. Rutile is the source of titanium for making cupro-titanium for use in brass and other copper-bearing alloys, and for making potassium titanium oxalate, used in dyeing leather and textiles. A little rutile is also used in ceramics.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

NOTES ON THE RECENT FATAL FIRE. ELECTRIC LOCOS.

As mentioned in a telegraphic dispatch to the PRESS, published on page 289 of the February 19 issue, fire broke out on the 1200-ft. level of the Anaconda company's Pennsylvania mine on February 14. Nineteen miners and two members of the rescue parties were asphyxiated. The Pennsylvania has two openings, the main hoisting shaft, down 2800 ft., and an air-shaft, 1800 ft. deep. The fire apparently started on the 1200-ft. station of the air-shaft. The station-tender was the first to notice the fire, the place then being a mass of flames. Quick work on the part of the station-tenders and foremen was responsible for saving the lives of the 200 men who were hoisted to safety. An old fire has been smoldering for many years in some of the adjoining mines that are connected underground with the Pennsylvania. When the alarm spread, the impression was given that one of these old fires had broken out. This misapprehension no doubt was the cause of most of the deaths, as the men in that part of the mine where the smoke was thickest naturally ran toward the air-shaft, and in doing so they ran right into the source of the gas and smoke. The assistant foreman and a member of the first-aid crew put on Draeger helmets and made several trips into the smoky depths. A carbide lamp would not burn in the smoke and electric flash-lights were used. Later an electric extension cord 50 ft. long was fitted with 20 globes, and it was impossible to see from one globe to the next. The last trip these two men made was to the 600-ft. level. They were in some distance from the station when the first-aid man dropped. Some hours later when the next rescue-party was able to get off on the 600-ft. level they found the assistant foreman and the first-aid man lying on the track near the station. Heroic efforts were made to revive these men when they were brought to the surface, but the gas has the effect of hardening the lungs, and artificial respiration was tried for four hours without effect. It is thought that in the dense smoke the first-aid man unconsciously pulled at his goggles, as one will when his vision is poor, and thus loosened his mask, which would allow the helmet to fill with gas. The assistant foreman was known to have a weak heart, and he had been warned not to wear a helmet. He probably died of heart failure. Several miners and some members of the rescue-parties who were found shortly after being overcome, were brought to the surface and revived without much trouble. A big exhaust fan was quickly installed at the head of the air-shaft, in an effort to clear the workings of smoke and gas. The timbers in the air-shaft were on fire between the 1200 and the 1000-ft. levels, and water was poured down the shaft in an effort to extinguish the blaze. The fire weakened the timbers and the shaft started to cave. Blocks of ground and timbers could be heard falling through the shaft. As soon as all the bodies had been brought to the surface, and it was certain that no one was trying to escape through openings to adjoining mines, these connections were sealed with concrete bulkheads. The gas had already spread to some of the other mines, so that the regular shifts could not work. Several of the men engaged in building bulkheads were overcome, but they were all revived. The origin of the fire is not known. There is a large electrically-driven fan at the 1200-ft. air-shaft station, and more or less oily waste and grease might have accumulated here, and the careless use of a lighted candle or a short circuit would have started a blaze. An effort is being made to confine the fire to as small an area as possible with bulkheads, but it is still burning fiercely and the thick smoke makes all operations difficult. The miners had left their dinner buckets and hats behind in their scramble for safety. Some of the bodies bore marks that indicated that they had been kicked by the half-crazed horses running through the drifts. The Pennsylvania is one of the old mines of the Anaconda company, and one of the few that has not been entirely equipped with electric haulage. Eight horses perished. The removal of their bloated carcasses was a difficult job. The fire has spread to the drifts and stopes, and the ore is burning. The U. S. Bureau of Mines telegraphed that it would send its rescue-cars if they would be of assistance, but the rescue equipment and organization of the company are so complete that help was not needed. Ore will not be extracted from the Pennsylvania for some time, but this will not curtail production, as the other mines can supply all the ore needed for the smelters.

The electrified division of the Chicago, Milwaukee & St. Paul railroad from Three Forks over the continental divide to Deer Lodge, a distance of 115 miles, gave excellent results during the recent cold weather that prevailed all over Montana. The great electric locomotives had no difficulty in dragging their loads over the mountain through the snow. Twenty-one miles of this distance has a grade of 2%. Four hundred and forty miles will eventually be electrified at a cost of $12,000,000. The electric energy is generated by water-power. The new locomotives will operate over two of the old steam divisions, and thus eliminate round-houses and yards at intermediate points.

It is rumored that the Anaconda company will take over the Pilot Butte holdings on a basis of $14 per share, or $1,400,000 for the property. The situation at the Pilot Butte is similar in some respects to that which prevailed at the Butte-Alex Scott, previous to the sale of the latter to the Anaconda company. There has been considerable litigation, and as a result ground belonging to both has been tied up, with resulting high expense. The easiest way out of it is by an absolute sale of the Pilot-Butte to the Anaconda, as the latter with its greater facilities can operate the property to better advantage.

ATOLIA, CALIFORNIA

SMALL TUNGSTEN PRODUCERS AND LARGE COMPANY CLASH.

The pent-up friction which has developed for nearly a year between the Atolia Mining Co. and the outsiders who have opened adjoining claims in the Atolia tungsten district, broke out on February 13. A temporary truce was agreed upon by the opposing factions.

Last year James M. Rice staked a claim adjoining the Atolia company's holdings on the south side, at a point where another claim, not owned by the same company and known as the Toboggan, also meets the company's southerly side-line. The Toboggan is being worked by its owner, Geo. B. Landers, of Bakersfield, who has several lessees working, extracting rich ore. Rice also has been working continuously since last summer, and his rich finds have attracted much attention ever since.

The rich float marketed by the lessees and workers of these and other newly-developed claims in this district has found

its way into Eastern markets in competition with the Atolia's product. The small miners are selling in small quantities, for cash, to agents on the ground, at such prices as the exigencies demand, in order to get funds to open their properties.

It is not, therefore, a very intricate problem to note the causes leading to probable friction between the representatives of the company which controls a hundred or so claims in one 'blanket' location, and the many small individual miners who have lately been responsible for the development of what means a promising centre in the tungsten industry.

On February 13 a surveyor is said to have re-located the original lines of the Atolia company's boundaries, and what portends an open row and, possibly, a big law-suit, become apparent. The 'potato patch' has proved a wonderful producer of high-grade scheelite, discovered as alluvial on top of bedrock. Pieces weighing over a 100 lb. have been found, and the company has over three score men digging for this float at $3 per day, while the product is worth $2 to $6 per lb. in the East.

The contention of the American miners—the company hires mostly Italian miners—is that many of the company's claims have been located not as placer but lode claims, describing a certain lead, lode, or vein, and in many instances, it being 15 to nearly a 100 ft. to bedrock, there was no evidence of a lode on the surface, it being requisite that a showing of mineral in place is necessary to constitute a valid location of quartz claims. It is also contended, that in the area of 2000 acres, taken up and claimed by the Atolia company, many claims have been patented as lode or quartz claims on which no lodes or veins are manifest. The influx of new miners to the district, who are thoroughly prospecting it, is apparently responsible for increased development and an exposé of these conditions.

In the truce arranged, there is talk of the Atolia company entering as a purchaser of the claims conflicting with its rights. In the great area claimed by the company are many individual claims lying like so many islands entirely surrounded by it, which will ultimately bring about similar conditions manifested by the complications of yesterday.

In the January *Mining and Oil Bulletin* of the Chamber of Mines and Oil of Los Angeles, J. W. Glasgow briefly describes tungsten mining at Atolia. The mineral was discovered there in 1910 by A. D. Ray. The town is a place of tents, as shown by the accompanying photograph.

On account of the burning of the Atolia mill, tungsten ore has risen throughout the United States to over $60 per unit.

ATOLIA, CALIFORNIA.

TORONTO, ONTARIO

DOME, PORCUPINE CROWN, BEAVER CONSOLIDATED.—NICKEL REFINERY.

The new ball-mill at the Dome mill, Porcupine, is in full swing, crushing 1200 tons per day. Another similar machine is to be installed. The January output was $176,590. Recent developments include a cross-cut through 27 ft. of ore averaging $9.60 per ton, in addition to 58 ft. of $4.30 ore.

The annual report of the Porcupine Crown for 1915 shows a production of $615,537, with net profits of $299,116. The surplus on hand was $269,977.

The Triumph Mining Co., which has taken over the Success, has encountered a shear-zone in a cross-cut at the 100-ft. level.

At the Kirkland Lake, now worked by the Beaver Consolidated, the vein with 4 to 6 in. of high-grade ore, that came into the shaft at a depth of 110 ft., persists as sinking progresses. The shaft will be sunk to 200 ft.; it is being put down for prospecting purposes, and a main shaft will be sunk at a point where it is expected that the Teck Hughes vein system will be cut.

An important development has been made at the Patterson shaft of the Adanac on the claim adjoining the Ophir, in a winze put down from the 200-ft. level. The vein, which at first was low in silver, became much richer at a depth of 265 ft., showing native silver.

At the Foster a number of stringers have been picked up in the cross-cut which is being driven to cut the Lawson-Bailey vein system.

The Seneca Superior has declared a 10% dividend and a 10% bonus, making a total of 225% on the capital.

The Dominion Reduction Co. has taken a six months' option on the Big Master, Laurentian, and H. B. 298 properties in the Manitou Lake gold area in the Lake of the Woods region. The properties, which have been closed down for many years, are now being unwatered and sampled.

In pursuance of the policy of establishing the nickel refining industry in Canada the Dominion government has made an arrangement with the International Nickel Co., which now refines most of the output of the Sudbury mines in New Jersey, under which they will construct and operate a refinery at some point on the Canadian seaboard, probably Cape Breton. Some details yet remain to be settled. The plant will be operated under Government supervision, and the British government will have the first call on the output.

The Consolidated Mining & Smelting Co. of Canada has increased its capital stock from $7,500,000 to $15,000,000.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Bethel

(Special Correspondence.)—The Canyon Creek placers yielded a good deal of gold last summer from small scale operations. In the summer freight costs from 20 to 25c. per lb., in the winter, 5c. Bear creek contributed a quantity of gold to the output from this region on the few claims that were operated. The best claims are under bond. Miners on Aralik river near Gwinhagamut, got satisfactory results. Julian and other creeks near the George river, about 200 miles from here up the Kuskokwim, are producers of coarse gold. Nuggets worth as much as $15 and over are found. New York creek is also a producer. Candle creek near Tacotna keeps up its last summer's reputation of yielding a considerable quantity of gold. Mone creek contributes its share. One or two parties have been working on the Aniak river, but results are not known yet. Good reports are received from prospectors on other tributaries of Kuskokwim, especially from Hohohitna. More interest is taken in quartz prospecting, as some large veins containing gold, copper, and antimony have been discovered. It is reported that George J. Shoup of San Francisco is interested in eight antimony claims at the head of the Togiak river. Somewhere in the vicinity of Kwisluk river, Mr. Keeler, an old-time miner and prospector from Idaho, informed me that he has discovered a large lode of high-grade copper, lying between slate and limestone.

There seems to be no doubt that there will be great activity in auriferous lode mining on Kuskokwim in the near future, as soon as transportation facilities improve. With the bay and river charted up to the Bethel, the most difficult problems are overcome. On the gasoline schooner *Bender Brothers*, which arrived from Seattle yesterday, is apparatus for a Government wireless-station which will be established at Tacotna, with sufficient power to make connection with Seward. A wireless-station at this place certainly would be a godsend for the population on the lower Kuskowim, as we have had no mail service since the *Bender Brothers* left last spring. Letters dated June 3, 1915, at San Francisco, arrived October 8; but we hope that this matter will improve when the country develops.

Bethel, October 9, 1915.

(Special Correspondence.)—Windy creek, which was discovered in the latter part of last winter, and which is about five miles south from Canyon creek, is also a tributary of the Kwisluk river. Three claims have been prospected this summer with encouraging results. Some gold was extracted from one of the claims; it is coarse, and similar to that of Canyon creek. This adds one more creek to the producing list in this district, and as there is some prospecting going on this winter, there may be some more discoveries made before spring. A new strike is reported on the Aralik river near Gwinhagamut, which is supposed to be better than any previously made in this district. Aralik River placer mines produced $40,000 or over, so there is a good chance for some rich ground.

The boat *Bender Brothers* froze-in here this fall, and the *Abler*, according to reports, was wrecked, so there is the same old story of shortage of provision. At present writing there is no bacon, lard, butter, or potatoes in town, so it does not look very bright for the miners, who depend on the supply to be brought up in the winter to the different camps. As mining is steadily progressing, and the gold output increases considerably, it seems that there should be some one who would take the opportunity to send in a supply of provisions, which would be sufficient at least until navigation opens in the spring, and double their investment in six months time.

The town of Bethel improves with the development of the country, several new buildings having been erected this fall. Among the most noted is the Government public school building, which was built by the Bureau of Education. W. McMillan from the Kinak school is teacher.

Bethel, November 26, 1915.

Juneau

Information received at Juneau from Leonard Lehlbach at New York states that the Alaska Taku mine, five miles down Gastineau channel, is practically bonded to Eastern people for nearly $500,000.

On February 5 connection was made between 1600 and 1700 ft. in the new Ready Bullion shaft on Douglas island, making the total depth 2450 ft. at 70°. The four-compartment shaft will be finished within two months. A 100-ft. steel head-frame and electric hoist are to be erected.

There is a surplus of labor at Treadwell, a notice being posted to this effect.

ARIZONA

Cochise County

(Special Correspondence.)—Up to a year ago little attention had been given to that portion of the Warren mining district north-west of Bisbee, on the Escabrosa ridge at the head of Moore canyon. It was said to be out of the zone, and other than a few assessment holes sunk mostly by miners of the Warren district, little has been accomplished toward prospecting and developing the area.

The Mule Mountain Mining Co. started to sink in an abandoned shaft on its lease last September, but as gas was encountered operations were slow and uncertain. The company stopped work in the shaft until machinery could be installed. This shaft is now 50 ft. deep with a 10-in. vein of $20 lead-silver-gold ore in the face. Several stringers of ore have been uncovered, assaying as high as 53% lead, 79 oz. silver, and $2 gold per ton. In a drift, lead, silver, and gold, have assayed as high as that in the shaft, but in less quantity. A stringer of sulphide was found in the drift, and a winze sunk on it eight feet. The sulphide contained 0.5 to 1.5% copper, and widened from 1 to 4 in. in 8 ft. The company has installed machinery, and at present is driving a lower adit which will give a depth of about 350 ft. on the shaft workings.

The Blair and Grant property in Moore canyon is being prospected, and shows splendid indications.

The Pinole Exploration Co. holds a group of claims in this vicinity and will begin to develop them within 60 days.

Bisbee, February 8.

Gila County

Work has been stopped at the Inspiration 600-ton test-mill, which has been operating since early in 1914. The plant is to be dismantled.

The Superior & Boston is to unwater its levels below 800 ft. depth.

The Iron Cap company's shaft is to be enlarged from the

surface to 600 ft., and then deepened to 1200 ft. The output of copper ore in January was 28 carloads.

Mohave County

The Union Basin Mining Co. at Golconda has completed the installation of a 100-ton addition to its mill. This will bring the capacity up to 200 tons daily. Rolls, concentrators, tube-mills, and oil flotation are being used. The shaft is nearing 1000-ft. depth; sinking will continue to 1200 feet.

At Chloride a 20-room hotel is being constructed.

The Tennessee company is still sinking its main vertical shaft, four six-hour shifts being employed. Sinking will continue to the 1500-ft. level. The orebodies are larger and better at the 1200-ft. level than in the upper levels.

The Tenneseee, Union Basin, and Kingman Zinc companies continue to make their regular daily shipments. Many other properties will soon be added to the shipping list.

The Golconda Consolidated Mines, operating the Gem claims at Cerbat in the Wallapai district, 12 miles north of Kingman, and the Fredonia property at Golconda, about 1¼ miles farther north, is about to begin driving north on the 500-ft. level of the Gem on a vein which is four feet wide of good value. The drift will be advanced 200 ft. or more to catch the downward extension of what is known as the Ayers ore-shoot, which is credited with a past production of nearly $200,000 in the upper levels. There still remains on these levels a large tonnage of milling ore, upon which successful mill tests have recently been made, a total saving of from 85 to 87%, 80% by amalgamation. The ore extracted on the new levels will be treated in a reduction plant already on the ground, consisting of a 20-ton Nissen mill and concentrators. It is the intention of the management to increase the capacity of the plant to 50 tons daily as soon as conditions in the mines justify. It is also the plan to install at an early date a large compressor and machine-drills.

Yavapai County

Twelve miles south of Prescott is the Big Pine Consolidated company's property. Seven adits, No. 5 being in 1400 ft., have opened 70,000 tons of gold ore. A 100-ton mill, including rolls, tube-mill, and cyanide-plant is to be erected.

Yuma County

It is reported that for $1,000,000 cash, San Francisco people acquired the manganese property of E. E. Schellenger at the west end of the McCoy mountains. Estimates place reserves at 50,000 tons of 70% ore. Roads are being constructed to connect with the railway between Blythe and Blythe junction.

ARKANSAS

Searcy County

The first electric-light plant in the north Arkansas field was recently started at the Big Hurricane mine near Pindall.

The first shaft in the north Arkansas field is at the Bear Hill company's mine, five miles west of Yellville. A 250-ton mill is ready to crush the high-grade 'jack.'

CALIFORNIA

Operations in the San Joaquin Valley oilfields will for the next few weeks be confined largely to repairing the damage done by the recent wind-storms. The work of rehabilitation has already been actively commenced, and the weekly report of the State Mining Bureau clearly shows that it is going forward at the expense of proposed new work which falls considerably below the weekly average. Authentic reports of the storm damage indicate that nearly 2000 derricks were blown down, which is about 25% of the total number of producing wells in the San Joaquin valley. A small portion of the derricks were at idle or incompleted wells. February may therefore be expected to show a shortage in oil production over the entire State, amounting to possibly 40,000 bbl. per day, or over 15% of the recent monthly totals. Derricks can probably be replaced at a cost of about $400 each, or a total of about $750,000, of which about one-third will be spent for labor. There seems to be but little possibility of reconstructing the derricks to avoid similar loss in the future, and operators must find such comfort as they may in the fact that such storms are unusual. Increased drilling activity is to be expected in the next few months.

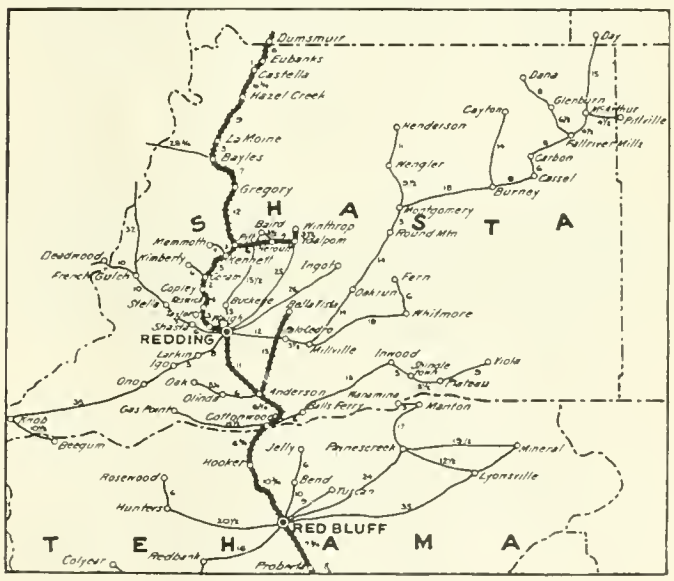
Amador County

Following are the preliminary figures of output and costs of the Plymouth Consolidated company in January:

Ore milled, tons	10,350
Value of output	$57,000
Working expenses	22,706
Development charge	7,465
Depreciation and construction	4,312
Surplus	$22,517
Other capital expended	110

Shasta County

(Special Correspondence.)—Some good ore has been opened in the Bell Cow mine, on Arbuckle mountain, and arrangements have been made to place the 10-stamp mill, formerly



SHASTA COUNTY, CALIFORNIA.

operated at the Gambrinus, near Stella, on the property. Frank Green and associates of Ono are operating the Bell Cow.

It is reported that a rich discovery has been made in the Midas mine, at Harrison Gulch. Good ore is going from the Midas and Gold Hill workings to the 20-stamp mill. H. L. Waste is superintendent.

Arrangements have been made to work the Sulphide group of copper claims near Copper City. It lies on the east side of the Shasta copper belt, and is controlled by W. T. Casson, of Carson City, Nevada, who is operating the nearby Shasta Belmont mine.

Redding, February 7.

Calaveras County

(Special Correspondence.)—The Columbia Mines Co. has been operating here about a year. A two-compartment shaft has been sunk to a depth of 250 ft. on an incline of 62°. At the 100-ft. level a drift has been driven 80 ft. At the 200-ft. level a drift is in 100 ft., and cross-cutting is now being done on that level. The property is equipped with a five-stamp mill, and compressor driven by electric power, also a gasoline hoist. The mine is situated in a line between the Melones and Gold Cliff properties.

J. S. Rear of Vancouver, B. C. is president of the company, and F. M. Woods of Colorado Springs, vice-president.

Angels, February 15.

Madera County

(Special Correspondence.)—The Kromonick Mining & Smelting Co., operating the Texas Flat and Waterloo claims, has decided to increase its capital from $60,000 to $250,000, for larger operations. All shares are held by Phillip Rowe and Maurice McMicken of Seattle, and H. A. Krohn of Coarse Gold, who have spent $100,000 in development and improvement. Three new shafts are to be sunk, and the treatment-plant will be overhauled.

Coarse Gold, February 1.

Sierra County

The Gold Star and Young America lode and gravel properties near Alleghany and Forest have been consolidated by S. L. Bright of San Francisco, and A. D. Foote, L. P. Larue, W. Hague, C. F. Clinch, and A. H. Tickell of Grass Valley. The new company is called the Mugwump Mines Company.

Yuba County

On February 16 the Marysville Dredging Co. launched its No. 5 boat at Marigold on the Yuba river, 10 miles east of Marysville. The dredge is generally similar to No. 14 of the Yuba Consolidated, having 16-cu. ft. buckets. It will be entirely motor driven. The Marysville company will soon have three boats at work; No. 1 and 2 are out of commission.

COLORADO

Clear Creek County

(Special Correspondence.)—Work has been resumed at the French Flag mine in Gilson gulch. The 200-ft. shaft is being unwatered. C. H. Ripley has secured a working fund of $50,000, and extensive development is planned.——A contract has been awarded for the extension of the Wyoming Valley adit, the present objective being the French Flag mine which lies 750 ft. distant.

The Friedman lease on the Edgar mine on Bellevue mountain shows a 5-ft. shoot that averages a mill settlement of $50 per ton in gold, silver, and lead. The mine is now capable of producing 100 tons daily.——The Boston Leasing Co., operating at the Edgar, and controlling ground below that of Friedman and associates, has followed a shoot in the 100-ft. winze that varies from 1 to 5 ft. width. Recent shipments have given $40 per ton. The Hudson mill is treating 100 tons in three 8-hour shifts. A. H. Roller is manager.

The Jackson mill will probably pass over to J. P. Ruth within the next 30 days, the consideration being given at $25,000.

Hawes and company, leasing at the Golden Edge mine through the Argo adit, have cut a two-foot shoot of smelting ore that is yielding $70 per ton in gold and silver.

Shipments of mill and smelting ore are going out from the Lake mine operated under lease by the I. D. L. Co. G. K. Kimball is manager.——Shipments have been started from the Black Eagle mine on Chicago mountain. The yield is $25 per ton.

Idaho Springs, February 5.

San Juan County

The Silverton district has been little heard of lately, but this is due to the enormous fall of snow late in January, and only recently were trains able to get to the town.

Summit County

At 1000 ft. depth in the Wellington mine at Breckenridge the Great Northern vein is 12 ft. wide, averaging 42% zinc.

Teller County (Cripple Creek)

During 1915 the Doctor-Jack Pot Mining Co. shipped 14,382 tons of ore worth $19.98 per ton. Including lessees' royalties of $38,766, the profit was $47,271.

IDAHO

In his report for 1915, the State mine inspector, Robert N. Bell, discusses the prosperous conditions of the industry, with special reference to the Coeur d'Alene region, the lead districts of Gilmore, Dome, and Wood River, the Seven Devils copper district, and the phosphate deposits.

Clearwater County

Development of the Richmond mine near Adair continues at a good rate, opening copper carbonate ore. A shipment of 150 tons averaged 8.87% copper and $4.80 per ton in gold. When the lower level is completed reserves will be increased to 40,000 tons. A wagon-road is being constructed, but an 8000-ft. aerial tram is to be ordered.

Shoshone County (Coeur d'Alene)

During January the Caledonia mill treated 3036 tons of ore, yielding 894 tons of concentrate; 548 tons of crude ore was shipped. Metal contents were 885,740 lb. lead, 133,347 oz. silver, and 79,402 lb. copper, worth a total of $149,315. The net profit was $100,264.

MISSOURI

Jasper County

On February 5 the A. W. C. Mining Co. sold 1000 tons of zinc-blende to the Granby Mining & Smelting Co. at $117.50 per ton. As the concentrate assayed 63% metal, a total of $121,000 is expected in settlement. The smelting company also purchased 500 tons from the Carmean & Squires company for about $55,000. The A. W. C mine is on west 7th street, Joplin. It has three mills working, and the above product was nine weeks' work. The Carmean & Squires has five mines in sheet-ground around Webb City. Its output was from two weeks' operations.

Remarkable activity is reported from the South Carterville area. Five mills have been built since September, five others are under construction, and others are proposed. The Zinc Corporation of Missouri is the most important property.

For $125,000, the interests of C. R. Strong in the Dick Turpin mine, west of Joplin, were purchased by Senator E. Wilkerson of Kansas. Mining is done in sheet-ground from 180 to 200 ft. deep. A new motor-driven 350-ton per shift mill is part of the equipment.

The large flow of water in the north Webb City sheet-ground district requires heavy pumping, although the mines continue to operate.

MONTANA

Fergus County

The January clean-up of the Barnes-King Development Co. was $53,078.

Phillips County

(Special Correspondence.)—The eastern half of Montana is mostly level country and generally devoid of conspicuous topographic features. A number of small buttes rise above the plains, and here and there rise small groups of mountains. The Little Rocky mountains form such a group. They are in Phillips county, between the Missouri and Milk rivers. They are 10 miles long and 8 miles wide, the longer axis trending north-east. The highest peaks are about 6600 ft., while the surrounding country is approximately 3000 ft. above sea-level. The range is 35 miles south of the Great Northern railway, and directly south of the Fort Belknap Indian reservation. The principal mining centres are the Ruby Gulch at Zortman, the August mine at Landusky, and the Beaver Creek on Beaver creek.

The Ruby Gulch cyanide mill is in the heart of the Little Rockies. Its capacity is 600 tons per day, and it was built in 1905. Electricity is employed to operate the machinery. An adit has been driven into the mountain for a distance of about two miles, and all hauling is done on this by electric locomo-

tives. The power-plant of the Ruby Gulch is situated on the bank of the Missouri river, 35 miles from the mill. One hundred and forty men are employed. Mining and milling the ore costs the low figure of 98c. per ton. The bullion is hauled to either Malta or Dodson by autos; thence to Helena. The shareholders of the Ruby Gulch mill, B. D. Phillips, B. M. Phillips, Charles Whitcomb, A. L. Smith, and W. Woods are contemplating doubling the capacity of both the power-plant and mill in the near future.

The August mill at Landusky is also working at capacity and treating about 500 tons of ore daily, assaying from $4 to $20 per ton.——The Beaver Creek mine, like many others in the adjacent district is producing ore in commercial quantities.

Zortman, January 25.

Silverbow County

At the Pennsylvania mine at Butte, where the fatal fire occurred last week, all of the victims have been found and the fire is under control. Ten horses were asphyxiated. The Anaconda company's loss will be heavy. Relatives of twenty-one men will receive $4000 each, spread over 400 weeks, or $3380 in a lump sum. The damage to the mine will entail a large expenditure.

The North Butte Mining Co. reports that during the last quarter of 1915 development totaled 5224 ft. The principal work was opening the Sioux Chief vein at 700 ft. Where cut it was 4 ft. wide of 5.3% copper and 2.5 oz. silver, and 13 ft. of 2.9% copper and 2 oz. silver. The Granite Mountain shaft was sunk 74 ft., and a large skip-chute cut at 3000 ft. Results generally on the Edith May, Hancock, Jessie, South and North Croesus veins was satisfactory. There was treated 123,555 tons of ore and 9.7 tons of copper precipitate, yielding 5,713,746 lb. copper, 366 oz. gold, and 256,695 oz. silver.

NEVADA

During 1915 the Nevada Industrial Insurance Commission received $560,248. Compensation amounted to $134,071. Nye County employers contribute 24% of the income, followed by White Pine, Esmeralda, and Washoe.

During February and March dividends amounting to $463,050 will be paid by companies in this State, as follows: Jim Butler, $171,802; Jumbo Extension, $116,250; Prince Consolidated, $25,000; Reorganized Booth, $49,998; and Yellow Pine, $100,000.

Clark County

Every mine at Goodsprings is being worked either by companies or lessees; prosperity is evident on all sides. The Yellow Pine company's mill produced zinc concentrate that allowed of $450,000 being paid in dividends last year, making $983,008 to date. There are also three 60-ton and one 30-ton mills at work. Prospects at the Boss platinum mine are good.

Humboldt County

(Special Correspondence.)—The Rochester-Packard Annex Mines Co. which was recently incorporated with W. P. Hartman, president and general manager; W. B. Moynagh, vice-president, and superintendent; Alex. Egenes, secretary and treasurer, C. J. Abrams, consulting engineer; and M. Moynagh, John E. McGovern, W. B. Borland, J. W. Kremer, and L. H. McGarrah directors, owning seven full claims between the property of the Rochester Mines Co. and the Nevada Packard company, has been developing since December 9, 1915. Two adits have been driven to cross-cut veins that assay well on the surface. The A adit will give a vertical depth of more than 900 ft. on the veins. The B adit, intended principally for prospecting purposes, is 250 ft. above the floor of the canyon, that cuts through the property. It has penetrated a 21-ft. vein of mixed quartz and rhyolite of low-milling value. The adit being continued through the rhyolite hanging wall to intersect a large vein farther west which carries high silver content, in bromide and chloride form on the surface, has cross-cut a two-foot vein, which, according to assays at the Lovelock assay-office carries $48.80 gold and $28.61 silver per ton. This was a surprise to the management. It appears from its trend to be a branch or spur connecting the veins mentioned. No driving has been done on either vein, but when the objective point is reached by the adit, driving will be started on all of them. All ore extracted is being saved, and will be treated at the Nevada-Packard mill. The necessary equipment is either on the ground or in transit, and development will be pushed as rapidly as possible in order to block-out sufficient ore to justify the construction of a mill.

Rochester, February 1.

Nye County

The Nevada Cinnabar Co. at Ione is treating 50 tons of 2% quicksilver ore daily.

Last week Tonopah mines produced 8700 tons of ore worth $181,860.

During January the Belmont made a profit of $86,564 from 12,863 tons of ore. The Jim Butler's profit from 4682 tons was $28,746. The Tonopah company's mill treated 7413 tons for $27,270 profit, a large decrease. The Extension is to pay 10c. per share.

Certain ground of the MacNamara mine is to be developed from the West End workings, an agreement having been made to that effect. Good results are expected.

White Pine County

In the Press of January 29 it was stated that tungsten was discovered in this county by Charles Gaby 17 years ago; also that G. G. Sims found hübnerite in the Eagle district 6 years ago. According to M. E. Bassett of Aurum this discovery is a re-discovery on the part of Sims, as Bassett discovered and worked the principal claims credited to Sims in 1873, with his brother. Sims did not at that time know of tungsten, but claims that it was not his fault as samples were pronounced by local assayers to contain zinc in place of tungsten. The ore carried $50 silver, and some lead and still carries these metals.

TEXAS

Brewster County

(Special Correspondence.)—The old Marfa & Mariposa Mining Co., a pioneer in the production of quicksilver in this State, will re-open its properties about February 1, under the management of Alfred A. Newell who was associated with the company for several years prior to closing-down on account of the low prices of metal then prevailing.

The Study-Butte Mining Co., which recently re-opened the Big Bend quicksilver properties, has its furnace working, and reports the property is opening well.

There is some talk of other properties in the district re-opening in the near future.

Terlingua, January 25.

UTAH

Beaver County

For some unknown reason the U. S. S. R. & M. Co. has stopped work indefinitely at Fortuna. Gold-bearing ore has been opened, but the two claims rather limit operations. The McGarry-Hodges lease on the ground has 400 tons ready for treatment at the Sheep Rock mill, five miles east.

Boxelder County

On February 5 the Lakeview Mining Co., of Ogden, operating at Promontory, will probably pay 3c. per share, equal to $15,000. The present output is a carload of zinc ore every other day. The mine manager, Samuel S. Arentz, has made a report for the term August 1, 1915, to January 1, 1916. Production has been from an area 200 ft. along the strike and 200 ft. on the dip, from the surface above No. 4 workings to the bottom of shallow winzes below No. 3 adit. Development

as done at other points. Ore is not confined to the upper meshale contact. Ore is exposed in the face of No. 4 adit, early 400 ft. from the portal. In about 10 weeks, when ertain work is finished, the output of 800 tons per month will e increased. Lessees and sub-lessees have done considerable ork. Generally, the orebodies are persistent, and the future good. According to the business manager, W. A. Perkins, July 31, 1915, 981 tons of ore returned $26,853 net. From at date to the end of 1915 the company and lessees shipped 044 tons, giving $117,681 net, a total of $144,537. Dividends bsorbed $57,000, and wages, $22,903, while other charges made total of $107,880. On January 1 cash on hand amounted to 16,983. The A. S. & R. Co. held an option on the property or $625,000, but this was not completed.

A preliminary survey is under way for a five-mile narrow-auge railway from Salina, on the Union Pacific, to the Lake-lew mine.

Juab County

The report of the Chief Consolidated Mining Co. for 1915 has een issued. The superintendent, Cecil Fitch, states that evelopment totaled 6690 ft., down to 1800 ft. depth. Results ere fair. The output was 36,412 tons of ore containing 4634 z. gold, 403,854 oz. silver, 8,232,606 lb. lead, 5648 lb. copper, nd 622,465 lb. zinc. The average gross value was $20.55 per on. Sampling, freight, and treatment cost $10.59. The net rofit was $122,414. Two dividends absorbed $88,053. Cash n hand at the beginning of 1916 was $210,034, an increase of 23,286.

The May Day company pays 3c. per share on February 26, qual to $24,000.

Improvements to the Utah Minerals Concentrating Co.'s lant have made a 250-ton capacity possible.

Good zinc ore is being extracted from the Bullion Beck, New Bullion, and East Tintic Development mines.

From its Homansville claims the Chief Consolidated com-any is to mine manganese ore which averages 43% metal.

Salt Lake County

'A Reconnaissance of the Cottonwood-American Fork Min-ng Region, Utah,' is the title of U. S. Geological Survey Bulletin 620-I, by B. S. Butler and G. F. Loughlin, with notes n history and production by U. C. Heikes. A reproduction of he geologic map will appear in an early issue of the Press. The altitude of the area is from 5000 to 11,500 ft.; Alta, around which are the principal mines in Little Cottonwood canyon, is 700 ft. high. Recent glaciation is strongly evident. Heavy nowfall interferes with winter work. Snow-slides are a men-ace since the timber was cut. Water is abundant for all pur-oses. Ore was first discovered in Little Cottonwood in 1864. Some early smelting was done, and a concentrating mill vorked at the Emma in 1874. The Big Cottonwood district vas organized in 1870, as was also the American Fork. From 867 to 1913 inclusive, the Cottonwoods produced 21,474 oz. old, 10,778,917 oz. silver, 7,323,726 lb. copper, and 138,477,448 b. lead, worth a total of $20,652,910, from 302,159 tons of ore. Large dividends were paid. In the same years American Fork ielded 12,869 oz. gold, 1,791,987 oz. silver, 104,663 lb. copper, 7,328,628 lb. lead, and 2712 lb. zinc, valued at $3,716,018. The nain types of deposits are contact, fissure, and bedded, of com-non origin, showing complete mineralogical gradation. At everal places contact deposits pass into fissure deposits.

The South Hecla Mining Co. has issued its report for 1915. Exploration covered 222 ft. of shaft-sinking and 1353 ft. of driving; the total is now nearly 25,000 ft. Development of ore was mostly confined to the Wedge vein. Five blocks of ground were let to lessees. Regular ore shipments commenced n August. The company and lessees produced 3478 and 1306 ons respectively, containing a total of 161 oz. gold, 144,066 oz. silver, 914,491 lb. lead, 507,842 lb. zinc, 33,151 lb. copper, and 399,905 lb. iron, yielding a profit of $39,206. Cash on hand amounted to $36,524 on January 1, 1916, with $6648 bills payable.

The North Star, South Star, Silver Star, and Lucky Star claims of 30 acres, owned by Moylan C. Fox, were purchased last week by the Emma Copper Co., which now has 69 acres. Possible litigation has been avoided by this transaction.

WASHINGTON

Mining companies operating in the northwestern territory tributary to Spokane, by March 1 will have paid $1,446,173 in dividends for the current year, increasing the grand total of the corporations now distributing dividends to $66,183,430. Of this amount the Coeur d'Alene concerns will have distributed $983,750 for 1916, making the total $51,875,896, and British Columbia will contribute $462,423 for the year to that date, making the aggregate disbursements $14,307,534.

Stevens County

While the Bunker Hill & Sullivan company will soon begin shipping ore to the smelter at Northport, there is nothing in this bearing on the company's smelter-construction plans, according to word received in Spokane from Stanly A. Easton,

PART OF MONTANA, IDAHO, WASHINGTON, AND CANADA, SHOWING SITUATION OF THE COEUR D'ALENE REGION, THE NEW SMELTER AT NORTHPORT, AND THE SMELTERS IN BRITISH COLUMBIA.

general manager at Kellogg. The material to be sent to Northport is for fluxing purposes, high in iron and containing from 7 to 8% lead. Quantities of this grade have been dispatched to different smelters in the country for years, and it in no way violates the contract with the American Smelting & Refining Co.; in fact, it is a grade of ore this concern does not want, and is a sort of waste product that the Bunker Hill is glad to dispose of anywhere it can. At the request of the Northport Smelting company it is to be sent to the new plant.

The smelter at Northport, being constructed by the Northport Smelting & Refining Co., financed by the Hercules and the Tamarack & Custer mining companies of Idaho, will be ready to blow-in on March 1, according to H. V. Croll of Allentown, Pennsylvania, sales engineer for the Traylor Engineering Co., who was in Spokane recently after spending four months at Northport superintending construction and installation of equipment. The plant, which will represent an ex-

penditure of approximately $500,000 when completed, is of the most modern type. It is provided with all labor-saving devices, and should prove highly efficient. Practically nothing remains of the old plant, and that part utilized in the new construction has been entirely re-built. The equipment consists of two lead furnaces 42 in. wide and 16 ft. long, with a smelting column 18 ft. high. Each has a capacity of 250 tons of ore daily, or 15,000 tons per month, and it is thought that this will be adequate to deal with the ores of the allied Coeur d'Alene properties that will supply the material. In addition, three of the six copper furnaces used in the former plant have been renovated for operation at any time, but this may not be for several months. Four Dwight-Lloyd sintering-machines have been installed, an entirely new crushing and automatic sampling-plant built, and a new charging system has been devised, including pit, cars, trackage, and other accessories. All the ore is carried by belt-conveyors. The changes in the system have necessitated a re-arrangement of the railway-tracks serving the plant, and this has caused delay in beginning operations, as the furnaces are ready for their charges as soon as the cars carrying the concentrate can be transferred to the unloading bins. The cold weather has interfered with constructing the new spurs and sidings, and it is not possible to have the track connections completed in less than 30 days. The material from the mines will reach the smelter in the shape of concentrates, both coarse and fine, together with the slimes as they come from the mills. The concentrates are crushed to particles averaging one-fourth inch, and, when mixed with the slimes, are sent to the sintering-machines. Their product is broken into smaller pieces and sent in cars to the charging-pits, where the sintered material is mixed with coke, limestone, iron, and oxidized ores, drawn from adjacent bins in which this is stored. A locomotive then is attached to the car, pushing it into the top of the charging-furnace, where it discharges its load, averaging four to five tons. The resulting lead bullion will be molded into pigs, averaging about 100 lb. each, sampled, and then loaded into railway cars for transportation to the Pennsylvania Smelting Co.'s refining plant at Carnegie, which has been taken over by the Northport company.

Ferry County

(Special Correspondence.)—The mill, machinery, and other buildings of the North Washington Power & Reduction Co. were recently sold by W. S. Bailey, trustee in bankruptcy, to R. E. Clark, of Spokane, for $6500, to satisfy the claim of the Chicago Title & Trust Co. This property had been previously sold to the same buyer for $25,000 but reverted on default of payments after about $8000 had been paid.

A 225-hp. Bessemer oil-burning engine has been installed at the Surprise mine by the Republic Consolidated Mines Corporation, which expects to operate on a more extensive scale and sink to 1000-ft. depth. The shaft of the Lone Pine mine will be sunk 100 ft. to 400 ft. depth.

In the San Poil district, W. E. Malm, engineer for the Walla Walla Mining Co., operating at Keller, has finished surveys and will soon install machinery and a diamond-drill to prospect the company's property.

High-grade scheelite is reported to have been found in the Silver Leaf mine, situated 1½ miles west of the Columbia river, in the Troy district. The property is under bond to James Keith, of Spokane, who is said to have shipped 15 tons of ore to the Granby smelter, containing about 200 oz. silver per ton. The report is confused by the statement that the smelter paid $1 per pound as advance settlement.

Republic, February 10.

Pierce County

The duplicated refinery at the A. S. & R. smelter at Tacoma is complete at a cost of $750,000. Its capacity is 6000 tons of metal per month. There was no increase in the smelting capacity.

PERSONAL

Willet G. Miller is on his way to London.

F. W. Bradley is to visit Kellogg, Idaho, early in March.

A. J. Eveland, recently at Pachuca, has gone to South America.

H. W. Turner has been examining quicksilver deposits in Lake county.

John T. Reid has recently returned to Lovelock, Nevada, from New York.

W. Motherwell has gone to the Santa Gertrudis mine, Pachuca, Mexico.

G. F. Trethewey is now manager of the West Dome mine, Porcupine, Ontario.

Fred Searls and Karl Hoffmann are accompanying W. W. Mein on his professional journey to South Africa.

R. R. Leslie, manager of Butters Divisadero Co., is expected to arrive in San Francisco early in March.

George E. Farish is now at Oatman, Arizona. He expects to return to New York during the first week in March.

Clayton L. Kohlhaas, Michigan College of Mines, 1910, is with the Denver Rock Drill Co., at Houghton, Michigan.

Robert M. Betts, manager of the Cornucopia Mines, has been examining quicksilver properties in southern Oregon.

Robert E. Cranston has been placed in charge of the gold-mining department of the Anaconda Copper Mining Co., at Butte.

C. H. Shoemaker, general superintendent for the Asbestos & Asbestic, Ltd., has returned to Asbestos, Quebec, from Arizona.

James Richards, superintendent of the Isle Royale mine, Michigan, is in Florida on an extended vacation for his health. A. H. Wohlrab is acting superintendent during Mr. Richards' absence.

W. W. Mein sailed on February 26 by the *New Amsterdam* for London, on his way to the Rand, where he will report on some important mines.

Atkins, Kroll & Co. have resigned the management of the Atolia Mining Co. E. C. Voorheis has been appointed general manager with headquarters in the Humboldt Bank building, San Francisco.

Schools and Societies

Copper companies operating in Arizona have contributed $100,000 towards the construction of a school of mines at the State university at Tucson. There is also available $75,000 appropriated by the last Legislature.

The Montana Section of the A. I. M. E. held its annual meeting at Butte on February 4. There were 49 members and guests present. The following officers were elected for the ensuing year: chairman, J. L. Bruce, manager of Butte & Superior Copper Co.; vice-chairman, W. C. Siderfin, manager W. A. Clark interests in Montana; secretary-treasurer, M. H. Gidel, assistant geologist Anaconda Copper Mining Co.; and executive committee, N. B. Braly, superintendent of mines of the North Butte Mining Co., and W. T. Burns, superintendent of electric refinery of the Boston & Montana reduction works, Great Falls. Following the banquet, a paper entitled 'Present Status of Oil Prospecting in Montana' was read by D. C. Bard, who is joint author of the paper with Chester Steele. Frederick Laist of the Anaconda company gave a talk on the metallurgy of zinc, explaining briefly the method employed by the company for the treatment of complex zinc ore from the Butte district. The secretary's report shows 177 active members in the State, an increase of 17 over that of last year.

THE METAL MARKET

METAL PRICES

San Francisco, February 23

Antimony, cents per pound	41
Electrolytic copper, cents per pound	27.75
Molybdenum, 90% MoS_2, per pound	$1.40
Pig lead, cents per pound	6.55—7.50
Platinum soft metal, per ounce	$85
Platinum hard metal, 10% Iridium, per ounce	$89
Quicksilver per flask	$300
Spelter, cents per pound	22
Tin, cents per pound	43
Zinc-dust, 100-kg. zinc-lined cases, cents per pound	30

ORE PRICES

San Francisco, February 23.

Antimony, 50% product, per unit	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	11
Magnesite: crude, per ton, f.o.b.	8
Magnesite: plastic, no iron and lime, calcined, per ton	30
Magnesite: refractory, 11% iron, dead-burned, per ton	35
Manganese: 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten, minimum 60% WO_3, per unit of 20 lb.	60—65

New York, February 18.

Antimony, per unit	$2.50
Tungsten, per unit	70
Manganese: 50%, per ton	90

Carlisle & Company, 74 Broadway, New York, have prepared for free distribution a booklet entitled 'Tungsten, Its Properties and Uses.' It is very complete and contains extracts from the U. S. Geological Survey.

The February issue of 'The Pahasapa Quarterly' (South Dakota School of Mines) is a tungsten number and worth securing.

EASTERN METAL MARKET
(By wire from New York.)

February 24.—Copper is quieter though strong, prompt metal is scarce; lead is quieter; there is a good demand for zinc of choice grades.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The silver market continues steady. European coinage orders continue to be the chief support, though England and India have been buyers. Stocks at Bombay are lower, and Bazaar support is probable. Shipments of silver from London to India to February 2 were only one-sixth of those of last year.

On February 18, silver worth $356,590 (say 630,000 oz.) was shipped from San Francisco to China.

The zinc ore market at Joplin was strong last week, the top price being $130 per ton for 60% product. The output of the Missouri-Kansas-Oklahoma region was 7674 tons blende, 381 tons calamine, and 924 tons lead, averaging $112, $87, and $84 per ton, respectively. The total value was $973,672, and for seven weeks $5,708,908.

Tin is firm at 42.50 to 42.75 cents.

ALUMINUM

A growing scarcity of stocks and a more active demand has caused quotations to advance, and 57 to 60c. is now quoted for No. 1 virgin aluminum, 98 to 99% pure.

Antimony imports into the United States during 11 months of 1915 were 2,334,003 lb. in ore, and 14,477,162 lb. metal, compared with 1,787,922 lb. and 12,079,613 lb. in that period of 1914.

Eastern Metal Market

New York, February 18.

Conditions in the metal market are such as never before existed, especially with regard to copper. Prompt metal has sold at 29.62½c., the highest in 43 years. There is a strong and sustained demand for second-quarter deliveries, which range from 27.25 to 27.50c., March also being in good request. Conservative sellers fear that the price may go too high to be healthy, if it is not there already. Never before, however, was there such a demand to stimulate buying. London continues high and strong, and foreign stocks continue to decrease. Zinc is advancing under the stimulus of a good demand which is calling more for future positions. Foreign buying of lead is heavy, and explains an advance of $1 per ton, despite comparative inactivity on the part of home consumers. The tin market has pursued a serene course, despite the dangers of the times. Supplies are arriving in good volume, and business has been good in the past week. Antimony is scarce and strong, the only feature being that plans have been perfected to care for the requirements of jobbers. Aluminum is again advancing because of its scarcity.

There seems to be no end to the demand for steel, and in numerous lines of products there have been further price advances. The mills are turning-down business, even when it is offered at premium prices. The total of iron and steel exports for the calendar year 1915 was 3,513,453 gross tons, compared with 1,540,574 tons in 1914, and 2,730,483 tons in 1913. Machinery exports in December, 1915, totaled $13,228,450, against $6,372,041 tons in the same month of 1914; and for the calendar year 1915, totaled $134,128,862, compared with $91,818,664 in the preceding year.

COPPER

Not since 1873—43 years ago—has copper been so high as it is today; in that year the average price was 29c. per lb. In the past week prompt electrolytic has been sold at 29.62½c., New York, and there is nothing to indicate that the top notch has been reached. The conservative element of the trade is not only wondering when the advances will cease, but is actually worried over the abnormal situation. They point out that the greater the height, the greater will be the fall, and they are afraid that men's minds may run away as well as the market. The London market for electrolytic was quoted on February 16 at £136 10s. Statistics cabled to the New York Metal Exchange give the combined stocks of Great Britain and France, as of February 15, as 8777 tons, against 9998 tons, January 31, a decrease of 1221 tons. In this market spot and near-by is difficult to obtain even when fancy premiums are offered. Most of the business continues to be in second-quarter deliveries which can be had at about 27.25c., 30 days, delivered. For prompt metal 29.62½c. appears to have been the highest figure paid, while some has been taken at 29.50c. The buying bas been almost entirely of electrolytic, over which the price of Lake ranges slightly, but its quotation is nominal. For deliveries to the end of the year, 27c. has been quoted. Positions from prompt to June, range from 29.50 down to 27c. March and April electrolytic has sold at 28.50c., and May at 28c. The steady buying has been mostly on account of the manufacturers of war munitions. Industrial consumers have yet to come into the market to a considerable extent. It is stated on good authority that the largest producer of brass and copper goods is turning out its products at the rate of 2,000,000 lb. every 24 hours, and it is safe to assert that most of this is for war purposes. John D. Ryan states that the demand up to the present time has been such tbat the Anaconda company's product is sold ahead for a longer period than ever before. Exports, February 1 to 17, totaled 8805 tons. Exports in January totaled 23,663 tons, against 26,193 tons in that month of 1915.

ZINC

The market has been continuously firm, with an active demand for February, March, and April metal. Seemingly there are more buyers than sellers of these positions, and this has had the effect of accentuating the demand. The London market was strong, February 16 at £99, having advanced £6 the preceding day, and lending corresponding strength to the New York market. Futures have been more active, a pleasing fact to producers, inasmuch as some of them are entirely sold out for the first quarter, and have been for some time. Second-quarter deliveries now range from 18 to 18.25c., St. Louis. Prompt metal was quoted on February 17 at 21c., New York. With all the activity the operations of the sheet galvanizers continues at low ebb, not much above 50% of capacity. John D. Ryan states that the Anaconda company's new electrolytic zinc plant is a success, and that its product has been sold for a year ahead at a profit of about $4,000,000, and that the company is erecting a plant with a capacity of 10,000,000 lb. of zinc per year, which probably will be in operation next fall. Exports of zinc this month, including February 17, total 1806 tons. Sheet-zinc is unchanged at 24 cents.

LEAD

A strong demand from abroad, with buyers willing to pay premiums, preceded an advance of $1 per ton, or to 6.30 per lb., New York, which was announced by the A. S. & R. Co. on February 16. Russian interests have taken large quantities, and other European countries have been good buyers as well. The strange feature of the situation is that the domestic demand has been almost dull, a phase which sellers are unable to understand. They say if domestic consumers believe they can cause the market to come down by remaining aloof from it they are doomed to disappointment, as long as the present heavy foreign demand continues. The St. Louis market is strong at 6.22½c. The indications point to still higher prices. Exports this month, including February 17, total 4109 tons.

TIN

Of this metal there is little to say, except that there has been some heavy buying in the past week, various days having seen aggregate sales of 250, 500, 600, and 800 tons. With the activity, prices advanced, but in no abnormal way. From 41.12½c., on February 9, quotations gradually went up to 42.12½c., on the 16th. An interesting circumstance is that the steamship *Bolton Castle*, which, with two other steamers, was partly destroyed by fire while lying at a Brooklyn pier this week, had but a short time previously discharged 1300 tons of tin. Supplies continue to arrive freely, despite what is now regarded as a precarious journey. Arrivals of the month, including the 16th, total 3567 tons, and there was afloat on that day 5118 tons.

ANTIMONY

Since the last report a plan has been accepted whereby jobbers in antimony can continue to do business. It provides that stocks may be carried in public warehouses in the name of the British Consul, and that these may be drawn upon in any quantity when the jobber presents to the Consul a satisfactory guarantee from his customer. The consumer must stipulate that the antimony wanted is for his own manufacturing needs, that he will not re-sell, or ship products abroad without the consent of the Consul. The price is unchanged at 43.50 to 45c., duty paid, for prompt, metal is scarce, despite some rather large recent arrivals. These, however, had been sold while afloat.

COMPANY REPORTS

NEVADA CONSOLIDATED COPPER CO.

The report of the Nevada Consolidated Copper Co. for the last quarter of 1915 has been issued. The mill treated 830,157 tons of 1.59% ore, 92% from the pits, and 8% from the Ruth mine. In addition there was treated 22,027 tons from the Giroux mine. The yield was 18,287,930 lb. copper, at a cost of 7.45c. per lb. Metal was sold at 21.699c. per lb. Total net earnings were $2,739,196. Dividends absorbed $999,728, depreciation, $142,724, and ore extinguishment $82,228, leaving a surplus of $1,514,516. Assets include metals at all points $4,998,829, and cash $341,120.

BUTTE & SUPERIOR COPPER CO.

The last quarter's (1915) operations of this zinc producer show the following results:

	Quarter.	Year.
Ore treated, tons	150,150	522,300
Recovery, per cent	95.07	92.06
Zinc production, pounds	47,563,144	163,956,791
Cost of mining and milling, per ton	$5.13	.....
Net income	$3,093,798	$9,125,942
Net per share	.....	$33.92

The output of metal for the year was an increase of 56,128,112 pounds, net income $7,708,814 more, and net per share $28.71 greater. Ore reserves are approximately the same as before.

CHINO COPPER CO.

The report of Chino Copper for the last quarter of 1915 contains the following data:

Overburden removed, cubic yards	833,695
Ore treated, tons	691,200
Average content, per cent	2.11
Extraction, per cent	66.92
Metal output, pounds	19,560,245
Cost per pound, cents	7.20
Average price received, cents	20.476
Profit	$2,461,716
Dividends	869,980
Surplus	$1,591,736

Dividends increased $217,525, and the surplus $688,777.

RAY CONSOLIDATED COPPER CO.

The report of Ray Consolidated for the last quarter of 1915 includes the following:

Ore treated, tons	797,102
Average content, per cent	1.688
Metal from all sources, pounds	17,195,533
Cost per pound, cents	9.625
Price received, cents	20.213
Profit	$1,807,983
Dividends	777,482
Surplus	$1,001,085

The daily ore tonnage was 879 greater than in the previous term, and the yield was 2,260,000 lb. more. The profit was more than double. The year's total of 62,541,196 lb., was an increase of 3,496,496 pounds.

MT. MORGAN GOLD MINING CO.

This Australian company has issued its report for the half-year ended November 28, 1915. The general manager, A. A. Boyd, states that the mine was worked for 155 days, during which time 2868 ft. of development was done, and 203,767 tons of ore extracted down to the 950-ft. level. The average was 1290 tons per day. There was also mined 98,202 tons of waste for filling stopes, silica, smelting ore, and flreclay. Reserves are estimated at 999,393 tons of high, and 1,723,364 tons of medium-grade ores.

Two blast-furnaces worked continuously, but owing to higher silica content costs increased. The plant treated 119,051 tons of ore, 18,431 tons of concentrate, 25,197 tons of pyrite ore, and 188 tons of other material, 162,867 tons in all. This yielded 9,654,400 lb. of copper, and 62,779 oz. gold. The average was 2.647% copper and $7.70 gold per ton. The concentrator treated 83,985 tons of ore for 24,023 tons of concentrate, with 88.49% recovery of the copper, and 72.58% of the gold.

Total working costs were $10.20 per ton. The revenue was $3,092,000, and profit $800,000, of which $720,000 was paid in dividends. The surplus is $970,000.

UTAH COPPER CO.

The report of Utah Copper for the last quarter of 1915 shows the following:

Overburden removed, cubic yards	1,651,860
Ore treated, tons	2,384,364
Average content, per cent	1.4694
Extraction, per cent	63.11
Metal produced, pounds	44,224,715
Cost per pound, cents	6.10
Price received, cents	21.408
Profit from all sources (including Nevada Con. dividends)	$6,919,203
Dividends paid	2,436,735
Surplus	$4,482,468

The output for the year was 156,207,376 lb., against 121,779,401 lb. The surplus is $1,692,395 greater.

JIM BUTLER TONOPAH MINING CO.

The report of this Nevada company is for the year ended September 30, 1915. The general superintendent is Frederick Bradshaw of the Tonopah Belmont Development Co., who states that the period was the most profitable of any, in spite of lower-grade ore, which was mostly due to the lower price for silver.

Mine development amounted to 8569 ft., of which 4460 ft. was in the Desert Queen, and 4199 ft. in the Wandering Boy, at an average cost of $7.482 per foot, a decrease of 42c. This work resulted in the development of 45,424 tons of new ore. Reserves are estimated at 40,310 tons, a decrease of nearly 10,000 tons, but future prospects are good. A considerable amonnt of construction was done at the Wandering Boy shaft. The Ophir King claims were purchased during the year for $1750. They have an area of 92 acres.

The Belmont mill at Millers treated 48,146 tons averaging 0.301 oz. gold and 26.42 oz. silver per ton at a cost of $5.02. The metal recovered was 13,544 oz. gold and 1,158,335 oz. silver. A new and more favorable treatment contract has been arranged.

The net revenue from all sources was $506,086; expenditure, $319,365; dividend No. 1, $171,802; and cash at September 30, 1915, $250,698. The balance at the end of the previous term was $235,780.

Operating costs were $10.46 per ton, a reduction of $1.87. Mr. Pike is mine superintendent, and Mr. Robins, engineer.

The Isabella Mines Co.'s report for 1915 shows that development totaled 17,289 ft., 1590 ft. by the company, 8368 ft. by company lessees, and 7331 ft. by royalty lessees, a large increase. At 1275 ft. depth good ore is being extracted. The output was 24,698 tons of ore worth $507,792. The company's net earnings were $43,573, and surplus $85,999. Lessees are operating the mill on dump ore.

EDITORIAL

T. A. RICKARD, Editor

ANNOUNCEMENT is made that the Northwest Mining Convention will meet at Spokane on March 20 and the five days thereafter.

"COPPER reaches £92," we read in *The Financial Times* of February 1. This causes a mental jar, until we realize that the London quotation, equivalent to 19.92 cents per pound, is for 'standard' copper, an impure brand containing about 97% metal. The retention of an obsolete term like 'standard' for low-grade copper seems unnecessary and objectionable.

STATISTICIANS have a hard time, when conscientious; but most of them sleep easily, having few qualms. To the real student of figures we give a warning. At the present time Mexican pesos are being brought into this country for sale as bullion and are finding their way to the mints. Again, small lots of bullion stolen from Mexican mines are being shipped to American smelters, even as far from the border as Pennsylvania. Any of these consignments of silver will vitiate the statistics of domestic silver production unless care is taken.

AT this season of the year a great deal of mining machinery is bought for immediate use. It is required for unwatering workings, for resuming work in open-cuts, for starting new enterprises. We recognize the timely interest of the subject by publishing comment and criticism of various types of machinery, endeavoring always to obtain it from unprejudiced sources, neither from the manufacturer nor from his rival, but from the mine-managers who use the machinery and are willing to give information useful to other managers. Such information is difficult to obtain for publication, although freely circulated as gossip. A great deal of mining is wasted for lack of detached criticism; it will never be possible to obtain much of it for publication, but such of it as is made carefully and fairly is of inestimable value.

IN a recent issue we referred to the Mexican branch of the Industrial Workers of the World, commonly known as the I. W. W., a socialistic, but anti-social, organization. This Mexican branch is called *La Casa Obrero Mundial;* it has become obstreperous; a general strike was threatened to begin on February 27 unless an increase in wages equivalent to 60% gold was granted. Whereupon the Government made it known through General Fredo Rodriguez, at Mexico City, that any interference with public order would be met by force. The workmen were warned against an attempt to paralyze industry by a general strike and they were advised to make their demand in a rational manner, in which case the Government would prove not unfriendly. So far no outbreak has been reported, from which we infer that Señor Carranza has observed the Mexican rule that the first duty of the executive is to execute.

GOLD was being won by dredging in the Klondike valley during the coldest weather in January. Our worthy contemporary the *Dawson Weekly News,* in its issue of January 28, makes boast of the fact. And no wonder; it is much to the credit of all concerned, particularly Mr. Joseph W. Boyle, the manager of the dredge in question, known as No. 2 of the Canadian Klondyke Company's fleet. When the alcohol thermometer registered anywhere from 56 to 66 degrees below zero, the No. 2 was in full action, digging vigorously to a depth of 37 feet below the surface, and 32 feet under water. No artificial means is employed to keep the pond warm, the dredge is her own ice-breaker, but her interior is steam-heated. Steam-pipes warm the entire mechanism, maintaining a temperature of 60° F., or 120 degrees warmer than outdoors. The gold production of the Yukon is reported as $4,500,000 in 1915, but if dredging can be conducted throughout the year, we may expect a healthy increase for 1916.

PAPER-MAKING is another industry affected by the War. The production of white paper from wood-pulp involves the use of bleach, or chlorine, of which Germany produces one-third of the world's consumption by the electrolysis of common salt. Bleach was worth $28.50 per ton at New York before the War; it is now selling for more than ten times that price, namely 15 cents per pound. Most of the American supply is made at Niagara Falls, in Michigan, and Pennsylvania. Many new factories have been started to make it, but the supply is insufficient. Much of the chlorine is diverted to the manufacture of explosives; therefore the paper-makers find this chemical increasingly costly and are compelled to raise the price of white paper. Hence our newspapers are becoming yellower and tend increasingly to resemble the Hearst productions. Colors too, owing to the scarcity of dyes, also mainly a German product, are rising in price to the point of being prohibitive. Unbleached wood-pulp has risen from $40 to $58 per ton; bleached pulp from $55 to $100. The export of pulp from Norway and Sweden is subject to embargo, although some of it is allowed to go under restrictions, but in this trade as in others the scarcity of shipping renders the supply precarious. We ourselves have had to pay rising prices for the paper we use. Perhaps our

of this evil some good will arise, for instance, the cost of paper may curtail the fungoid exuberance of the Sunday editions of the daily press, which represent an enormous waste of a useful commodity. The 50, 60, 70, or 80 pages of the Sunday paper consist of 90% rubbish, and enforced thrift in the squandering of pulp and print might serve to discipline the purveyors of piffle.

FROM what we can learn, we infer that Congressional sanction is not likely to be given during this session to the creation of a commission to undertake the systematic revision of the mining law. On the contrary, it is likely that a direct blow at the extra-lateral right will be delivered, by means of Senator Smoot's bill or, more probably, by some legislation emanating from the subcommittee of the House itself. This may result not only in the killing of the extra-lateral right, but in eliminating the requirement of discovery, and in enlarging the claim-area, say, to 1500 feet square. Then the enterprising prospector will plaster the landscape with a succession of claims, to protect the dip of possible veins, which he is no longer required to discover. Thus the abrogation of the much maligned 'apex law' will serve not to promote the search of ore, but to allow of a postponement of such search pending leisurely digging and panning. Frankly, we do not like the outlook. If after all the sincere efforts made by a number of experienced engineers and enlightened lawyers we are to have this half-baked legislation, it would have been better to let the 'apex law' alone.

"SO long Hetty" was one of the mottos inscribed on the banners used to decorate the streets of the mining settlement of Sutter Creek on the occasion of a recent celebration of the re-opening of Hayward's old Eureka mine. Mrs. Hetty Green, an affluent lady residing in New York, had owned this mining property unproductively for many years; in fact, it had lain idle for the time of a generation. We echo the 'So long!' and hope to see other idle owners of valuable mining property advised or compelled to end a policy of dog-in-the-manger, whereby so large a part of the public domain is alienated to no useful purpose. We congratulate the citizens of the little town in Amador county on the resumption of operations at this famous Californian mine and felicitate the community on the fact that the task of re-opening the deeper workings, closed since the fire of 1875, should be in the hands of so experienced a miner and manager as Mr. T. Walter Beam. We shall all watch the disclosure of the bottom levels and stopes with keen interest, not only to see how much of truth there is in the stories about the ore left in the mine but also to observe to what extent the latest methods of mining and milling, conjoined to the lower cost of supplies, will enable the new owners to treat veinstone that was unprofitable forty years ago. It is a fine adventure and we hope it may be rewarded abundantly. Incidentally this re-opening of the old Eureka mine draws attention to the awakening of interest in the Mother Lode region, from Sonora, in Tuolumne, to Plymouth, in Amador county.

Chinese Mining Regulations

Mining in China is the subject of an interesting article in this issue. The author, Mr. A. S. Wheler, knows his subject well. Moreover, he is an engineer of experience in South Africa and elsewhere. While the industry has not been much developed as yet, it is a fact that at the present moment the excited metal markets of the world look to China for a large part of one metallic product, namely, antimony. Even the technology of the subject finds its best exponent in a Chinese metallurgist, Mr. C. Y. Wang. What has been done in a minor branch of mining may yet be accomplished on a larger scale, for the empire-republic dominated just now by His Excellency Yuan Shih-K'ai covers an area of 4¼ million square miles, or a third more than the United States, and includes a number of mineral regions, of which it can be said that they have ore deposits of great variety. In a recent paper on 'Chinese Mining Legislation,' by Mr. William F. Collins, read before the Institution of Mining and Metallurgy, we find it set forth that the Chinese are beginning to realize that foreign mining enterprise is desirable. That idea is not so new as will be the attempt to give it effect. Like many other peoples, the Chinese would like to have the stimulus of foreign enterprise without the alienation of their domestic resources. If the old superstitions and necromancies have become less potent, there still remains a lingering dislike against the interference of the foreign 'devils.' We must look to the educated Chinese, to those who have been to Europe and America as students, and have absorbed the progressive spirit of the age; they are the natural leaders in any friendly effort to join in exploring and exploiting the mineral deposits of the Middle Kingdom. If these men will act in good faith as between their own countrymen and the foreign operator, it will be possible to obtain results satisfactory to all concerned. To be satisfactory any business venture must be mutually profitable. Any other kind of business means imposition on one side. Undoubtedly, the good example set by Russia in encouraging Anglo-American enterprise to exploit Siberia is not without effect, as Mr. Collins suggests. Again, the granting of mining rights to the Japanese in nine districts in Manchuria may be, and ought to be, followed by the ceding of similar privileges to other foreigners, under Chinese regulations, of course. Of such regulations there has been a succession, all of them giving with one hand and taking back with the other, so as to be impracticable when not clearly absurd. For instance, the regulations of 1904 granted sundry rights but required Chinese control of all mining companies and complete subjection to Chinese company law. In 1907, after the foreign ministers at Peking had made numerous representations, a new set of 74 regulations, with 73 supplementary ones, was issued. These also failed to recognize that modern large-scale mining is not performed by individuals, but by combinations in the form of companies. They included a number of impracticable conditions, some of them ludicrous. At about this time Mr. Wallace

Broad was retained as mining advisor to the Chinese. In 1914 a fresh series of rules, multitudinous and detailed, was issued by the Government. We commented upon them in our issue of June 20, 1914, and described them as the work of men unfamiliar both with the practice of mining and the legislation found practicable in other countries. We reverted to the subject in these columns again on April 17, 1915, describing the regulations as having the appearance of being drawn "with the purpose of leading to a maximum of official interference, with opportunities for graft, and a minimum of work." They failed to afford that reasonable opportunity and requisite sense of security without which capital is discouraged from speculative effort. On the other hand, as Mr. Collins points out, the government of the Malay States gives Chinese immigrants every chance to prospect and to mine, the result being that Chinese operators have done well for themselves, and for the tin-mining industry, in the Malay peninsula. The Chinese do not return the compliment. Their regulations disbar the foreign adventurer. We trust that the ministers representing the United States and England at Peking will be moved to another effort to obtain reasonable conditions and in doing so they will find an excellent guide in the eminently fair and sensible summary of the subject presented by Mr. Collins; above all, we urge upon Chinese engineers familiar with mining in this and other countries to use their goodwill in advising their own officials to a more sagacious attitude.

North Star-Empire Compromise

It gives us great pleasure to state that the final negotiations for a settlement of the apex suit between the North Star and Empire mines at Grass Valley have been concluded amicably. As our readers are aware, suit was brought by the North Star Mines Company against its neighbor, the Empire Mines & Investment Company, in June last. Three points of difference had arisen, namely, the right of a junior location to claim extra-lateral rights beneath a senior townsite location, the question as to what extra-lateral rights accrued to a claim having broken end-lines, and finally the geologic continuity of a rich vein uncovered by the bottom workings in both mines. This vein, called 'X' by the North Star and 'Pennsylvania' by the Empire, has been cut on the 63rd level (2500 feet vertically below the surface) in the North Star and on the 46th level (2000 feet deep vertically) in the Empire mine. Sufficient exploratory work has been done in both mines to prove the great value of the ground in dispute, it being conceded that it covers at least $2,000,000 worth of ore. At an early stage it became evident that adjudication of the controversy would involve the decipherment of many intricate problems in structural geology and the settling of several obscure legal technicalities. Fortunately, the good sense of both managements was fortified by the sagacious advice of the attorneys and experts retained by the two companies. The final basis of settlement is an equal division of disputed territory, the different areas being weighted in accordance with the various geological and legal factors pertaining to each. Undoubtedly the experience of the Pennsylvania-W. Y. O. D. case served to warn both parties against proceeding to the arbitrament of the courts, for it had been demonstrated in that case, as in others, that the invoking of the extra-lateral right leads to unsuspected complexities. By the settlement the North Star can stope the disputed vein for 750 feet above the 63rd level, several thousand feet south of the main shaft, for 1000 feet north, and indefinitely in depth south of this limit, while the Empire retains the right to mine on the dip north of the point mentioned, within the major length of the Pennsylvania claim. In short, both mines are given a great extension of life and are saved from the expense, anxiety, and uncertainty arising from a protracted litigation. The credit for this honorable consummation is due to Messrs. Curtis H. Lindley and William E. Colby on the one side and Mr. W. H. Dixon on the other, while among the geological specialists much is owing to Messrs. Fred Searls, Jr., and Ross E. Browne, particularly, if we may say so, to the distinguished veteran. Of course, no man can foresee what is contained in the areas apportioned to the two companies; at best, each receives a pig in a poke, but they are taking equal chances and making an equally sagacious compromise with chance. Each becomes assured of a fair share of profit from the disputed territory, instead of running the risk of losing the whole of that share. The example set by them is one that we hope will be followed by other adjoining proprietaries, for we feel assured that it is to the benefit of the mining industry.

The Psychology of Flotation

Any attempt to understand the scanty and contradictory literature of the flotation process is bound to be unsuccessful without the help of some knowledge of those personal equations that have rendered the subject so perplexing to the later student. Credit, for example, was begrudged to the Elmore brothers for their early work at the Glasdir mine, in Wales, in 1898, because it was known that they had carried forward experiments previously started by the late George Robson, in 1894, but it is a fact that Robson devised no workable process, while the Elmores did. Again, the latter placed their Australian rights under option in 1902 to Messrs. John Ballot and W. W. Webster, by whom Messrs. H. L. Sulman and H. F. K. Picard were employed as metallurgists. The option was not exercised, the group that declined it organized the Minerals Separation company and proceeded to exploit a method of their own. Whereupon, not unnaturally, there were heart-burnings and ill-feelings, culminating in the lawsuit of 1907, which decided nothing, but left a lot of acid in the freely flowing pulp of competition. Later came the litigations and rivalries of the various processes in Australia, leading to many queer doings, such as the surreptitious addition of oil to operations in which it was not supposed to be

present, and the dropping of scrap iron into the agitators and sumps of the mill just to prove that the process in use was not as good as the other fellow's. Real progress was made by Minerals Separation when that company engaged Mr. T. J. Hoover as its general manager in 1906, but regrettable misunderstandings ensued when he resigned in 1910. The publication of his book on flotation, two years later, increased the surface tension. Shortly afterward, Mr. J. M. Hyde, who had been in the employ of Minerals Separation for one year, also resigned and proceeded to Montana, where he erected a flotation plant at the Butte & Superior mine during 1911, in disregard of the Minerals Separation patents. This led to the first important American suit for alleged infringement and at the same time marked the beginning of a revolution in the wet metallurgy of the base metals in the United States. Again the irony of fate came into play when, in 1914, Mr. J. M. Callow patented and introduced the pneumatic cell, with its porous bottom, the idea of which, unknown to him, had been patented for Minerals Separation by Mr. Hoover in England in 1910. This device for frothing was adopted by the Miami Copper Company in 1914 and provoked the second important litigation, it being claimed by the Minerals Separation company that the process at Miami is an infringement on certain of their patents, while the users of the Callow cell assert that it involves a procedure and a process radically different from the ordinary frothing method by mechanical agitation. Attempts were made to obviate litigation, but a lack of concession prevented a compromise. The royalties asked are not particularly excessive, but the forms of contract provoke natural resentment. The Miami opposition represents not that company alone, but a large group of copper enterprises, notably those directed by Mr. D. C. Jackling and his associates.

No application of the bubble-levitation phase of flotation to the concentration of ore was made in the United States until long after the Minerals Separation basic patent was registered. The patent was obtained in 1905, but the first introduction of the process was not made until 1912. Over six years elapsed. Yet it is claimed by Minerals Separation that "if the directions of the patent are followed, the operation of the process is inevitable." Many years of trial and experimentation were required before flotation became a practicable process in this country. It is claimed that the Jackling companies made successful application of the process by aid of their own research and persistent effort. Moreover, it is a notable fact that up to 1911 the Minerals Separation metallurgists thought chalcocite could not be treated by flotation, and said so. In Mr. Hyde's report of January 8, 1911, given as an exhibit by Minerals Separation in their suit against Hyde, it is stated that the tests made in the company's London laboratory proved that "the copper ores of a good part of the South-west and also of at least a portion of the Utah region contain chalcocite, which is not floatable by any of the methods so far tested." This opinion epitomizes the experience gained up to that time in the London laboratory of the Minerals Separation company. Even in the 1914 edition of his book, 'Concentrating Ores by Flotation,' Mr. Hoover mentions the presence of bornite and chalcocite as likely to limit the successful operation of the process. It is evident, therefore, that the patentees did not bring any metallurgical revelation to those exploiting the big deposits of disseminated copper in Utah, Nevada, Arizona, and New Mexico. We know now that chalcocite is easier to float than pyrite, and on this fact an enormous metallurgical development is based. It is fair to add that at a later date the representatives of Minerals Separation learned that chalcocite was amenable and prevailed upon the Anaconda and Inspiration managements to try the process, to the gain of all concerned. Who first demonstrated that chalcocite can be concentrated by froth, we do not know. Whoever he was, he deserves grateful remembrance.

Another factor tending to confuse the understanding of the relative values of the various patents is worthy of mention. Experiments in court, and elsewhere, have been used to prove that this or that patent will produce certain effects when the description of the patent is followed. As a matter of fact the result of the experiment depends largely upon the manipulation, performed usually by an operator who knows a great deal not disclosed at the time the patent-description was written. Moreover, the improvement in apparatus facilitates the obtaining of results not contemplated by the followers of the prior art. In short, by aid of Herodotus and a slide machine the expert in a court-room can produce performances that will perplex a philosopher, and a judge. Thus undoubtedly the dexterity of clever technicians and the animus against Minerals Separation have combined to glorify the Everson patent and to credit the lady in Colorado with the discovery of a workable process. In the same manner, the instructions of Aleide Froment have been misapplied in such a way as to rob his contribution to the subject of its true significance. To us Froment appears as the connecting link, psychological if not metallurgical, between the Elmore brothers and Messrs. Sulman and Picard.

Another problem is presented by the claims to originality made after the event, when the importance of priority has sharpened the imagination. Much of the misunderstanding of facts is quite unintentional and is therefore most difficult to distinguish from calculated misrepresentation. Prejudice has raised a fog through which it is difficult to see. We sympathize with the judges, having read much of the testimony submitted to them. Indeed, the technology of flotation has suffered greatly from the fact that the litigation has dominated it almost from the first. This has been supplemented by personal vendettas and factional fights of a bitter kind causing many to see red rather than to see straight. In consequence, the literature of the subject is deeply vitiated by the distortion of scientific vision, rendering it most difficult for the student to extract the essential truth.

The Flotation Process—I: Physics

By T. A. Rickard

*IN a recent reminiscence my friend Ben Stanley Revett has recorded[1] how he bet "a bottle of bubbles" with that peripatetic philosopher Thomas F. Criley, the partner of Carrie Jane Everson in an oil process of concentration whereby the valuable sulphides were made to float above the worthless gangue in a pulp of crushed ore. Mr. Revett says that he bet his bubbles against Criley's, but we suspect that in saying so he was interpreting the prior art in terms of latter-day metallurgy, for it is doubtful whether any of the persons concerned in that early experiment at Baker City, Oregon, had a clear understanding of the function of the bubbles in assisting the oil to give buoyancy to the sulphides. However, in staking his bubbles of carbon dioxide dissolved under pressure in the vintage of Champagne against the performance predicated by Criley, Mr. Revett must be credited with successful anticipation, for 27 years after the incident we know that the key to the flotation process is to be found not in the oil, the acid, or the apparatus, but in the bubbles.

The man who understands the physics of a soap bubble has mastered the chief mystery of flotation. The small boy, who, as pictured by Millais, watches the birth, ascent, and bursting of the iridescent sphere of his own making, is the type of our modern metallurgist who makes the multitudinous bubbles constituting a froth and then wonders to what laws of physics this filmy product owes its existence.

To put it briefly, the boy, having dissolved soap in water, holds a little of it in the bowl of his clay pipe while he blows through the stem. The soapy water forms a film that is distended by the boy's warm breath into a lovely sphere, which is lighter than the surrounding air and therefore rises, while the sunshine undergoes refraction into the colors of the spectrum. When the boy blows through his pipe into pure water, he makes bubbles likewise, but they break instantly. It is the soap that lengthens their life. In the language of physics we say that high 'surface tension' causes the pure-water bubbles to burst immediately, while the addition of soap introduces a contaminant that lowers the tension so as to enable the bubbles to last longer.

The basic factor in the making of bubbles is surface tension. This is the force that causes the surface of a liquid to resist rupture. The particles at the surface have a greater coherence than the similar particles within the body of the liquid. In other words, each molecule within the interior of the liquid may be pictured as surrounded by molecules like itself in being attracted toward each other equally in all directions; while the molecules at the free surface of the liquid are attracted only by those internal to themselves, the result being to constrict the free surface to the least area. In consequence, the surface acts as if it were elastic. Hence the attachment of water to the sides of a tube and the drawing of that water upward—which is called 'capillarity' because it is most marked in a tube as small as *capillus*, a hair.

Numerous manifestations of surface tension on water could be cited. Fill a tumbler a little more than full and the water will have a convex surface, indicating that there is some force at work to prevent the water from spilling. Note the cohesion between two plates that have been wetted. Dip a camel's hair brush into water and the hairs cling together; immerse the wet brush in the water and the hairs separate. Watch the formation of a drop of water and note that it behaves as if enveloped by a stretched membrane. Water-spiders can be seen running over the surface of a pond in summer, as small boys run over a pond covered with ice in winter. The ice bends under their weight without breaking; so also the spider[2] makes a visible dimple without wetting his feet. The surface is not ruptured.

The force of surface tension has been measured by ascertaining the weight that can be suspended from a film of water in air.[3] It has been stated as 3¼ grains per inch[4] or 81 dynes per centimetre.[5]. The most recent determination is that of Theodore W. Richards and Leslie B. Coombs,[6] who found it to be 72.62 dynes per centimetre at 20°C. Many disturbing factors enter into the measurement of this force, so that divers figures, ranging from 70.6 to 81, have been announced at different times.

Surface tension differs as between various liquids and fluids in contact; for example, the tension separating mercury from water amounts to 418 dynes per centimetre, while that separating olive oil from air is only 36.9 dynes. A drop of pure water will spread over the surface of pure mercury as oil will spread over water. The surface tension of an oil-water surface is only 14, as compared with the 73 of an air-water surface at a temperature of 18°C.[7] While the film of oil on water

may be only one molecule thick, or one twenty five millionth of an inch, it will suffice to reduce the effective pull of the water surface from 73 to 43. This latter figure represents the effective surface tension of water modified by oil as used in flotation. It is the main factor in the formation and persistence of a bubble. Heat lowers the surface tension of water. Place powdered sulphur on the surface of the water on a horizontal plate of clean metal; apply heat locally; the sulphur is pulled away by the cold liquid as against the feebler tension of the warmer liquid.

This elastic force at the surface of a liquid tends to draw it into the most compact form. That is why a drop assumes the form of a sphere, in which shape it presents the smallest surface in relation to its volume. Surface tension is a contractile force. This is shown in

Fig. 1.

a simple way by blowing a soap bubble on the large end of a pipe and then holding the other end of the pipe to a candle, when the air escaping from the shrinking bag of the bubble extinguishes the flame, as in Fig. 1.[8] When water is spilled on a stove, it assumes a globular form and dances on the hot iron until it flashes into steam. When water is sprinkled on a dusty floor, the dust forms a layer upon the drop of water, which draws itself together into rolling spherules. The smallest drops are the most nearly round; in the larger ones the weight causes a flattening, because gravity overcomes the elasticity of the surface film. That is shown even more clearly in the case of drops of mercury, and by the beads of gold on an assayer's cupel.

This contractile force at the surface, whereby a portion of liquid gathers itself together into spherical form, explains why the pure-water bubble bursts so readily. The high tension shatters it. It does not burst explosively, by expansion of the gas within the envelope, but by lateral displacement of the substance of the elastic film. It collapses because the surface tension draws it together. To prevent such immediate collapse it is necessary to lessen the tension, that is, diminish the contractile force in the elastic membrane constituting the film of the bubble. This can be done by introducing an impurity or contaminant, which lowers the surface tension, that is, diminishes the contractibility of the bubble-film. Water has the highest surface tension of any common liquid except mercury, so that the addition of another liquid usually lowers its surface tension.

Oil in emulsion and organic substances in solution can be used for this purpose. Soap will have the same effect, and that is why a soap bubble lasts longer than a pure-water bubble, the film of the former consisting of water having some soap in solution. When water has been modified by such a contaminant, the components of the film can so dispose themselves that the superficial forces will be the same everywhere, that is, tend to remain in equilibrium, including the force of gravity, which otherwise would pull the film apart.

When two bubbles come in contact they tend to coalesce because the two of them have an aggregate area greater than that required to include the same amount of air within a single bubble. In pure water the bubbles coalesce with a violence that is mutually destructive. Even when a survivor is left, the violence of coalescence of such bubbles in a pulp unhorses any mineral particles that may be riding the bubbles. When, however, the water is modified by oil, the contractile force of surface tension is diminished, the bubbles are less fragile, and they survive long enough to perform their metallurgical duty of buoying the metallic particles to the surface of the liquid pulp. In practice the 'modification' of the water is effected by emulsification or minute subdivision (as in a mayonnaise) of an insoluble oil, such as cotton-seed and oleic; or it may be done by means of a soluble oil or derivative, such as cresol and amyl acetate.

The presence of a contaminant in water may also affect its viscosity or internal friction, whereby it offers resistance to a change of shape. This strengthens the film of a bubble generated in such water. Moreover, it has been asserted[9] that a concentration of the contaminant occurs in the surface of a liquid, causing the viscosity to be highly magnified as compared with the body of the liquid. It is also known that the films made of any definite liquid are of the same strength, irrespective of their thinness; so that the attenuation of the skin of a bubble does not decrease its strength. This again follows from one of the most remarkable properties of a bubble: the ability, within small limits, of adjusting its tension to the load.[10] Briefly, the tension at the surface of a contaminated liquid is able to adjust itself within fairly wide limits. Thus a film of such a liquid can remain in equilibrium when a film of pure liquid[11] would have to break.

[8]C. V. Boys in 'Soap Bubbles,' page 49.

[9]Samuel S. Sadtler in Minerals Separation *v.* Miami case.

[10]'Thermodynamics,' by Willard Gibbs. Page 313. "In a thick film, the increase of tension with the extension, which is necessary for its stability with respect to extension, is connected with an excess of soap (or some one of its components) at the surface as compared with the interior of the film."

[11]In a chemically pure liquid it is impossible to form froth or multiple bubbling. Some differentiation of the components of a liquid is required to make a film.

In his book T. J. Hoover[12] states how the presence of a mere trace of saponine will kill the froth in the flotation cell. He does not explain why. It happens that saponine, which can be dissolved out of horse-chestnuts, is an aid to the blowing of big bubbles. But they are weak and tender. Why? Because saponine *increases* the tension.[13] When a saponine bubble is brought into contact with a soap bubble, the former contracts and blows air into the soap bubble. Rayleigh proved that the tension of the soap-film is only two-thirds of that blown from a saponine solution of equal strength. One part of saponine in 100,000 parts of water will suffice to make a liberal froth. But the bubbles are flimsy. They are so fragile as to render them of no use as carriers of mineral. Hence they spoil the normal working of a flotation-cell, in which it is necessary to employ a contaminant that lowers the surface tension so as to yield bubbles that are both persistent and sufficiently robust to buoy mineral particles.

In approaching the rationale of the process under discussion it may now be assumed that we are dealing with a pulp consisting of ore and water, modified by oil, the ore having been crushed sufficiently to separate the metallic sulphides from the associated gangue in a pulp consisting of minute particles of each. In ordinary water-concentration the lower specific gravity of the gangue permits the mill-man to wash it away from the heavier metallic sulphides, but in the flotation process this action is reversed, the metallic particles being lifted above, and away from the gangue particles. Apparently, it is a metallurgic anomaly.[14]

To this crushed ore we have added oil. The oil serves as a contaminant that lowers the surface tension; also it augments the viscosity of the liquid. These two effects unite in facilitating the formation of strong and persistent bubbles. The necessary air is introduced by agitation or by direct injection. Sea-weed contaminates sea-water and makes foam in the breakers, as oil makes froth in fresh water that is agitated.

Air has a marked adhesiveness for metallic surfaces: this attachment is supposed to be enhanced by the presence of oil or grease on the metallic surface. In other words, the metallic surface, such as that of a sulphide mineral, when in the presence of both oil and water, will exhibit a preference for the oil. Hence the sulphide is not wetted. This characteristic is less marked on the part of the heavy silicates, such as rhodonite or garnet, and still less evident in the case of the lighter silicious minerals, such as quartz and orthoclase.[15] The addition of acid lessens the oil attachment to the gangue particles without decreasing the selectiveness of the oil and the air for the sulphide particles. Thus we can understand why the bubbles attach themselves to the metallic particles and buoy them to the top, while ignoring the gangue particles, which sink to the bottom of the vessel in which the pulp is undergoing stirring or agitation. This preference of air for metals and metallic surfaces must be emphasized. It is the decisive factor in the process of flotation. Most minerals when pulverized, and then sprinkled on water, will float, particularly if they are in flakes or plates, as gold often is and as minerals with a highly developed cleavage usually are. Such flotation is due to air, which forms a discontinuous film under the mineral particles. Mickle proved this by taking a magnetic mineral, like pyrrhotite, and pulling it out of the water by a magnet, when it could be seen that the water was dragged up with the mineral. These minerals float for the same reason as an ungreased needle will float, namely, the resistance to rupture of the surface of the water and the aid of the air attached. It used to be supposed that the needle must be greased in order that it may float. That idea, like the general exaggeration of oil as a factor in flotation, has been disproved by experiment.

If, to water in which mineral dust is floating, an addition of alcohol or caustic soda be made, or even the vapor of alcohol be allowed to play on the surface of the water, the mineral particles will sink.[16] The contamination of the water has decreased its surface tension.

The bubbles collect the metallic particles, that is agreed; but whether the selection is dependent upon the previous oiling is a disputed point. Apparently the adhesiveness of air for metallic surfaces is greater than that of oil, and it would appear probable that in the flotation process the first phenomenon suffices without the aid of the second. It used to be an accepted canon of flotation that the oil coated the metallic particles, which therefore were not 'wetted' and did not sink, while the gangue particles were not oiled and therefore were wetted, especially in acidulated water, so that they sank. Testimony has been given by a keen observer that "the distribution of the oil in the concentrate and the gangue is entirely fortuitous."[17] It is even asserted now that instead of the oil residing with the metallic particles exclusively, and leaving the gangue untouched, it is distributed throughout the mixture. When the larger proportions of oil were employed, it is likely that such promiscuous oiling of all the particles of the pulp did take place, but now that the quantity has been reduced to a proportion so small that the presence of oil on the concentrate is not discernible by the senses, we may assume a preference for the metallic particles in accordance with laboratory observation. This appears to be confirmed by experiments showing that in the case of specific minerals, such as chalcocite, it is necessary to

[17]Bertram Blount, testifying for Minerals Separation in the Elmore appeal before the Privy Council. I might add that 'fortuitous' is a word that describes other things in the history of flotation besides the oiling.

oil the mineral in order to lift it by an air bubble.[18]

When using the, at present, minimum quantity of oil—say, one-third of a pound per ton of ore—it would appear that the oil forms a coating of microscopic thinness upon the metallic particles. The minimum thickness is the thickness of a molecule.[19]

Metallic surfaces have a selective adhesion for air and for oil, as we have seen. Therefore the molecular forces of the oil and of the metallic surfaces may be supposed to unite in attracting the bubbles. What the nature of those forces may be is yet a matter of conjecture, although the idea that they are electro-static is suggested by the fact, among others, that the metallic sulphides most amenable to flotation are good conductors of electricity.[20]

The foregoing statement of physical principles applies more particularly to the frothing method. The history of the 'prior art,' as it is called in patent litigation, shows that the first stage of the flotation process as now in vogue was performed by the use of a large proportion of thick oil. This is typified by the bulk-oil method of the Elmore brothers. It depends upon the lower specific gravity of oil as compared with water, so that when mixed in a pulp of crushed ore the oil rises to the top, dragging the metallic sulphides with it. This also was explained formerly as due mainly to the selective adhesiveness of oil for metallic surfaces, which prevents them from being wetted, while the lack of a similar affinity on the part of the gangue particles enables them to be so wetted as to cause them to sink to the bottom. All of this is measurably true, but the underlying fact seems to be that an excess of viscous oil causes the oiled particles to adhere or stick together so that they are rafted to the top. It is probable that when thus collected in groups they are more readily floated on account of their ability to hold more oil, as compared with individual particles, because the oil fills the spaces between the members of a group.

The lighter oils have a specific gravity ranging from 0.8 to 0.95, as compared with the 1.0 of water, so that the margin for flotation is small. For instance, in the case of a mixture of an oil having a specific gravity of 0.9 and of zinc-blende, having a specific gravity of 4, it is necessary to use 6.7 parts by weight of oil to one part by weight of blende in order that the mixture may have a specific gravity equal to that of water. Thus an ore containing 20% blende, or 400 lb. per ton, would require the use of over 2680 lb. of oil in order to float all the blende in the ore.

In true bulk-oil flotation, which, as a matter of fact, was rarely performed, the phenomenon of surface tension does not play a prominent part. It is mainly a question of raising a mineral heavier than water by aid of a liquid lighter than, and not soluble in, water. The emulsification of the oil was carefully avoided by Elmore. In the later phases of flotation, in which the proportion of oil becomes steadily less, it is aimed to emulsify the oil and air. The oil produces a 'micro-emulsion of air,' as Leverrier expressed it. Thus the air is thoroughly distributed in the pulp and the oil is brought into intimate mixture with the water, which is thereby modified and prepared for the making of persistent bubbles.

HEATED CYANIDE SOLUTIONS are of considerable benefit on the silver ores of Tonopah and other places, but E. A. Wraight, in a paper read before the Institution of Mining and Metallurgy, came to the following conclusions: (1) The effect of heating cyanide solutions is of very doubtful benefit; the extraction may be increased for a short period, but this is more than compensated by the increased cyanide consumption and the subsequent decrease in the rate of dissolution of gold. (2) Oxidizing agents (H_2O_2 excepted) are apparently of no value, and may even exercise a deleterious effect on the extraction. (3) The addition of oxygen in a more active form, either as hydrogen peroxide or by means of heated air, increases the solvent activity of cyanide solutions in a very pronounced manner. The author stated that his experiments were by no means complete, and that considerably more work is needed before the results can be established as absolutely definite. The work, however, occupied a considerable length of time, as all the apparatus had to be made and fitted together before any work was possible, and several breakdowns and failures were experienced. The results are submitted to the Institution in the hope that if the matter proves of sufficient interest others who may have the opportunity will carry on these investigations. The effect of different temperatures of the air-blast, the comparative times required by hot and cold air agitation to effect, say, a 98% extraction, the possibilities resulting from the use of ozone, are matters which might be investigated with profit. The results obtained by the author undeniably point to the probability of a better extraction, and in any case to the certainty of a more rapid extraction by the employment of heated air. The advantage of this is apparent when economy of space or plant is a matter for shareholders' consideration, and in conclusion it may be pointed out that the expense of testing the air is merely nominal, and the waste heat from boilers, etc., would readily lend itself to this purpose. In his paper the author does not mention the results at Tonopah, nor the notes published from there, as have appeared in the PRESS from time to time. In the cyanide plants of this silver-producing centre, heated solutions are of considerable benefit. Both live and exhaust steam are used for the purpose. At the mortar-boxes the temperature is from 60 to 70° F., this being increased up to 120° in the agitators, the pulp being warm throughout its treatment. Extraction is increased by 2%. The cost of heating may be as high as 30c. per ton, but the better recovery pays for this.

Metalliferous Mines of Hunan

By A. S. Wheler

INTRODUCTION. *The province of Hunan in China is endowed with a variety of mineral deposits. With the exception of the Shui-ko-shan property, the mines are practically all worked in primitive Chinese fashion which has been practised without material alteration for centuries. A Chinese mine may be described as a ragged hole in the ground off which numerous irregular excavations have been made, following the ore and working it out wherever found in sufficient quantity.

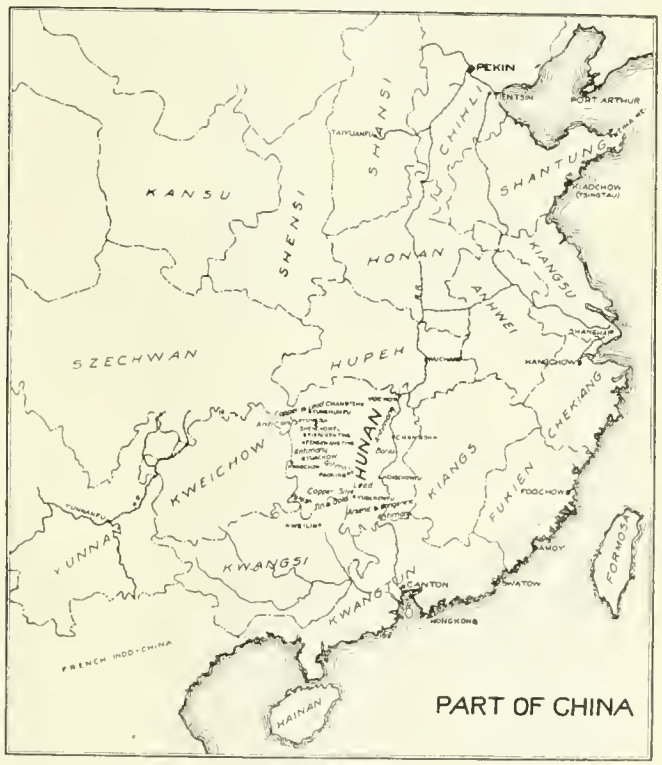
The result is a sort of bewildering rabbit-warren of workings, usually none too safe, up and down which one clambers on ladders and timbers affording a slippery and precarious footing or grasp. Development work is rarely undertaken, so that there is no reserve of ore to tide over a rainy day; hence when a poor zone is encountered the mine has to be closed-down for lack of funds. Practically all work is done on contract, whether mining, hoisting, pumping, or ore treatment. The method of working and the control and direction of the operations is left entirely to the workmen; it is extremely rare to find a manager who will venture underground or who has the knowledge and experience to enable him to assume technical control. The mining is let to one or more underground contractors and paid for at so much per picul of picked ore; they engage the miners, providing them with the necessary tools and explosives. For the latter purpose native-made black powder is used, the fuse being of straw and touch-paper with powder filling. For illumination, flare-lamps are employed; these consist of a shallow iron saucer suspended at the end of an iron rod and filled with vegetal oil in which are immersed wicks made of wood-pith. As ventilation is allowed to take care of itself, the underground atmosphere resulting from the fumes of the explosive, and the smoke of the lamps, can be better imagined than described.

The pumps are quite ingenious. They are made of bamboos 5 inches in diameter from which the inside rings have been cut, thus forming the pump-barrel. The rod is a long strip of bamboo to the end of which is fixed a disc of hide of the same diameter as the bore of the bamboo. This acts as a flap-valve and is seated or supported on a smaller disc of wood. A cross-piece fixed to the other end of the strip serves as a handle. The coolie actuates the plunger, and the discharge end of the bamboo delivers the water into a small cistern or sump on which he sits. The suction of a similar pump above him draws from this cistern and raises the water to the one next above, and so on. The method is crude but it answers admirably for comparatively shallow workings, as labor is cheap and the capital outlay a minimum.

*Abstract from *The Far Eastern Review*.

The broken ore is usually picked over roughly underground to eliminate waste and is carried or dragged out of the mine in basket-loads of 80 lb. weight or more. In the narrow tortuous workings of the average Chinese mine this work is extremely arduous. The ore is then cobbed and sorted before being subjected to treatment for its valuable content.

ANTIMONY. This is by far the most important mineral product of the province: in fact, China is the world's chief producer of antimony and the bulk of the output comes from Hunan. It is marketed in various forms.



Antimony regulus is the metal and the production of it is the monopoly of the Hua Chang Company, granted under the Manchu régime and recently extended by presidential mandate. The Hua Chang Company owns the French patent rights for China of the Herrenschmidt furnace, which is especially adapted for the treatment of low-grade sulphide ore. The process consists in mixing the broken ore with charcoal and heating with regulated admission of air. The sulphide is thereby converted into oxide, which is volatile and is drawn off and condensed in special chambers. The oxide is then mixed with suitable fluxes and smelted in the ordinary reverberatory furnace. The molten metal is ladled into molds and allowed to cool slowly and undisturbed beneath a covering of slag. This produces the fern-like markings on the surface of the ingot which is held to be a sign of

freedom from impurities, but as a matter of fact is not necessarily so. Chinese regulus, however, compares favorably with any on the market and runs over 99.5% metal.

Antimony crude is the most usual form in which antimony is marketed in China. This consists of concentrated antimony sulphide, which is obtained by the process known as liquation. The ore, in small lumps or dust, is heated in a clay crucible or pot. The sulphide, being easily fusible, melts and percolates through a hole into a lower pot, whence it is ladled into molds. Crude contains roughly 70% of antimony metal. Another form is ash, which is the residue from liquation. This may run as high as 30% or more of antimony. It was formerly regarded as waste but is now being roasted and smelted locally for the production of regulus. Antimony ore is shipped to Europe for treatment, and works have also been recently established at Hankow for the production of crude and regulus. It must be mentioned that Hunan ores are remarkably free from deleterious impurities such as lead, copper, arsenic, zinc, etc. The export figures from Changsha for 1914 are

	Tons.
Regulus	3,955
Crude	13,792
Ore	8,859
Ash	2,150

Owing to the largely increased demand for the metal, which is used in the manufacture of munitions of war, and to the fact that other producing centres, such as Mexico and France, are not in a position to maintain their output, prices have soared to the highest level yet reached.

Antimony ore is known to occur at numerous points, but the principal mines are situated in central Hunan. By far the most important field is Hsi-keng-shan, which lies 21½ miles east of Sinhua, on the Tzu river. The prevailing geological formation is dolomitic limestone. An abrupt scarp marks the line of the lode, which is over a mile in length and honeycombed with the workings of 70 companies or owners. The ore is stibnite partly oxidized above the water-level. It occurs in the form of seams, pockets, and masses generously distributed throughout a layer of limestone varying in thickness up to 40 feet.

The ore is sorted underground, carried to the surface, cobbed, to remove adhering waste, and sorted closely. The picked ore runs as high as 65% antimony, and the lower grades about 40%. The fine ore and dust is concentrated by hand-jigging in baskets. Owing to the high prices now ruling all the old waste-heaps are being carefully sorted and the ore concentrated by cobbing, crushing, and jigging. There are seven local smelting works in which the bulk of the ore is converted into crude. The oxide was being smelted to regulus in reverberatory furnaces, but this is believed to have been stopped by the monopoly-holders. The district produces 1000 tons or more of crude per month, and it is estimated that fully 10,000 persons are directly employed.

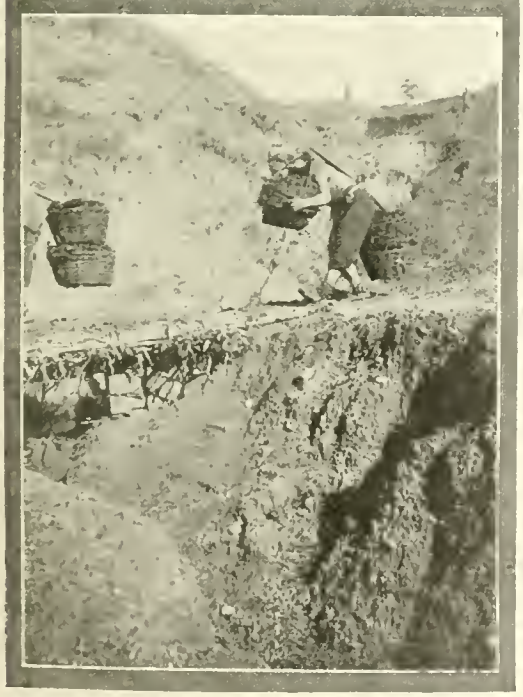
The Panhsi mines are situated 25 miles south of Chanhsi, a small town on the Tzu river 36 miles above Yiyang. The surrounding country is mountainous and composed of sedimentary strata tilted and bent by granitic intrusion, but not much altered. Four mines are being worked. The orebodies are of the fissure-vein type, the ore occurring in shoots. These have been worked to depths varying from 150 to 500 ft. measured on the dip, which ranges from 70° to vertical. The vein-filling is quartz or interlaminated schist and quartz, and the stibnite usually occurs as a narrow seam hugging the footwall. The average width of the veins probably does not exceed 15 inches, though very occasionally they swell out to five feet.

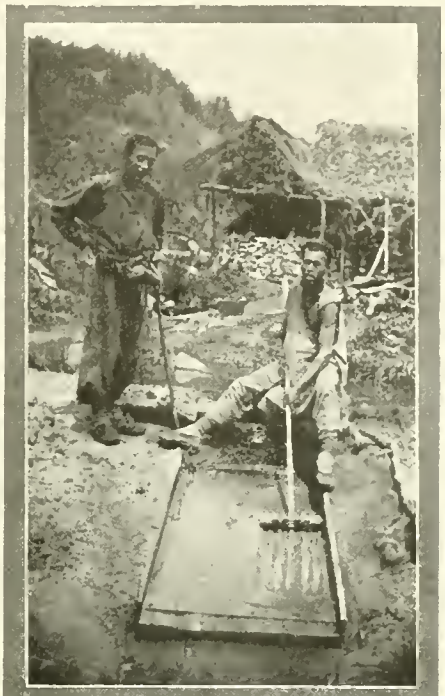
There is no dressing or smelting plant; the ore is cobbed and sorted to 30% grade and 400 tons is shipped monthly to the Hua Chang works at Changsha. From the mine it is carried 2½ miles and then rafted down a small stream on bamboo rafts, each carrying half a ton to a point on the Tzu river, where it is transshipped into junks carrying 8 or 10 tons each. This ore supplies the Herrenschmidt furnaces and is converted into regulus, as previously described. Other mines of less importance are Wu-hsi in Shenchowfu, Hua-pan-hsi in Anhuahsien, and Chiang-hsi-lung in Chüpu-hsien. These are geologically similar to the Panhsi mines, the ore being, however, of higher grade. The output from these is less than 100 tons per month; and there are numerous other smaller producers in various parts of the province.

Lead and Zinc. The vast slag-heaps found at Kwei-yang-chow and south-east of Chenchow testify to the existence of a considerable industry in the smelting of argentiferous lead ore in past times, and pieces of galena recovered from ancient workings have assayed high in silver. This industry is practically extinct, but there are still a few small mines producing lead and zinc ore and by-products from associated minerals. The only one of any importance, however, is the Shui-ko-shan, controlled by the Hunan Official Mining Board. This property, as already mentioned, is run on foreign lines, and is probably the largest of its kind in China. It is well situated as regards transport and accessibility, and can be approached either overland from Hengchow, from which town it lies 32 miles distant in a southerly direction, or up the Siang river to Sungpo, the loading-station, just above the confluence of the Kwei and the Siang. From Sungpo a light railway 3 miles long connects with the property.

An examination of the geological structure shows that the ore-carrier is limestone covered to the north and west by slightly unconformable red sandstone and shale. An intrusion of syenite has tilted these into the form of an anticline, the crest of which has since been denuded. The ore deposit consists of large irregular bodies of mixed galena, zinc-blende, and iron and copper pyrites, which have been formed at or near the contact of the syenite and the limestone, as a result of this intrusion. Official records, covering the past 20 years, show that the mine has produced during this period over 50,000 tons of lead concentrate and over 126,000 tons of zinc concentrate, but there were extensive native workings prior to 1896, prob-

ably dating back for centuries. A portion of the mine is still worked in native fashion, but the main workings consist of an incline-shaft, sunk to a depth of over 600 ft., from which four levels have been driven, and of a small vertical shaft 160 ft. deep below this point serving the fifth and sixth levels. The ore is sorted underground and then cobbed and sorted again at surface. This yields clean high-grade lead and zinc ore, ready for shipment. The balance is a mixed product of varying size. The lumps are partly stacked as a reserve at surface and the remainder together with the coarse goes to the foreign plant for treatment. The dust and small pieces are sent to the Chinese dressing-floors.





In the foreign plant, the ore is first crushed and sized and then fed to mechanical jigs and Wilfley tables which produce a lead concentrate, a zinc concentrate, and intermediate products; the latter are at present being stored for future treatment. The Chinese process consists of repeated hand-jigging in baskets, which yields lead and zinc concentrates and a mixture. The latter is treated by washing down an inclined plane several times, whereby lead concentrate is separated out, the balance going to waste. The capacity of the foreign plant is about 50 tons per day and of the Chinese plant rather less. A new foreign plant with a capacity of 100 tons per day is in course of erection. During 1914, a total of nearly 56,000 tons of ore was treated yielding 5000 tons of lead concentrate and 14,600 tons of zinc concentrate. These respective products are stated to average 70% of lead with about 8% zinc, 30 to 40 oz. silver per ton, and over 30% zinc with 5% to 10% lead impurity. The cost of producing a ton of concentrate is about $13, local currency, excluding depreciation, amortization, etc. The concentrates are sold under contract to Messrs. Carlowitz & Co., of Hankow, who re-treat them in their works at Wu-chang, whence they are shipped to Europe to be smelted. An experimental lead and zinc smelting plant using native methods has been established by the Hunan Board near Sungpo, where both these metals and also silver are being produced.

Tin. The tin districts of Hunan are situated in the most southerly portion of the province close to the Kwantung border. The An-yuan mines in the Ichang district show the largest output at present. A deposit of quite exceptional nature is being worked here, and is of a type which, so far as the writer is aware, is known at only

three or four places in the world. The formation is limestone tilted and metamorphosed by a granite mass. A dike of granite, probably of more recent date than the main mass, has penetrated the limestone and along the course of this are found true chimneys or pipes of tin ore, associated with arsenical pyrite, actinolite, and a little copper pyrite and fluorspar. The pipes are roughly circular or oblong in cross-section, varying from 20 ft. downward in diameter. The maximum depth reached is 400 ft. and the dip of the pipes ranges from horizontal to vertical.

The mineral contents are arranged in concentric rings or layers, usually sharply defined, and slightly oxidized on the outer edge, the interior being sulphide ore. One pipe is a marked exception to this, for it is oxidized to a soft red earth and clay to a depth of 300 ft. The dressing of the ore consists of cobbing and sorting, the clean arsenical ore being stacked for separate treatment. The remainder is then roasted, the arsenious oxide ('arsenical soot' of commerce) being collected by condensation in dome-shaped chambers built of rough stone and plastered with clay inside. This soot is placed in thin iron basins over a fire, covered with a similar basin inverted, and subjected to a prolonged second heating, when the arsenious oxide is deposited as a 'glass' on the upper basin. It is sold in this form for agricultural purposes. The roasted ore is then crushed by water-driven Chinese stamps, after which it undergoes a series of concentrations.

The first of these is affected by raking the ore over from side to side in a shallow stone-paved pit into which water is flowing. The 'heads' from this operation are further concentrated by repeated washings down a concave incline. The concentrate is then mixed with loam and re-roasted to drive off the associated arsenic; after it undergoes a second crushing and concentration, as above described. The smelting is conducted in a cylindrical furnace built of brick or stone bound with clay. Blast is supplied by a double-acting Chinese bellows through a two-inch opening pointing downward from the back of the furnace. The furnace-door is stopped with clay and a layer of live charcoal is placed on the furnace-bottom and blown up to a good heat. About 70 lb. of concentrate mixed to a thick paste with 'incense-wood' pulp is then charged and covered with a layer of charcoal. The smelt lasts for 24 hours, charge and fuel being added half-hourly, and the blast continued throughout. Shortly after starting an iron rod is inserted in the furnace-door and through this tap-hole the molten tin trickles out slowly into a clay-lined depression where it is kept covered with live charcoal. When sufficient has collected, it is ladled into sand molds forming ingots of about 50 lb. each. The metal thus obtained runs over 99% tin.

The Hsiang-hua-ling mines are situated in the Linwu-hsien 18 miles north of Linwu, in wild, mountainous country. Five companies are at work here, of which the Hunan Official Mining Board is the most important. The geological structure shows that the mineralization is due to a granitic intrusion between quartzite and a conformably overlying highly fossiliferous limestone. This has produced a displacement and fissuring of the latter, with however but little alteration. The fissures are numerous but apparently of short lateral extent, though well defined. An intersection is usually marked by a good patch of ore. The associated minerals are arsenic, iron, and copper sulphides; with occasional bunches of fluor-spar in big cubic crystals. The processes of ore-dressing and smelting are precisely the same as at the Anyuan mines. A local custom, prevalent in both fields, is to reckon a picul of ore as 180 catties, a picul of concentrate as 115 catties, and a picul of smelted tin as the usual 100 catties. No explanation was forthcoming for these standards beyond the fact that it was the custom.

At Kianghwa, to the west of Linwu, there is an extensive tin-field extending southward into Kwangsi and Kwantung provinces, which has by no means yet been thoroughly investigated. Native operations have been more or less confined to the alluvial deposit which is found on the tops and sides of the hills, being retained in depressions in the eroded and rugged surface of the limestone. The tin occurs in association with tourmaline, iron, and arsenic, and when dressed contains from 50 to 70% metal. The output from the entire district is considerably in excess of either of the two previously mentioned and would be greater but for the fact that the workers suffer much interruption and discouragement by brigandage. There are a few small tin mines situated in the mountainous country to the west of the Kuei river that produce a few tons of metal annually, but they are of small importance. Arsenic is derived as a by-product from the treatment of tin ore carrying arsenical pyrite as previously explained.

Quicksilver. This occurs to the west of Feng-huang-ting in western Hunan adjoining the Kweichow border, and forms the eastern end of a belt extending well into Kweichow province. The mines are reported to have been worked intermittently for several centuries and certainly the extent of the underground workings and the size of the waste dumps lend truth to this statement. The two mines at present operating are Hon-tze-ping, situated 21 miles west of Fengchuang, and Tatung-la, situated 28 miles south-west of that town. The cinnabar is found disseminated through a thickness of about 100 ft. of horizontal dolomitic strata in small crystals or blebs frequently associated with long radiating crystals of stibnite; occasional rich pockets of ore occur but the deposit is of lower average grade than Hon-tze-ping. At both mines the richer picked ore is crushed by hand and panned. This is sold direct according to grade, as estimated by the eye, to buyers from Tungjen in Kweichow. The market price at the beginning of the year varied from 110 to 170 strings per picul and it may be remarked in passing that all payments are made in copper coin. The poorer ore and tailing from panning are retorted by crude native methods.

Gold. Evidences of gold-washing of river sands are

plentiful but the operations do not appear to have been conducted with much profit, as only at two points was work seen in actual progress. Only a few mines are working and it is doubtful if these are remunerative. The chief of these is near Pingkiang in northeast Hunan close to the Kiangsi border, and 120 miles northeast of Changsha, the capital of the province. This company is controlled by the Hunan Official Mining Board, and controls a number of mines scattered over a mountainous district. The formation consists of a gray schist, carrying veins of quartz. There are numerous small workings dotted about the hillsides, most of which have been abandoned as either profitless or on account of inability to cope with the water. In most cases the adits or tunnels from the creek-banks were driven downhill, with the result that the working was, of course, flooded almost immediately.

The company is at present producing ore from six different mines, at distances varying from a third to 3 miles from the dressing-floor. The average width of the veins varies in the different mines from three inches up to two feet; the wider being generally composed of mixed schist and quartz. A small percentage of iron pyrite and galena is present. The principal mine, called the Kin T'ang is working two veins intersecting each other at an acute angle and dipping in the same direction. The veins consist of mixed schist and quartz and vary in width up to four feet, but the stope-widths are generally two feet or more in excess of this. This mine has been worked to a depth of about 650 ft. measured on the dip of 35 to 40°. The gold occurs in shoots and patches that decrease in depth. The mining is not run on contract; the miners are paid 214 cash per 8-hour shift and all tools and explosives are found by the company. The pump-men and ore-carriers are paid 164 cash per shift.

The process of treatment consists of the usual cobbing and sorting to eliminate the waste-rock. The sorted ore is then crushed in a man-power stamp-mill. This is built on similar lines to the old well-known rice-mill, except that the face of the stamp, corresponding to the shoe of the modern gravitation mill, shod with iron, strikes on a cube of iron, which corresponds to the die. The crushed ore is washed over two sets of riffle-tables, each table consisting of three boards, stepped, of a total length of 10 feet. The ore is fed by sprinkling on the head-board. The tailing is passed over the tables as often as is deemed necessary before going to waste; the concentrate is panned by hand and the free gold thus obtained smelted into ingots of 12 ounces. The remainder is fine-ground in small troughs in which an iron disc is rotated backward and forward by coolies rolling the axle on the soles of their feet. A similar appliance is used by Chinese chemists for grinding the ingredients of their medicines. After several concentrations by panning and re-grinding, the sulphides are roasted in a small reverberatory furnace and again fine-ground and sent over the riffle-tables.

The Kin T'ang mine has its own dressing-floors, the concentrate being sent over to the central mill only for final treatment. The official returns for the closing months of 1914 show that the grade of the sorted ore was about 0.75 oz. gold per ton and that the output averaged 120 oz. gold per month of a fineness of about 920.

Other gold mines exist at Suo-sha-po, Liu-lin-cha, and Huitung. The first named is situated 14 miles north of the village of Ta-fu-hsi on the Yuan river, in the Tao-yuan district. The deposit here consists of an interbedded quartz vein in sedimentary strata composed of quartzite and shale, much hardened and contorted in places. The method of working is by drifts and open stopes, although adits suitably situated would open several hundred feet of backs. The veins vary up to a maximum of 30 inches; visible gold is found but is mostly associated with pyrite, galena, and copper sulphide. A 7-dwt. ore is considered to be of good grade. The crushing appliance is a stone roller-mill driven by water-power. The riffle-board is employed as a concentrator and the concentrate is ground fine by hand between stones; the tailings are re-treated several times before going to waste. Until recently this field was illegally worked and the output at present is low.

The Liu-lin-cha mines lie some 7 miles distant from the village of that name in the Shen-chow-fu. Two companies are at work here on an auriferous mass which is apparently akin to a 'stockwork' (or accumulation of small veins and stringers) resulting from the infilling of fractures produced by a strong fissure. Neither company treats its own ore but sells it at the pit's mouth to the highest bidder. It is reduced in private mills of which there are fully 50 in the valley. The method of treatment is the same as at Suo-sha-po. The average grade probably does not exceed half an ounce of gold per ton, and the total production for the population of 3000 to 4000 is well below 100 oz. per month. It will be realized that the valley does not present a prosperous appearance. The Huitung mines in the Huitung district, in the south-western quarter of the province, were reported to have been closed-down recently. The geology here is stated to be similar to that at Ping-kiang.

"Chile has slightly over 3,600,000 people," writes a reader in Valparaiso, correcting a note in our issue of November 20. This is equivalent to 12.3 people per square mile, being only exceeded in density among South American countries by Uruguay. "The population of Santiago is 400,000 and Valparaiso 150,000," says the same authority. "In width Chile varies from 106 to 219 miles, while its length is 2578 miles. The shipment of iron ore during 1914 was 63,500 metric tons, in 1915 it was 154,000."

Copper production of Peru in 1915 totaled 31,890 long tons, compared with 25,070 in 1914, and 27,328 in 1913. Since August last year the Cerro de Pasco and Backus & Johnson plants have been at full capacity.

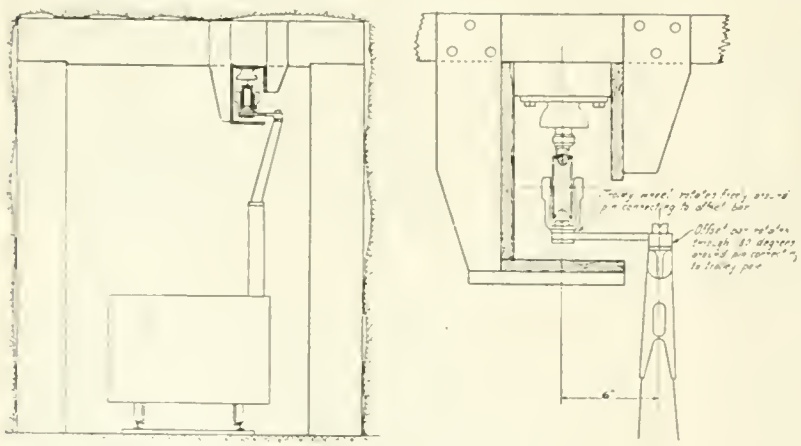
A Safety Trolley-Wire Box

During the past few years there have been several accidents in Butte mines, caused by men accidently getting into contact with the trolley wires used in connection with the electric-haulage system. Some difficulty has been encountered in providing satisfactory protection against such accidents. The guards generally used consisted of two boards placed in a vertical position, one on each side of the wire. On account of the fact that the trolley-pole and trolley-wheel were in a straight line and in a vertical position, it was impossible to protect the wire from beneath, and there was always the danger of a man carrying a drill on his shoulder touching the end of the drill against the wire.

The trolley-wire box and trolley-pole which are shown in the accompanying illustration were devised at the Steward mine for the purpose of eliminating this danger. The main features are: a trolley-pole which supports the trolley-wheel by means of a horizontal offset plate, and a horizontal board guard which prevents the wire from being touched by anything pushed toward it from beneath. The use of this board is, of course, made possible only by the use of the offset trolley-wheel.

As will be seen in the sketch, the side opening through which the trolley-wheel is brought into contact with the trolley-wire, should be placed opposite the near side of the drift. It is then practically impossible for a man to accidentally get anything into contact with the wire.

In case the trolley-wheel should jump off the wire, the horizontal offset piece will bear against the lower edge of the side board nearest the trolley-pole, and will prevent the trolley-wheel from doing any damage. When using the old type of guard the trolley-wheel sometimes jumped



AN UNDERGROUND TROLLEY-WIRE GUARD.

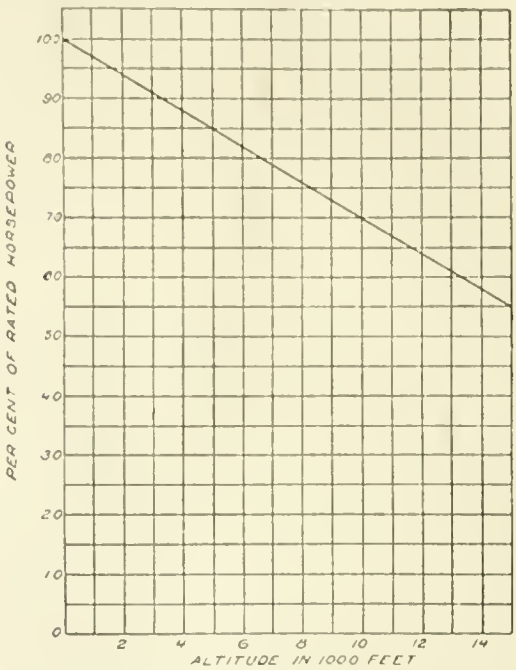
off the wire and tore off the trolley-wire supports before the motorman could get control of the pole.

This guard has now been in use on the 2800-ft. level of the Steward mine for two months and has given complete satisfaction. Any man who has been knocked down and dazed by a shock from a trolley-wire will appreciate the device here described.

*Abstract from *The Anode*.

Chart for Computing Gas-Engine Horse-Power

Gas-engines and altitudes were discussed by four engineers in the PRESS of November 13, and the following note should be of further value.



The horse-power that can be developed by an engine at a given altitude can be computed by multiplying the horse-power at sea-level by the atmospheric pressure at the given altitude and dividing by the atmospheric pressure at sea-level. Thus to compute the power developed by a 250-hp. engine at an elevation of 8000 ft., we have the pressure at that elevation equal to 10.9 lb. per square inch.

$$\text{Then } \frac{250 \times 10.9}{14.7} = 185.3 \text{ horse-power.}$$

The calculation is simplified by the use of the accompanying chart, which is taken from *Practical Engineering*.

UTAH'S production of metals in 1915 amounted to $55,000,000, an increase of nearly 50%, or $18,000,000 over 1914. The State's output of copper has increased rapidly during late years until 182,589,000 lb. was attained in 1915. The area of Utah is 84,970 square miles, which is almost exactly the same as Idaho. In population the two states are nearly the same, being about 400,000 each. By reason of possessing deposits of coal suitable for coking, Utah is an important smelting field.

A JANNEY flotation-machine and a Wilfley table have been presented to the Michigan College of Mines by the Mohawk Mining Co., Theodore Dengler manager.

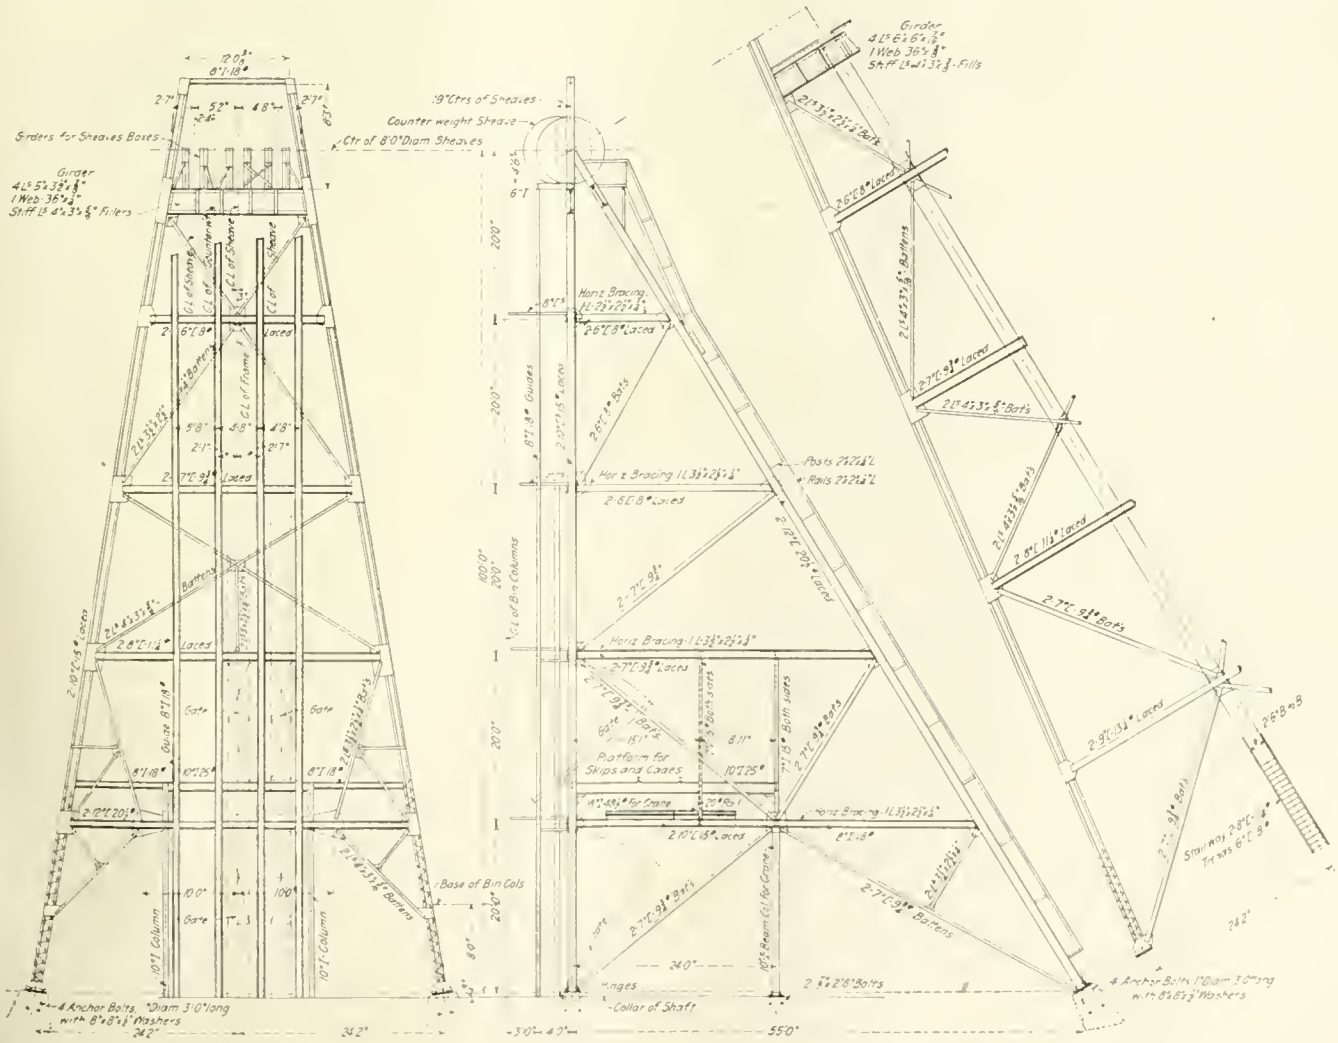
Notes From Grass Valley

By P. B. McDonald

THE narrow-gauge railroad from the Southern Pacific junction to Grass Valley indicates that the product of the mines of that district is shipped in gold-bricks rather than by great ore-trains such as leave Butte, the Lake Superior districts, or the Arizona copper mines. The snug little town of Grass Valley has the unmistakable atmosphere of American metal-mining communities, the same type of buildings and muddy roads, and the same quiet air of energy.

This famous gold-mining district is seven hours from San Francisco, at an elevation of half a mile. It is in the foot-hill country. Farms for dairy, fruit, and vegetables surround the mines, but in most respects these look much the same as other mines. In the window of the Chamber of Commerce is a gilded model, the size of a steamer-trunk representing the district's annual output of gold. 4½ tons valued at $2,500,000. Nevada county has produced $250,000,000 in gold since 1850, of which the quartz mines furnished over one-half.

The gold-bearing quartz veins are from a foot to four or five feet thick, and the ores range from $4 per ton in wide veins to $20 in narrow veins. The deepest workings are 6400 ft. on a dip of 23°, this bringing them to the sea-level. The North Star and Empire produce each a million dollars annually. The Empire has been operated for fifty years and is a close corporation; it recently erected a 60-stamp mill in which are the heaviest stamps in the district, 1350 lb., besides which it has 20 stamps at its Pennsylvania shaft. The North Star operates two 40-stamp mills. Both mines have cyanide-plants. The Golden Center is a rejuvenated little mine in the heart of the town that had pumping trouble in early times from a creek near the shaft. A 10-stamp mill treats the ore by amalgamation and concentration; devel-



THE NEW STEEL HEAD-FRAME AT THE NORTH STAR CENTRAL SHAFT.

opment at depth is promising, and additional stamps will soon be required.

Two miles east of town near the rich old Idaho-Maryland vein, a famous bonanza of an earlier generation, are the Brunswick and Union Hill mines. The former has operated persistently for 26 years and paid dividends for the past two years; recently it added a 20-stamp mill of 1250-lb. stamps, a steel head-frame, and new machinery at the vertical shaft close to the railroad. This equipment supplements the old plant at the incline-shaft alongside a 20-stamp mill of the customary 1000-lb. stamp. The Union Hill mine, adjoining the Brunswick, is believed also to be on a branch of the Idaho-Maryland vein. The Union Hill has a 20-stamp mill and does not concentrate, extracting its gold by amalgamation; occasional patches of scheelite have been found and shipped to buyers in Colorado and San Francisco.

The new mill at the Brunswick has clean-up pans of revolving bowl and balls. The mill is driven electrically with separate motors for the vanners, stamps, and crushers; Wilfley tables will be added. When the equipment at the new shaft is complete, the skips will dump directly into the mill; there is no cyanide-plant, the concentrate being shipped to a chlorination works at Nevada City. The two-post steel head-frame at the vertical shaft has an unusually short base; by reason of lack of room the back-brace is inclined at a steeper angle than ordinary; the centre of the sheave is 85 ft. above the collar while the back-brace has a base of only 30 ft. The head-frame was built by J. R. Cahill of San Francisco; the cost being $5500.

The North Star likewise has a new two-post steel head-frame, built by the Minneapolis Steel & Machinery Co.; it is 100 ft. high to the sheaves, and contains 96,000 lb. of steel. The accompanying sketch shows the design of this head-frame. The back-brace has a base of 55 ft., which is over half the distance to the centre of the sheaves. The posts, back-brace, and horizontal members are laced. As skips and cages have to be changed two or three times daily, the cages are kept on a platform 25 ft. above the ground, where they are out of the way. This is better than having them at the collar of the shaft where space is at a premium.

The new hoist at this shaft is operated by compressed air; it is a Nordberg duplex-engine with the elaborate Nordberg devices; the cylinders are 28 by 48 in., each skip weighs 5000 lb. and holds four tons. At the hydraulic power-house, a half-mile from the mine, is a Laidlaw-Dunn-Gordon air-compressor direct-connected to an 18-ft. Pelton water-wheel. This large wheel is necessitated by the low speed of the compressor to which it is direct-connected.

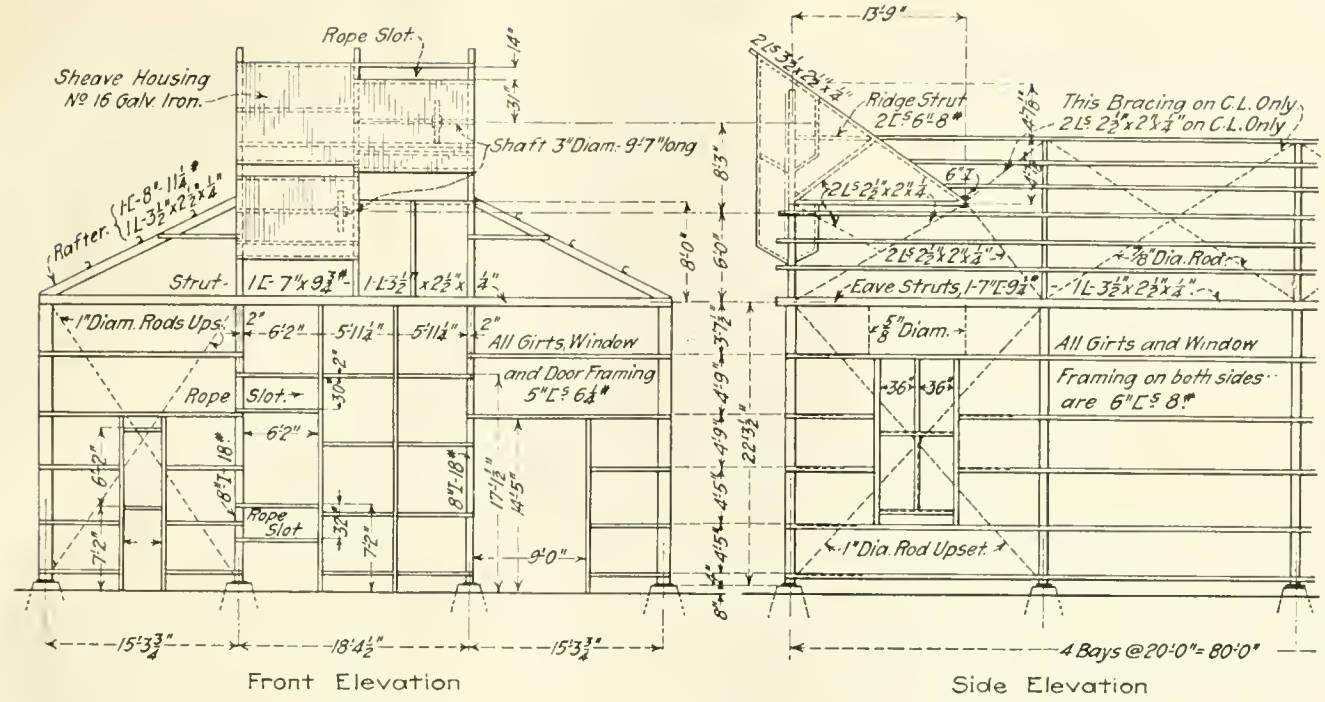
Electric-power is used both for stamp-mills and mining. At the Brunswick I noticed an electric hoist; incidentally, it was fitted with the increasingly popular herring-bone gears. There are several direct-connected electric air-compressors of the type that make known their presence in engine-rooms by the peculiar 'clucking' noise that accompanies the regulation for the varying demands for air in the line. Electric pumps are much used, both the centrifugal and plunger types. The North Star has a 10-stage centrifugal that pumps against a head of 1400 ft.; its capacity is 400 gallons per minute, and the efficiency in tests has stood at 65%.

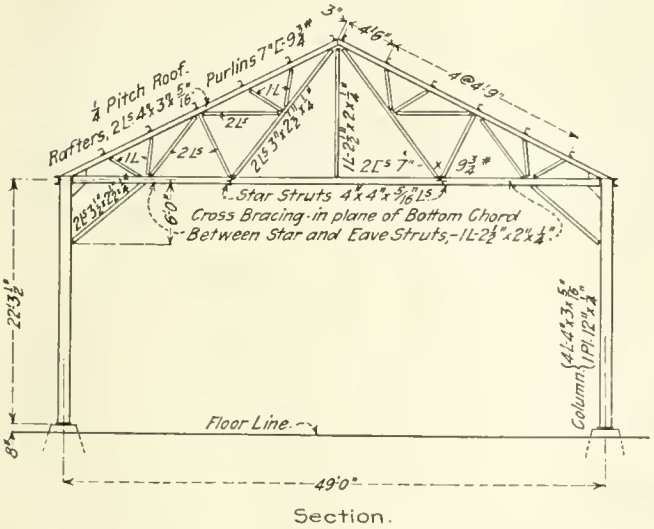
At the vertical shaft of the Brunswick I observed a two-stage centrifugal pump mounted in a frame to run on guides in the pump-compartment, a handy method of hanging a pump so that it can be lowered or raised easily. With a centrifugal pump held flatwise in the frame no elbows are needed in the inlet or discharge at the pump; for an incline-shaft the pump would be mounted on a flat-car; this device is not new, but had not been adopted at small mines until lately.

At the incline-shaft of the Brunswick there is an old hoist driven by a Pelton water-wheel regulated by a Chavanne needle-nozzle; it is friction-driven by a fibre pinion and hoists 1250 ft. on the incline. At the top of the incline head-frame at the Empire is a compressed-air safeguard against over-winding; this consists of two cylinders connected to the compressed-air line, with a play of 4 ft. for reducing the shock in case the hoist-engineer is careless and starts pulling the skip through the top of the head-frame. A trip flashes a light in the engine-room when the skip is ready to dump, and there is a catch for automatically stopping the engine as soon as half of the 4 ft. is exceeded.

The new engine-house at the North Star is economically constructed of corrugated-iron sheets covered with a thin layer of asbestos on both sides and fastened by 'purlin-nails' (short wire hooks) to a light steel framework, making a tight structure that does not rattle in the wind. The absence of snow-load simplifies the roof problem, the roof being of the same material as the sides. Such a building, popular in mild climates, might not be satisfactory in the rigorous winters of northern regions. The roof-truss is shown in the sketch.

Some tendency is evident, as in several other American districts, to raise the grade of ore by hand-picking on surface and by decreasing the stoping-width underground. At the North Star during the three months ended October 2, a total of 24,414 tons of ore was hoisted as compared with 25,325 tons during the previous quarter, while the miners' shifts increased from 4133 to 5081. The tons per miner decreased from 6.14 to 4.81, but the sticks of dynamite increased from 79,408 to 95,448, and the tons of ore hoisted per square foot of stoping-area fell from 0.415 to 0.352. At first sight this looks as though the underground efficiency had deteriorated, because, although more shifts were worked and more dynamite was used, the output of ore decreased. This was not the case, but the decrease in output was due to narrowing the stoping-width and to increased sorting underground. This is one indication of the reaction now evident against striving for tonnage while disregarding the ultimate purpose—that of making money. Apropos is the old story told at Lake Superior of a visiting engineer who was watching the hoisting at a copper mine; observing that the rock dumped was barren sandstone





THE NEW ENGINE-HOUSE AT THE NORTH STAR MINE.

wall-rock instead of ore, he inquired of the foreman why such material was being hoisted; the foreman replied "We've got to keep those stamps going somehow." At the North Star the average stoping-width has been decreased 18% or from 4.5 ft. to 3.7 feet.

An interesting innovation is the hand-picking at the shaft. The ore, passing over the grizzlies spaced at 1¼ in., is fed onto two shaking-tables at which six men, three at a table, piek and east behind them onto a conveyor-belt all rock that contains no quartz. The ore is fed forward by shaking into two jaw-crushers. The picking is aided by water sprayed on the ore; this water is afterward piped to the mill for use there. Six men, working on day-shift, are able to piek the accumulation in the bins of the night before in addition to the day's hoist, easting away as waste over 10 tons per man, or 60 to 70 tons that was formerly sent to the mill, where it cost 90 cents per ton to treat. While it is early to give definite figures, the indication is that the grade of ore sent to the mill will be raised about $1.50 per ton by the picking. A benefit already noticed is the increase of 10% in the amount of ore crushed by reason of the greater ease with whieh quartz, or mixed quartz, can be crushed in comparison to the less brittle waste-rock. The flattening of the veins, almost to the horizontal at depth, tends to increase costs. In flat stopes it becomes necessary to extract a wider portion of the vein to allow the miners room to stand; also tramming costs increase, and water settles in the hollows. Mules are used for underground-haulage in the larger mines.

Electric haulage in the Copper Queen mine is on alternate levels, there being seven sueh haulage-levels. The gauge of the track is 20 in., and the rails are 25 lb. per yard. The heaviest locomotive weighs 14,000 lb. The weight of a loaded car is rarely above 6000 lb. At the larger stations sufficient double track is laid to hold 20 ears. Standard switehes on curves of 40 to 80 ft. are used. D.C. is of 250 volts; and trolley-wires are, as required by law, 7 ft. above the track. Several men have been killed by coming in contaet with the wire when their shoes or hands were wet. Carrying tools on the shoulder is against the rules. To reduce the breaking of trolley-poles in turning in narrow drifts, a trolley-pole with a knuckle in the centre was adopted. These notes are abstracted from a paper by Gerald F. G. Sherman, read at the San Francisco meeting of the A. I. M. E.

T. F. Cole, well known in eopper mining eireles, is taking an interest in his boyhood home in the eopper country of Michigan. In addition to his financing of Keweenaw Copper Co. to explore a large area of old copper-bearing territory, he recently bought the mineral right under the town of Ahmeek, paying $4000 per acre for 40 acres.

Dredging in the United States

By H. D. McCaskey

THE production of gold by dredging in the United States and Alaska from the commercial beginning of the industry in 1896 to the record output of 1914, inclusive, has amounted, according to best available data, to $94,833,468, and the value will probably have passed the $100,000,000 mark by the middle of 1915.

Profitable dredging for gold is first noted from Grasshopper gulch in the Bannock district, Beaverhead county, Montana, where a Bucyrus double-elevator bucket-dredge was operated as early as 1893-'94. Before that time, and only too frequently since, dredging operations had been attempted in various regions only to fail because of insufficient knowledge of the ground or of the engineering and financial features of the work. Dredges of various types have been tried without permanent success—clam-shell, suction, single bucket, spoon or scoop, and pump—until finally has been evolved the modern bucket-elevator machine of wonderful capacity and endurance, fitted, according to the special conditions involved, to overcome natural obstacles that have blocked earlier attempts, operated in many cases by electric power, and profitably treating material unprofitable under all other known or attempted methods of operation. From the Bannock district dredging extended to Alder gulch, near Ruby, in Madison county, and operations have been continuous in Montana since, with a total yield from this source of more than $6,500,000. In Idaho, where the gravels of the Boise basin have been worked by this method, dredging has produced nearly $3,000,000 and been continuous since 1897. In Colorado dredging has been in vogue in the Breckenridge district, Summit county, since 1901, and has produced over $2,700,000 in gold. In New Mexico, from 1902 to 1905, inclusive, a dredge was operated on Cimarron river, near Elizabethtown, in Colfax county, and added materially at that time to the gold output of the State. The gravels finally became too poor to operate, according to report, and work came to an end. In Alaska, dredging has been continuous and of increasing importance since 1903, and is now an important factor in the production of gold—over $10,000,000 to date. In Oregon, dredging has not been always profitable, but it has been almost continuous since 1904, and in 1914 it was reported as notably successful. In the Philippine Islands dredging had its inception under the Spanish régime in a curious native boat of diminutive scale, but was first tried by modern American methods (unsuccessfully) in Masbate in 1905. Later New Zealand and American dredges were introduced into the Paracale-Mambulao district, south-eastern Luzon, where the first native dredging was done, and the development of the industry has been continuous since. One modern

*Abstract from 'Mineral Resources of the United States, 1914,' published Jan. 20, 1916.

dredge alone had recovered more than $450,000 in less than 2½ years to the end of 1914, and had paid 107% interest on the original capitalization of $250,000. There were eight dredges at work in 1914 in the Islands, seven in this district and one in Tayabas, and they produced altogether during the year about $515,000.

In California some of the earliest attempts at dredging for gold were made, following the first successful work of the kind with steam-driven bucket-elevator dredges at Otago, in New Zealand, in 1882. But it was not until 1896 that the first commercial bucket-elevator dredge of the California type was operated on the Yuba river. It was later wrecked by floods, but it began the great output of gold from California by this method which had amounted to over $71,000,000 by the end of 1914, in which year 60 boats altogether were at work in the various fields. Much of the proved dredging ground in California has now been worked out, and it is an open question whether development of new ground will in the future take the place of that worked out. In the evolution of dredging apparatus from the small steam-driven wooden machines with buckets of a capacity of about three cubic feet each and capable of raising 1200 cu. yd. daily to the great all-steel electric-driven dredges with buckets raising 16 cu. ft. each, and handling 10,000 cu. yd. daily, California has earned first rank. It is becoming better known that a great deal of dredging in various parts of the world has been at a loss, and that many important factors enter into the problem as to what ground can be worked at a profit by this method. The industry has now developed geologic, engineering, and constructing experts, and, in view of the fact that even profitable dredging is expensive in outlay, prospective investors would seem to gain something by consulting the rich fund of experience now available in the hands of these specialists.

Brief details of dredging operations have been given in 'Mineral Resources' in the mines' reports on gold, silver, copper, lead, and zinc of the Western States, and also in earlier reports of the Director of the Mint. Further information is to be found in reports of geological surveys or mining officials of different States. A comprehensive and very useful report is contained in Bulletin 57 of the California State Mining Bureau, 'Gold Dredging in California,' by W. B. Winston and Charles Janin. Another valuable treatise is 'Dredging for Gold in California,' by D'Arcy Weatherbe, published by the Mining and Scientific Press; and additional information is constantly furnished by the technical press.

The preceding table, compiled from best available sources, gives the dredge production of gold in the United States and Alaska (not including the Philippine Islands) from 1896 to the end of 1914, inclusive, by States.

Electro-statics. That branch of electrical science devoted to the phenomena of electricity at rest or of frictional electricity.

Metallurgy of Native-Silver in Chihuahua

By W. M. Brodie

*The native-silver ores of Chihuahua were known in the seventeenth century, as soon as the Spanish settlers occupied that part of the country. The special attraction of these ores was that anyone could melt them in an ordinary forge into cakes of silver, that served as money. The low-grade ores were considered of no commercial value until 1880, when ex-governor Shepherd visited the place, bought the San Miguel group of mines, and commenced to explore on a large scale. He lived in Batopilas for over twenty years and died there in 1902.

The ores formerly were carefully hand-sorted. The rich ores were pounded fine by hand, the native silver sifted and washed out, and the remainder ground in drag-mills with mercury. The amalgam was separated by washing, packed in flasks and the mercury distilled, leaving silver to be melted and refined in the vaso.

Nowadays the rich ores are separated. They are crushed in a special stamp-mill and the coarse silver is taken out of the mortar and melted. The pulp passing through the screen is treated in amalgamating-pans with mercury, and the tailing is leached with cyanide solution by agitation. The low-grade ores are crushed in a larger mill also driven by water-power. The pulp is concentrated on shaking-tables, the tailing goes to the river, and the concentrates are re-concentrated. The richer part holding native silver is treated in the amalgamation-pans like the high-grade ores, and the poorer part of the concentrates is leached with cyanide solution by percolation.

The native silver and argentite concentrate well. The rate of concentration is 50 to 1. The fine black silver in the concentrate and tailing is easily dissolved with a cyanide solution. The low-grade ores have furnished in late years one-third of the total production. The crude silver from the stamp-mills, from the amalgamation, and from the cyanide process is refined in a reverberatory furnace to total fineness.

New-style drill bits of the Carr type are being employed at the New Almaden quicksilver mines in Santa Clara county, California. In this medium-hard rock with occasional soft streaks, it is found advantageous to punch a hole in the side of the hollow drill-steel an inch or two from the end of the bit rather than depend on the hole in the centre of the bit which is likely to become clogged with muddy rock-chippings. As mentioned in the article on drill-bits in our issue of November 6, this is not an unusual practice with Carr bits for mounted hammer-drills, and is done at Lake Superior mines where varieties of iron ore are not unlike the California cinnabar in drilling qualities.

*Abstract from paper read before the Pan-American Congress, Washington, December, 1915

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

QUICKSILVER DEPOSITS of California, with few exceptions, are situated in the Coast ranges.

CENTRIFUGAL PUMPS will pump gritty water and pebbles. If special blades are provided, rocks as large as a man's fist can be handled.

A STEAM-SHOVEL at the Calumet & Hecla mine, Michigan, was used to advantage in removing snow during the heavy fall of January.

THE SHAPE OF SHOVELS is important. A small round-pointed shovel is best for tough soils; a large square-pointed shovel for handling sand, gravel, or coal, off boards.

SHAFT-SINKING cost at Butte, in one instance, was reduced from $45 per foot to $36 per foot by putting the miners on a bonus system; 106 ft. was sunk in 30 working days.

BLACK SHALE, containing bituminous matter, pyrite, and marcasite stored on the edge of the Tennessee river, near Hamburg, recently caught fire after several days of rain. The pile of shale contained all the conditions necessary for spontaneous combustion. Coal frequently catches fire, but shale is rarely attacked in this way.

THAT A STERLING BILL payable on presentation in current and legal funds in London must be sold in New York at from 18 to 36 cents discount in the pound means merely that in London one cannot have the gold for the bill—else the present rates of bank, freight, and insurance charges could allow of a discount of not more than 3 cents.

GEARS cannot be operated safely at too high a speed, or the liability to shock becomes dangerous and the noise excessive. For ordinary cast-iron gears 1800 feet per minute is high, for helical cast-iron gears 2400 ft., for cast-steel gears 2400 ft., for special cast-iron machine-cut gears 3000 ft. Rawhide gearing, which operates almost noiselessly, may be run satisfactorily up to 3000 ft. per minute.

SHAFT-SINKING practice in the Lake Superior region is exemplified by the rate of advance made in the Woodbury vertical shaft of the Newport Mining Co. at Ironwood, Michigan, details of the method of sinking of which were described in our issue of November 13. The shaft is 13 by 21 ft. in size, has six compartments, and much of the rock is granite. On December 1 a depth of 1664 ft. had been attained, making an average of 185 ft. per month, or approximately 6 ft. per day, which is noteworthy. Sinking will be continued to a depth of 2400 feet.

HIGH PRICES for zinc are responsible for much activity that is not always profitable. In the Joplin district of Missouri pillars of ore are left to support roofs. In one instance, a pillar 8 ft. high and 25 ft. thick, contained 300 tons of 2.5% ore, worth $750, and a profit of $350. This pillar was mined, with the result that a slab of waste, 65 by 65 by 3½ ft., weighing 1100 tons, fell, costing $200 to shovel it away, and $350 for other charges. Here the operator risked losing $220 in order to recover $350 profit, not mentioning the risk to the lives of miners, according to Walter Holmes, a mine inspector.

COMPRESSED-AIR HOISTS are becoming popular at those mines where the use of steam has declined by reason of the substitution of electricity. A hoist at the Copper Queen mine that had been driven by steam, was changed to compressed air without making any alteration in the engine; compressed air was found to be more efficient than steam, as the steam-main was 920 ft. long. By employing cold air in the cylinders for brakes and clutches, leakage and packing troubles became negligible; however, the air for the engine is heated to 250°. At one hoist of the Copper Queen 1,000,000 cu. ft. of free air, compressed to 92-lb. pressure, is required daily.

DESIGNATIONS of various grades of cyanide, based on sodium cyanide content, was described on page 74 of the PRESS of January 8. As sodium cyanide has displaced the potassium salt, the previous 129% sodium salt, containing 51-52% cyanogen, is now 96-98%, with the same composition. To show the trend of use of the two salts, the following figures, compiled by the Survey, are of interest:

State.	Potassium cyanide.		Sodium cyanide.	
	1913.	1914.	1913.	1914.
Colorado	659,374	35,800	260,589	935,589
New Mexico	1,415	.....	190,190	237,511
South Dakota	113,727	89,649	388,961	425,397
Total	774,516	125,449	839,740	1,598,497

EXPLOSIVES are stored underground in many mines, in a room apart from the active workings, preferably on a level where mining has ceased. While objection is sometimes raised to the storage of several days' supply of dynamite underground, there is reason to believe that less danger exists in such cases when carefully conducted and distributed by a capable 'powder-monger' than in a system whereby dynamite is taken underground each day by various miners or foremen, as the handling of it is lessened. Charles E. Munroe recently pointed out in a paper at the Second Pan-American Scientific Congress at Washington, that in an underground magazine it is well to arrange a 'safety-valve,' such as a lightly closed shaft above the magazine that will provide a vent similar to the explosion-doors on blast-furnaces and stoves in case of an explosion. He also spoke against the storage of black powder with the dynamite, as one tends to deteriorate the other by the absorbing of moisture from a hydrated explosive by a dry explosive.

Mining in Colorado

By George J. Bancroft

COLORADO increased its output of gold, silver, lead, copper, and zinc from $33,000,000 in 1914 to $43,000,000 in 1915, a gain of $10,000,000. But the major metals represent only a part of the State's mining activity. Colorado leads in the production of rare metals, the increase in the value of which was $2,700,000. Tungsten increased from $293,500 in 1914 to $1,785,000 in 1915; manganese increased from nothing to $625,000; radium decreased from $150,000 to $100,000; vanadium increased from $100,000 to $600,000; molybdenum increased from nothing to $400,000.

Colorado produces a variety of other minerals, as follows:

Marble	$ 1,000,000
Coal	18,000,000
Chemicals	3,639,453
Fire-clay	50,000
Portland cement	500,000
Petroleum	200,000
Hydro-carbons	100,000
Lime	80,000
Clay products	1,200,000
Total	$25,069,453

This amount, added to the production of the common and rare metals, shows that the mineral industry in all its branches produced $71,500,000 last year.

The future of the State's mining looks to the diversity of mineral output rather than to great increases in gold and silver. For many years, Colorado was famed chiefly for its production of the precious metals. I would say that the gold and silver product of the State will soon be a matter of relative secondary importance. Furthermore, I hazard the forecast that the metalliferous mining will be secondary to the non-metalliferous mining. Colorado has been known as the leading bi-metallic State. It is now the leading multi-metallic State, and it bids fair to soon become one of the leading multi-mineral states.

A hopeful feature of the silver market has been given publicity by Catlin & Powell Co. of New York, to the effect that the cinematographs or 'movies' are now buying 15,000,000 ounces of silver annually. A salt of silver is used to sensitize the films. It is evident that this film business is destined to play an important part in the future of the silver market.

An enterprise of much importance to the San Juan has been started at the Camp Bird, namely the driving of a 9000-ft. adit to work the famous vein at depth. This enterprise has a great geologic interest. A number of the profitable San Juan mines are situated in the andesitic overflows, which are underlain by a conglomerate bed of Miocene age. It is generally recognized that the conglomerate is the lower boundary of mineral enrichment, and even the beds immediately overlying it are considered unfavorable to orebodies.

Fresh discoveries of tungsten have been made in the Cement Creek part of the San Juan region. Silverton was shut off from the outside world for thirty days, but in spite of this fact, important discoveries are reported. In fact, one discovery is said to be due to an unusually heavy snow-slide that plowed the soil off a mountainside.

At Leadville, Jesse McDonald's famous pumping project at the Penrose shaft is now one of three similar enterprises. Fryer hill and Carbonate hill are to be unwatered. Fryer hill is to be unwatered by the United States Smelting, Refining & Exploration Co., resident manager H. S. Lee. The Harvard shaft will be used for pumping, the machinery being already on the ground. Centrifugal station-pumps of the Krogh type will be used. The maximum lift will be 750 ft. and the capacity 700 gal. per minute. The U. S. S., R. & E. Co. recently floated $12,000,000 in ten-year gold notes through Lee, Higginson & Co. of Boston, which seems to indicate that they will take over properties now under option. Carbonate hill is to be unwatered by a company organized to develop the Pyrenees, R. A. M., Mikado, and Gallagher mines under a five-year lease. Some of the money comes from New York, which is also headquarters for the Iron Silver Mining Co., capitalized at $10,000,000, managed by George O. Argall and prominent as a shipper of zinc-lead ore. It pays dividends of $50,000 at least twice per annum. From reports submitted by the engineers, the company expects to pump an average of 2000 gal. of water per minute from a depth of 1300 ft., a greater distance from surface than is involved in either the Penrose or Fryer hill enterprises. With capacity for 2000 gal. per min., the Carbonate pumps will rank third in Colorado and next to the Smuggler at Aspen, which is quoted at 2500 gal. and where incidentally the high price of lead, 50% above normal, has stimulated production.

The dredges are shut-down during the winter. A few years ago the Reiling dredge at Breckenridge ran all winter. Although it was proved that the winters do not limit successful dredging, a dredge needs overhauling once a year, so the boats stop work in the colder part of the winter. This year promises to make a record in placer mining.

Buyers of rare metal ores in Denver are thick as flies in honey, and their main worry appears to be to obtain a dependable supply for a long period. Price seems a secondary matter with them. The prices of alloy-steel are such that the cost of the small proportion of the rare metal required is susceptible to considerable latitude.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

DEADWOOD, SOUTH DAKOTA

NEED FOR CUSTOM PLANT.—TUNGSTEN PRODUCTION.—HOMESTAKE ACTIVITY.—ORO HONDO.—RICH GOLD ORE AT RATTLESNAKE JACK MINE.

A custom-cyanide plant for Deadwood is a topic of discussion just now, and probably the mining committee of the Deadwood Business Club will investigate the matter fully; should it make a favorable report the mill undoubtedly will be built. It is pointed out that there are a large number of small properties, capable of supplying 10 tons or more of ore daily, not large enough to support a mill of their own, but combined could furnish a good quantity. Several such properties have been opened in the Blacktail district; others in Two Bit, Spruce gulch, and Bald mountain section can always be depended on to yield a good tonnage. Deadwood would be an ideal location for the mill. It has railroad connections, both narrow and standard gauge, with the mining camps; any one of several mill-sites could be secured; labor and supplies are plentiful. It is probable that the plant could be financed entirely with local capital. Several of the smaller mining companies would subscribe to the building fund, and local business men and investors could take care of the remainder. It is argued that the small mining companies would by this arrangement have their ore treated in a modern mill, which would be under the management of a first-class mill-man, at a moderate cost—no more than the treatment charge made at other plants—and that their dividends on the mill operations would still further reduce the net cost to them of treatment of their ore.

Production of wolframite continues at the Homestake and Wasp No. 2 mines. At the latter the concentrator is working well, and the first consignment of concentrate will be shipped about the end of February. The Wasp No. 2 paid a dividend of 5c. per share in January, and 2½c. in February. It appears that those who purchased the John Gray stock, sold by his administrators at 35c. per share, are almost reasonably sure to have their investment returned in dividends within the year. The Homestake is now loading its second car, which has been purchased by the Primos company.

The Homestake's Ellison shaft is to be continued to the 2000-ft. level; it is now 1920 ft. deep, or 70 ft. below the 1850-ft. station. From the new bottom a drift will be driven to a point beneath the B. & M. shaft, and connection made with that shaft, thus making it 2000 ft. deep also. For the sinking of the Ellison an auxiliary hoist will be installed at 1850 ft., and the compartments used for hoisting from that level to the surface will be bulkheaded to protect the men in the bottom. Work is progressing rapidly to completion on the installation of the new equipment at the B. & M. shaft. The crushers and conveying system were recently tested, and by the time the boiler-plant is finished the new hoist will be ready to go into commission. When this is done the boilers now in use at this shaft will be torn-out, and the space they occupy given to housing an immense air-compressor. Altogether the new equipment will be as good as possible to procure. It is expected that 1200 to 1500 tons daily will be hoisted here, or about one-third of the ore supply for the mills. Edgar Huntley and Ole Danielson, general foreman and night foreman, respectively, are no longer on the pay-roll. The former has resigned on account of ill-health, and has been succeeded by A. J. M. Ross, a member of the engineering corps. Mr. Danielson, who recently died, has been succeeded by John Townsend. All four of the men mentioned have been long-time employees, and won their various promotions strictly on their merits.

THE BLACK HILLS REGION OF SOUTH DAKOTA.

Mr. Ross, for instance, is a Lead product, leaving school to join the engineering staff, and working his way upward by ability.

At the 2000-ft. level of the Oro Hondo shaft excavation is now being made for a station. An extensive campaign of lateral work is contemplated for this level.

Exceptionally high-grade ore continues to be mined from a small streak in the Rattlesnake Jack property, near Galena.

The seam is 12 in. wide, and assays as high as $2000 gold per ton. Much of it is specimen rock. The mill is treating about 50 tons daily, by a combination of concentration and cyanidation. The concentrate—pyrites—contain $150 gold per ton; the last car shipped comprised 27 tons and returned $3800 net.

TORONTO, ONTARIO

Heavy War Tax Worries Mining Companies.—New Mills. Development, and Returns.

The proposed new war tax bill presented to the Canadian parliament on February 15 by Sir Thomas White, finance minister, has created much dissatisfaction in mining circles, as it hits the mining industry more than any other. The tax, from which it is expected to raise at least $25,000,000, is levied on the net profits of all classes of business, with the exception of life insurance, farming, and stock-raising, with a capital of $50,000 or more. Incorporated companies are taxed 25% on all net profits over 7%, and individuals, firms, and associations not incorporated, 25% on all net profits over 10%. The minimum capital limitation does not apply to those having war orders. The tax is made retroactive, covering a period of three years from August 3, 1914. The obvious objection from the standpoint of the mining investor is the injustice of placing mines on the same basis as other productive industries, as the assets are steadily depleted in the course of production, and the dividends largely consist of returns of capital. A high rate of interest is necessary to make the enterprise remunerative. Another objectionable feature is that under the bill as it now stands, companies having large capitalizations, mainly representing watered stock, and consequently yielding comparatively small dividends, will escape paying a due share of taxation. The retroactive clause is also strongly opposed on the ground that those companies which have already distributed their profits will be seriously embarrassed. It is understood that a strong deputation of mining men will shortly place its views before the Government. The finance minister has intimated that the bill may be modified as affecting mining companies.

A mill is to be erected at the North Thompson mine.

At Cobalt the Coniagas new cyanide plant for low-grade concentrate is in operation.

At the Chisholm Veteran claim near South Porcupine, five drill-holes are to be put down 1000 ft. each.

The McKinley-Darragh-Savage company pays 3% on April 1. The total is 199% equal to $4,471,890, or almost twice the capital.

During January the McIntyre property at Porcupine produced gold worth $71,076 from 8950 tons of ore. The profit was $38,400.

The new mill of the Schumacher is treating 110 tons of ore daily, averaging $8 to $10 per ton. The plant cost $57,800. It employs the Dorr counter-current decantation system.

During 1915 the Dome Lake Mining & Milling Co. of New Liskeard produced 11,727 tons of $9.12 ore, at a cost of $3.83 for underground work, and $2.45 for treatment. The net revenue was $80,659.

During 1915 the Trethewey Mining Co. of Cobalt only operated for the first two months. A fair amount of development was done. Reserves are 26,774 tons, containing 507,339 oz silver. Production from 6113 tons was 85,004 ounces.

During January the Nipissing high and low-grade mills treated 81 and 5278 tons of ore respectively, for a yield of $63,582 and $116,220. The refinery shipped 251,676 oz. silver. Development generally was satisfactory. An extension of the Trethewey vein was found, assaying 3000 oz. over 6 inches.

At the Tough Oakes, Kirkland Lake, the new compressor will allow of 30 drills being worked, instead of 17 during December. During that month the mill treated 3668 tons of ore averaging $20 per ton. Development continues good.

KALGOORLIE, WESTERN AUSTRALIA

Wood-Cutters on Strike.—Contract Troubles.—Wet Mines.—Mine Sale.—More Wage Disputes.—Yield of Mines.

During December, there appeared to be fairly general dissatisfaction among the wood-cutters, who supply the mines with firewood and mining timber. The majority of these men were Italians and Austrians, and, as the latter have been interned, and many of the former have gone to fight in Italy, and new men who are not used to the work have taken their place and cannot make standard wages, they are asking for higher rates. As none of the mining companies hold more than one or two months' supply, a strike would be serious, and this is what happened early in January, resulting in gradual shutting-down of the mines and mills.

A largely attended meeting of the Miners' Union was held in the third week of December, with the view of putting the contract system of working on a uniform and more equitable basis. The trouble has arisen owing to some of the companies charging more than $11 a case for explosives, the maximum rate stipulated. Another and more serious grievance is the fact that contracts, except in name, are not really contracts at all. No tenders are ever called for. The manager, or assistant, merely gives the job at a price, picks out some men, and they may take it or leave it. If one party refuses, another party is generally found that 'scabs' their mates. Naturally this leads to bad feeling. The system is intolerable, as really good workers pay their car-men and shovelers a 25 to 50c. bonus, in addition to the ruling rate paid by managers, whose employees the car-men are, and the remaining car-men are consequently dissatisfied. This is a long-standing grievance.

At the Edna May mine, near Southern Cross, the three electric pumps have an aggregate capacity of 1,400,000 gal. of water per day, and the Cornish lift 100,000 gal., a total of 1,500,000 gal. The adjoining mine, the Edna Deep, makes 2,880,000 gal. per day. The latter's shaft down to 300 ft. is practically dry; this was accomplished by means of plugging the bore-holes which cut the lode and putting down new vertical bores in the bottom of the shaft, and filling them with cement under high pressure.

The Associated Northern Blocks Co. has bought for $425,000 the Slippery Gimlet mine, almost adjoining its Victorious leases at Ora Banda. This mine has been stoped in the oxidized zone for a length of 480 ft. from 150 ft. to the surface, and produced 30,100 tons for $340,900, an average of $11.32. Telluride occurs both in the Victorious and Slippery Gimlet, which are only 660 ft. apart.

The Meekathara Miners' Union has asked the Arbitration Court for a revision of the award given in November 1910, and the Court has agreed to reconsider the question, the new agreement to date from January 1, 1916. The only two regular producers and profit-earners in the district are the Fenian and Ingliston Consols, both owned by private syndicates. During November their profits were $31,900 and $20,200, respectively. The Ingliston Extended, owned in London, has never paid a dividend, and has merely been developing lately, while the Queen of the Hills, owned by the Lake View & Oroya Exploration Co., has depleted its oxidized reserves, and has recently been altering its treatment plant. The other mines in the district have only intermittent crushings of small tonnage and are chiefly worked by their owners. Yet the total output of the district is considerable.

During November the State's mines yielded gold worth $2,124,000. The total to date is $624,000,000, and $128,000,000 in dividends. Some January returns were as follows: Horse-Shoe, 7412 oz. from 16,116 tons, with $32,000 profit; Ivanhoe, 7289 oz. from 19,123 tons, with $43,000 profit; and South Kalgurli, 2911 oz. from 10,022 tons, with $9600 profit. Costs at the last were $4.32 per ton. Spare lathes at Kalgoorlie are now used to turn shells for the army.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The total trade of the Territory in 1915 was $82,871,122, an increase of $12,368,254. Exports amounted to $54,856,815, including antimony, $189,345; copper ore and matte, $12,351,163; fish and fish products, $19,655,239; gypsum, $65,800; lead ore and matte, $31,476; marble, $104,888; tin ore, $79,471; and gold and silver, $16,090,411. Shipping amounted to 1609 vessels of 1,027,727 tons.

Juneau

On February 28 the Alaska Treadwell and Alaska United companies paid 75c. and 30c. per share, respectively.

ARIZONA

Cochise County

During January the Shattuck-Arizona mine produced 531 oz. gold, 30,369 oz. silver, 267,853 lb. lead, and 1,565,224 lb. copper.

In order to protect itself against possible fluctuations in copper, the Copper Queen company has informed custom ore producers in Mexico that new rates will be effective on March 15.

Gila County

In its mining and livestock edition of 36 pages the *Arizona Record* of Globe deals in an interesting way with the mining industry of the district. The text is well illustrated.

Mohave County

Charles S. Sprague and associates, who have taken over the Merritt, Yankee, and Dome properties, aggregating 150 acres in the heart of the Oatman district, announce that they will start active development at once with J. K. Turner, of the Jumbo Extension company, as consulting engineer for this merger, the Oatman United. Equipment which will be placed upon the ground will be of capacity adequate for working down to 1000 ft. depth.

Development has been started at the Oatman-Jumbo mine, midway between the United Eastern and Gold Road. A good outcrop occurs near a rhyolite dike.

Pima County

On February 21 the new railway between Gila Bend and Ajo, 40 miles, at the New Cornelia copper mine, commenced a regular schedule. Large quantities of structural material are arriving at the property. A machine-shop is being built.

At Gunsight, 15 miles south-east of Cornelia, an old centre, lead-zinc-silver ore has been opened.

CALIFORNIA

Amador County

To celebrate resumption of work at the old Eureka mine, between 2500 and 3000 people participated in the function at Sutter Creek on February 24. The event is said to be the greatest ever held in the county. Water is being removed from the old shaft to permit putting in the collar-sets.

Butte County

The Woolley manganese mine at Clipper Mills will supply ore for the smelter of the Noble Electric Steel Co. in Shasta county. The ore will be hauled in trucks to Oroville, and then railed to Heroult.

According to A. Buckbee of Utah the Forbestown district will be busy this summer, but a merger of properties is desirable for profitable work. He considers the ore suitable for cyanidation.

Colusa County

The first quicksilver that has arrived at Williams, passed through there last week from Wilbur Springs on its way to San Francisco. This marks the resumption of production in the Sulphur Creek district.

Mariposa County

To take over a lease or option to purchase 960 acres of the Fremont or Mariposa Grant, held by W. F. Deaner, the Elizabeth Mines was recently incorporated at Sacramento by Edward F. Dalton, R. Miller, and C. M. Coffing of that city, Edward M. Herberger of Sutter Creek, and Edward R. Solinsky of San Francisco. The capital is $500,000.

The Mountain King Mining Co.'s power-plant on the Merced river is described in the *Journal of Electricity, Power & Gas* for February 12 by Rudolph W. Van Norden. A brief history of the mine is also given. The dam is 88 ft. high, averaging 6 ft. high on the down-stream side, and 3 ft. on the up-stream side. The flume is 3737 ft. long, costing $4.128 per linear foot. It is semi-circular, 6 ft. 4 in. wide at the top, capable of carrying 3280 miners' inches, or 82 cu. ft. per second, with a grade of 5.28 ft. per mile. It was constructed in difficult country. The power-house includes a 450-hp. Francis scroll-case turbine, direct connected to a 350-kva. generator. The operating head is from 63 to 50 ft., depending on the state of the canyon where the plant is erected. The transmission-line is 8700 ft. long, carrying 4000 volts. The current is transformed to 440 volts for the motors, and 220 volts for the locomotive. At the mill are 11 motors of from 3 to 100 hp. The total cost of the power-plant was $35,169, or $88 per horse-power for 400 hp. delivered.

Nevada County

(Special Correspondence.)—The Orleans mine, adjoining the Empire, is being operated with Albert Crase as superintendent. The property was formerly a good producer, and is thought to contain the extension of the Empire vein. Unwatering of the 800-ft. shaft is proceeding, and sinking will continue to a depth of 1000 ft. It is equipped with a good hoist and pumping plant.

At the Union Hill developments are proceeding from numerous points, particularly at 600 ft., where good ore was uncovered last fall. Water has recently caused considerable trouble, but this annoyance is being rapidly overcome. Several small shipments of tungsten-bearing ore have been made. The North Star Mines Co. is preparing to erect a large office building near the Central shaft, and to transfer its offices to this point from the North Star mine. A large amount of new work is going on below the 6000-ft. level, with ore of excellent grade exposed at several faces.

Negotiations for the acquisition of the Oustomah mine, at Nevada City, by Utah people are proceeding. The Utah interests are represented by F. M. Wichman, of the Utah Metals Mining and Bingham-New Haven companies, and Charles T. Law. The Oustomah has been a good producer and is well equipped. It is operated by the Oustomah Mining Company.

The new plant being erected near Spenceville for the Queen Regent Merger Co. is rapidly nearing completion and will start treatment of copper-gold ore before the end of March. A

large amount of new underground work is proceeding, and indications are good for a steady output. Several copper claims in this district are being examined in the interests of San Francisco people. The ore frequently ranges from $20 to $50 per ton, with considerable gold present.

Grass Valley, February 20.

Although there is no shortage of men in the Grass Valley-Nevada City district, it is reported that a good number have left for the large copper centres where wages are now so high.

Development at the Golden Center mine at Grass Valley continue to be good, and additions to the mill are contemplated.

SACRAMENTO COUNTY

An extensive deposit of chromic-iron ore, in the Negro Hill district, 10 miles above Folsom, has been located by D. E. Wiley and others of that town.

SIERRA COUNTY

In the issue of February 26 it was stated that W. Hague was connected with the Mugwump Mines Co., operating near Alleghany; this is not correct.

SISKIYOU COUNTY

H. J. Barton of Yreka has re-opened an old quicksilver mine in this county, which will be managed by W. Forstner.

The mineral returns for 1915 now coming to the statistical division of the State Mining Bureau, under direction of Fletcher Hamilton, state mineralogist, are beginning to show some interesting figures relative to the production of the past year. Repties have been received from a sufficient number of the quicksilver mines of the State so that a fairly close estimate of the output can be made. This is placed at 12,450 flasks of 75 lb. each. The year's output was valued at $1,068,210, or nearly double that of 1914, which was $557,846 for 11,373 flasks.

THE QUICKSILVER FURNACE BUILDINGS AT NEW ALMADEN.

Some interesting developments are taking place at the present time as regards concentration of quicksilver ores, particularly at the Oat Hill and Aetna mines in Napa county, at the New Idria mine in San Benito county, the Kings in King county, and at the Oceanic in San Luis Obispo county. During a trip last week to the Napa County mines, the mining statistician of the Bureau, W. W. Bradley, observed several men with rockers concentrating cinnabar from the sand and gravel in the ravines and creeks below Oat Hill. At the present high price of quicksilver, they are making good wages. The unprecedented demand for information on California's quicksilver resources and particularly in regard to the metallurgy has exhausted the Bureau's stock of Bulletin No. 27, which was printed in 1908. It is the intention of the State Mineralogist to revise that bulletin in the near future, and bring it up to date. In this connection, an investigation is now under way relative to the possibilities of concentration, including also experiments on oil flotation of cinnabar. The results of these investigations will form a chapter in the new bulletin. Of importance to the metallurgy of quicksilver is the work being done at New Almaden, as described in the PRESS of February 19.

COLORADO

BOULDER COUNTY

The old Caribou silver mine at Cardinal has been acquired by the Caribou Mines and Mills Co., a Chicago corporation. The property was operated by the Cariman Mining & Milling company. A large production of tungsten ore continues from the county.

CLEAR CREEK COUNTY

The partly-erected Malm mill at Georgetown is to be completed at once, $50,000 having been secured by Mrs. Brownlee, of the Stanley mine at Idaho Springs. The first unit is of 50-ton capacity. The process is electrolytic.

TELLER COUNTY (CRIPPLE CREEK)

(Special Correspondence.)—Several new water-courses have been cut recently in the Roosevelt drainage-tunnel. For a few days the estimated flow from the portal was over 20,000 gal. per minute; however, the last official measurement recorded the flow of 16,000 gal., after the heavy flow had subsided somewhat.

The annual report of the Mary McKinney company shows the total net income for 1915 as being $27,517, with a cash balance on hand at December 31 of $92,132.

Work on the concrete foundations of the Dillon shaft has been started. The Granite Gold Mining Co. will shortly install a powerful electric hoist and compressor at the Dillon.

Cripple Creek, February 24.

IDAHO

BONNER COUNTY

Near Metaline Falls the Lead & Zinc Co. is treating 100 tons of ore daily, in charge of Lewis P. Larson. Mining is by open cut. A large quantity of ore has been developed. A 1000-ton mill is to be erected next summer.

BOUNDARY COUNTY

The Idaho Continental mine, 26 miles north of Bonners Ferry, will soon have its new 300-ton mill completed. It will replace the one burned in July, 1915. A 12-drill compressor and 1800-ft. aerial tram have also been erected. Shipments of crude ore average two carloads per week, assaying 58% lead and 25 oz. silver. This is hand-sorted. About 30,000 tons of milling ore is ready for treatment. The mine is considered an important one.

LEMHI COUNTY

At the Pittsburg-Idaho mine, near Gilmore, a good shoot of gold ore has been opened for 150 ft. in length, an 18-in. streak averaging over $700 per ton. The mine generally is in excellent condition.

MICHIGAN

The Copper Country

Diamond-drilling continues at the White Pine Extenston, recent cores showing rich ore with fine flaky copper similar to that in the White Pine mine.

The Onondaga Copper Co. has issued its report for 1915. On February 1, 1914, the company started No. 6 diamond drill hole with $71,675 cash. No. 6, 7, 8, and 9 holes were bored, the last on September 21, 1914. None of the lodes in the section drilled contained copper in commercial quantities. Work was stopped for a time, then resumed in the Nonesuch basin in July 1915. A hole in one corner passed through a barren lode at 1100 ft. Further work will be done. On February 1, 1916, the balance was $46,585.

Haulage of ore in the region is again normal, after a strenuous fight against snow and bad weather. The Mineral Range line is carrying ore from 11 mines, at the rate of over 500,000 tons per month. The system covers 100 miles of track in charge of T. W. Smith.

The Calumet & Hecla Mining Co. and subsidiaries report their January output as follows:

Ahmeek, 1,230,669; Allouez, 490,098; Calumet & Hecla, 5,736,261; Centennial, 138,061; Isle Royale, 851,270; La Salle, 150,469; Osceola, 1,223,484; Superior, 206,397; Tamarack, 505,789; and White Pine, 377,616 pounds of copper.

MISSOURI

Jasper County

The A. W. C. mine, west of Joplin, controlled by A. W. Canada and W. O. Cragg, was sold last week to J. T. M. Johnston of St. Louis and A. Gibson of Joplin, for $300,000. The transaction includes 40 acres, leases on 150 acres, three mills, and one being erected. Four years ago the original owners bought the 40 acres for $500. The ore is in sheet formation at a depth of 180 ft. The sale is one of the most important recorded in the district.

The February 20 issue of the *Joplin News Herald* is its 1916 mining and industrial number of 92 pages, in which is a mass of illustrated information dealing with mining and milling in the Missouri-Kansas-Oklahoma zinc-lead region.

MONTANA

Blaine County

(Special Correspondence.)—Gold mining at present is active in the Little Rocky mountains. A 200-ton cyanide plant is in operation at the August property near Landusky. Some ore assaying $40 per ton has been found.——The 600-ton cyanide plant of the Ruby Gulch company is working at capacity on ores that usually assay only $2 to $3 per ton, but the large orebody has permitted such low costs that the extraction of the gold has proved profitable.——The Beaver Creek company has completed a 150-ton cyanide plant, but it is not yet in operation. This company has developed a good orebody, and has been bonded to Eastern people.——Work is also being done on other mines and prospects in the district. About 120 men are now employed in these mines.

Landusky, February 21.

Lincoln County

(Special Correspondence.)—Vanadium ore has been found here under entirely new conditions, that is, in rock that was never known to contain vanadium. A prospector who is developing what is known locally as the Rainy creek copper claims, encountered a very tough rock that he could not break or name until a member of the U. S. Geological Survey staff visited the property and took samples of the rock to Washington. Analysis proved it to contain 4% vanadium, as well as other minerals. A geologist from Essen, Germany, came here, and made thorough tests of the ore and reported assays from 0.14 to 7.07% metallic vanadium. The 7.07% ore was from a sulphide ore not noticed or probably not seen by the American geologists. The ore occurs along both the foot and hanging walls of each of the 16 different veins in the claims, and is from 8 to 36 in. wide. The oxidized ore is a brownish-black and the sulphide a silver-white. The ore is abundant, and sometimes appears in the copper ore as well as in the country-rock or general formation. Both the oxide and sulphide of molybdenite is also found in quantity in these claims, which are in the foot-hills of the Cabinet mountains, about 2½ miles from the Great Northern railroad.

Libby, February 6.

Silverbow County

During January the Butte & Superior mill treated 49,428 tons of ore, yielding 10,536 tons of concentrate worth $101.6 per ton, an increase of $15, at a cost of $3.05 per ton.

Ore from the Butte-Alex Scott mine, now owned by the Anaconda, is being treated at the Washoe works in place of the East Butte smelter, where only one furnace is in blast. East Butte's flotation plant is treating 600 tons per day. The company may erect an acid plant to treat Butte-Duluth ore.

Anaconda is increasing its acid plant by 50 tons per day. Its Emma mine has been unwatered to 800 ft. Diamond-drilling in the Czaromah mine has cut a wide vein of zinc ore.

NEVADA

Esmeralda County

During January the Goldfield Consolidated company treated 31,000 tons for a profit of $59,061. Costs were $5.07 per ton. Development covered 3387 ft., at $5.06 per foot, revealing little of importance. The 50-ton flotation plant is almost ready for work.——The Nevada Metal Extraction Co.'s 150-ton flotation plant is also nearly complete.

Lincoln County

To treat a large dump of gold-silver-lead tailing at Bullionville, worth $18.50 per ton, the Prince Consolidated company of Pioche is to erect a 100-ton flotation plant. Anthony H. Godbe is president.

Nye County

During the past week Tonopah mines produced 8307 tons of ore worth $174,786. Bullion worth $91,741 was shipped. The Extension will pay 10c. per share, or $127,280, and the Belmont 12½c., equal to $187,500. The totals of these companies is $1,209,853 and $8,018,022 respectively.——During the second half of 1915 the Jim Butler's net income was $141,703. Silver stored amounts to $183,924, at 50c. per ounce.

Storey County

Development at the north end of the Comstock continues to give encouraging results. In sinking a winze below 2500 ft. in the Sierra Nevada, three feet of $25 ore has been cut.——From 2400 and 2500 ft. the Union Con. extracted 436 tons worth $10,000.——Prospecting at 2500 and 2700 ft. in the Mexican shows favorable porphyry and quartz. The mill treated 521 tons of custom ore averaging $23 per ton.——Work at 2700 ft. in the Ophir and Con. Virginia continues.——The Jacket-Crown Point-Belcher Mines Co. sent 754 tons of dump-ore to the mill.——The usual work proceeded at the Pumping Association's area.

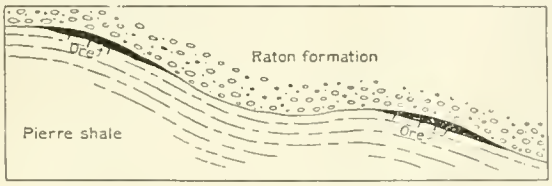
NEW MEXICO

According to John H. Leavell of Salt Lake City, southwestern New Mexico is busier than ever and optimistic. Mining centres dead for 20 years are making large profits, notably at Deming and Cook's Peak districts.

Colfax County

In Bulletin 620-N of the U. S. Geological Survey, Willis T. Lee describes the Aztec gold mine at Baldy. In 1870, 1904, and 1910, it was described by R. W. Raymond, F. A. Jones, and Waldemar Lindgren respectively. The mine was a famous

producer 45 years ago. A large body of high-grade ore was entered in August, 1914, and in the middle of 1915 the 10-stamp mill was crushing $107.60 ore. Concentrate is sent to the smelter. The property lies at an altitude of 10,000 ft., connected by wagon-road with Ute Park, the terminus of a branch of the Santa Fe railway. Placer mining was done extensively in 1867 on Willow creek, on the west slope of the mountain, yielding $2,250,000. In 1868 the source of this gold was found, the outcrop of the Aztec mine. About $1,000,000



SKETCH SHOWING OCCURRENCE OF GOLD ORE IN THE BALDY MINE, NEW MEXICO.

was extracted in the first four years. As a result of its production an English syndicate bought the Maxwell land grant of 1,750,000 acres. The rich ore became exhausted. In 1872 litigation commenced, and for over 40 years efforts were made to find other ore-shoots. In 1909 J. T. Sparks confined his attention to the quartzite-slate contact, and later on E. U. Deshayes found the present rich shoot. Some of the ore is found in small pockets and stringers in the conglomerate sandstone, but most of it that is worked at present is in the underlying shale, into which it extends for a few inches to five feet or more. The richest and largest bodies occur on the down-slope side of the crests of the minor folds, as shown in the sketch. The ore is free-milling.

UTAH

Beaver County

The Leonora Mining & Milling Co., operating in the Star district, has issued a report for 1915. Development amounted to 1050 ft. at $5.25 per foot. The manager, John Matson, is optimistic as to the future. Cash on hand amounts to $1747.

Juab County

The new plant of the Tintic Milling Co. is in operation. The Dragon Consolidated and Iron Blossom mines are supplying some ore. Storage-bins have a capacity of 2000 tons. The crusher and rolls, of 500-ton capacity, reduce the ore to ⅜ in. This is mixed with salt, etc., and further reduced. The fine ore is chloridized roasted in three Holt-Dern and one Knight-Christensen furnaces. The roasted product is then leached, and the metals precipitated.

Salt Lake County

Application has been made at Salt Lake City for a franchise to construct an electric railway from 10th street south on 21st east street, through Holiday, up Big Cottonwood canyon to the mines and Brighton. The road would be principally for hauling ore and supplies.

With the work under way and contemplated the Little Cottonwood district will produce more ore this year than ever before.

Tooele County

Another shipment of ore from the O. K. Silver mine 18 miles west of Mercur settled for 405 oz. silver and 0.02 oz. gold per ton.

VIRGINIA

Wythe County

The Beaver Valley Mining Co. is shipping zinc carbonate ore regularly from Ivanhoe, three carloads going out last week. S. L. Boggs is manager.

WASHINGTON

Chelan County

(Special Correspondence.)—The Holden Gold & Copper Mining Co. has leased and bonded its large and extensively developed property near Lake Chelan to Californians. Work is to be started on April 1. A larger compressor will be ordered and eventually a railway and smelter. The property was formerly bonded to Jay P. Graves for the Granby company, of Grand Forks, B. C., which did about 5000 ft. of development and opened a considerable quantity of low-grade copper-gold ore, but gave up its privileges when it started at the Hidden Creek mine.

Chelan, February 10.

Lincoln County

(Special Correspondence.)—It is reported that the Old Reliable, Wisconsin, and Dakota claims in the Egypt district have been sold to Salt Lake City people for $20,000. The ground will be equipped with machinery as soon as the weather permits. It is said that there is 50,000 tons of ore on the dump, averaging $15 per ton.

Crystal, February 10.

Okanogan County

(Special Correspondence.)—The Adirondack Mining Co. has installed at Sheridan an air-compressor, to drive six machine-drills, and a 75-hp. steam boiler and hoist. A dam is under construction to conserve 3,000,000 gal. of water, and a mill will be constructed in the spring. A contract has been awarded to Laurie Brothers to cut 1,000,000 ft. of lumber The mill is expected to cost about $8000. The company is employing eight men on a 30-ft. vein of low-grade milling ore, a 3000-lb. sample of which has been forwarded to Salt Lake City, to be tested for a suitable process. The ore contains about equal value in gold and silver.

A carload of antimony ore was shipped from the Gold Creek mine, in the Methow district, to Chicago. The company is preparing to build a small smelting plant this winter.

In a 4000 ft. adit which penetrates the northern slope of Palmer mountain a 12-ft. body of high-grade silver-lead ore was recently found at a depth of about 1600 ft. in the Ivanhoe mine, and another similar shoot was cut a short distance beyond it.

In the Myers Creek district work has been resumed at the Grant mine, on Copper mountain.

At the Gold Ax, Recco, Copper Queen, Eagle, and Rebecca mines in various districts a good deal of work is under way.

Sheridan, February 10.

Stevens County

The newly-organized Loon Lake Copper Co. is to unwater and develop the old Kemp-Komar mine near Loon Lake, 38 miles north of Spokane. Machinery has been ordered. The Blue Bird-Dupont claims adjoining are also to be developed.

CANADA

British Columbia

The preliminary review and estimate of mineral production of this province in 1915, compiled by Wm. Fleet Robertson, has been issued as Bulletin No. 1, 1916, by the Bureau of Mines. The publication covers 50 pages, which include some interesting matter. The yield of $29,299,564 is an increase of $2,910,739, mostly in copper and zinc.

The Trail reduction works of the Consolidated Mining & Smelting Co. is of considerable importance to this province, as it treats ore from the company's own mines and a large number of other companies, some in Washington. Copper, gold, lead, and silver are produced at present in the refineries, while soon the new electrolytic zinc plant will turn out good spelter. A great deal of electric power is used, and 1100 men

are kept busy. The company has purchased the common stock of the West Kootenai Power & Light Co., $75 par value of Consolidated stock for each $100 par value of Power stock.

During 1915 the Trail smelter treated 441,085 tons of ores and concentrates, 369,118 tons from the Canadian Consolidated mines, 40,971 tons from custom ores in the Province, and 30,966 tons from the United States, the Republic district of Washington contributing 25,409 tons. Metal output was as follows: 146,732 oz. gold, 2,900,639 oz. silver, 41,217,668 lb. lead, and 5,573,965 lb. copper, also some zinc.

According to O. H. Smith, general superintendent of mines for the Granby Consolidated company, there is considerable activity in several parts of the Province, especially on Alice arm, a branch of Observatory Inlet, on which is situated the Hidden Creek mine and Anyox smelter. An auxiliary steam power-plant is to be erected at Anyox to prevent a recurrence of reduced tonnage. In March the plant will treat 90,000 tons. On March 1 wages of miners were raised to $4.25 per shift, while copper is at 22c. The pay-roll includes 800 men.

The British Columbia Metals Corporation has been organized by G. Weaver Loper of the Lucky Jim Zinc Mines Co. to erect reduction works for complex ores at Nelson. Ore containing 25% zinc, 10% lead, and a little copper, gold, and silver, will be treated by the Malm process, in charge of Edward Dedolph of Kaslo.

The Standard Silver-Lead company of Silverton pays 2½c., or $50,000, on March 10. Bad weather is interfering with operations.

YUKON

Spring repair work is under way at the Canadian Klondyke and Yukon Gold companies' dredges.

KOREA

The Oriental Consolidated reports its January clean-up as $144,930.

MEXICO

(Special Correspondence.)—United States customs returns at El Paso show the following shipments from Mexico during 1915:

Product.	Tons.	Value.
Gold	....	$1,248,627
Gold ore	....	146,522
Silver	....	2,718,630
Silver ore	....	807,181
Copper ore	13,120	190,487
Copper matte	1,989	106,726
Copper bars	568	148,055
Lead	39,489	219,507
Lead bullion	165	10,071
Zinc	23,914	1,068,449

Imports during the first four months were heavy, then they dropped largely toward the end of the year, when the revolution was at its height.

El Paso, February 4.

During 1915, 10,218,788 bbl. of crude oil was shipped from Tampico to United States ports, compared with 11,746,371 bbl. in 1914.

SONORA

The Moctezuma company at Nacozari is to sink a new shaft; the deepest at present is 1300 ft. Two electric hoists of 2500-ft. capacity are to be installed. Mill concentrate is being dried to reduce freight on the railroad to Douglas. A third aerial tram to dispose of tailing, 2900 ft. long, has been erected. About 1500 men are employed. It is rumored that the company may erect a cyanide plant for its Churunihabi mines. Several mines in the Cumpas district are busy producing ore.

In spite of poor railroad facilities, shipments of products through Agua Prieta during January totaled 10,368 tons worth ₱2,250,300. From Nacozari came 9450 tons of copper worth ₱1,387,900. Silver was valued at ₱597,800, and gold ₱264,600.

PERSONAL

GEORGE E. FARISH is at Oatman.

F. A. HULL, of Seattle, is in California.

EDMUND JUESSEN has returned from New York.

C. S. HERZIG is now at 27 William street, New York.

LUCIEN S. ROBE, of Fairbanks, is visiting San Francisco.

WALTER LYMAN BROWN is in the London office of the Belgian Relief Commission.

L. D. FAY, of Oakland, will re-open the Twin Peaks quicksilver mine near Calistoga.

E. GYBBON SPILSBURY has been elected president of the Engineers Club, New York.

SPENCER C. BROWNE is now consulting mining engineer to the Midvale Steel Company.

WILL C. HIGGINS, editor of the *Salt Lake Mining Review* is making a tour of California.

LOUIS A. WRIGHT is on his way to Santiago, Chile, where he expects to remain for two years.

E. C. VOORHEIS is president and J. H. MACKENZIE is general manager of the Atolia Mining Co.

CHARLES T. KIRK, of Albuquerque, N. M., has been examining tungsten mines in Boulder county, Colorado.

W. L. FRASER has left the employ of the North Star Mines and is now with J. R. MCKINNIE, at Los Angeles.

OTT F. HEIZER, of Idaho Springs, Colorado, will be in Tuolumne, California, for the next two months.

P. D. BURTT, on his return to San Francisco from the Nevada Packard mine, has gone to Inyo county, California.

J. F. MITCHELL-ROBERTS is in New York. He will sail from San Francisco for Korea at the end of the current month.

W. J. MCATEE, formerly mill superintendent of the Nevada Hills Mining Co., is now with the Miami Copper Company.

WILLIAM C. RUSSELL has been appointed general manager for the Caribou Mines and Mills Co., Boulder county, Colorado.

WILLIAM A. BURR has been examining the Kroromiek mines in Madera county, California. He will be going shortly to China.

J. M. MITCHELL, mining engineer, formerly of Flushing, N. Y., is with the Homestake Mining Co. at Lead, South Dakota.

JOHN W. FINCH, in a New York hospital, is convalescing from typhoid most satisfactorily, his many friends will be glad to hear.

H. S. WEIGALL, formerly manager of the Kok Kang Kol mine in Korea, has obtained a commission in the Artists Rifle Corps, and will probably be attached to the engineering branch of that corps.

H. J. STANDER, who is doing flotation experimental work for the Arizona State Bureau of Mines, has been called to Brunswick, Georgia, for consultation work with the Yaryan Oil & Rosin Company.

C. W. MERRILL will give five lectures at the Mining Building of the University of California on 'Cyanidation.' The dates and times are as follows: at 4 p.m. on Monday, Wednesday, and Friday (March 6, 8, and 10), and at 5 p.m. on Tuesday and Thursday (March 7 and 9).

CHARLES WILLARD HAYES, formerly chief geologist to the U. S. Geological Survey, died on February 8, 1916, at the age of 57. He left the Survey to become mining geologist to the Mexican Aguila Oil Co. Previous to joining the Survey he was principal of a high school in Ohio. His first appointment on the Survey was in 1887 as an assistant and in 1902 he became chief. He was a graduate of Oberlin College and Johns Hopkins University, a member of the Geological Society of America, the American Institute of Mining Engineers, and the Mining and Metallurgical Society of America.

THE METAL MARKET

METAL PRICES

San Francisco, March 1.

Antimony, cents per pound	44
Electrolytic copper, cents per pound	27.75
Molybdenum; 90% MoS_2, per pound	$1.40
Pig lead, cents per pound	6.55— 7.50
Platinum: soft metal, per ounce	$88
Platinum: hard metal, 10% iridium, per ounce	$92
Quicksilver: per flask of 75 lb	$275—290
Spelter, cents per pound	22
Tin, cents per pound	43
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, March 1.

Antimony: 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	11.00
Magnesite: crude, per ton, f.o.b.	8.00
Magnesite: plastic, no iron and lime, calcined, ton	30.00
Magnesite: refractory, 11% iron, dead-burned, ton	35.00
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: minimum 60% WO_3, per unit of 20 lb	60.00—65.00

At Boulder, Colorado, $60 per unit is being paid for tungsten ore.

New York, February 25.

Antimony: 50%, per unit of 1%, or 20 lb., in 100-ton lots	$2.50
Tungsten: 60%, per unit of 1%, or 20 lb	70.00

EASTERN METAL MARKET

(By wire from New York.)

March 2.—Copper is quiet, but fundamentally strong; there are few sellers of lead, independents getting premiums; zinc is quiet, though London is strong.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Feb. 24	57.00	Jan. 19	56.68
" 25	57.00	" 26	57.14

June	56.43	49.03	....	Dec.	49.27	55.34	....

Small shipments of metal from Cobalt and Tonopah seem to indicate a desire to hold for higher prices. American silver operators maintain a bullish tendency.

London advises a good undertone. Reduced stocks at Bombay points to the necessity of fresh purchases, which should have a sustaining influence on London prices. Europe is buying fitfully, making an oscillating market.

COPPER

Prices of electrolytic in New York, in cents per pound.
